HEMIDACTYLUS BOUVIERI (Bouvier's House Gecko). CAPE VERDE: ILHEO SÃO NICOLAU: Ribeira Funda Valley, 250 m elev. (16°40'2.5"N, 24°20'35.1"W). 01 April 2007. G. Köhler. Verified by K. Klemmer. Forschungsinstitut und Naturmuseum Senckenberg (SMF 86991). First record for Ilheo São Nicolau (Schleich 1987. Spixiana Suppl. 12:1–75; Jesus et al. 2001. J. Herpetol. 35:672–675).

Submitted by **GUNTHER KÖHLER** (e-mail: gkoehler@senckenberg.de), **ANDREAS HERTZ, JAVIER SUNYER**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a.M., Germany; and **ALINE MONTEIRO**, National Institut for Research and Agriculture Development (INIDA), BP 84 – Praia, Santiago, Cabo Verde.

HEMIDACTYLUS GARNOTII (Indo-Pacific Gecko). USA: FLORIDA: Bay Co.: Ca. 3 km ESE Southport on E side Hwy 2321 (30°16'37"N, 85°36'28"W). 07 June 2005. John G. Himes. Juvenile collected on outside wall of building at 2230 h. FLMNH 144335. Verified by Kenneth L. Krysko. First record from the Florida panhandle and extends range ca. 320 km W of nearest record (Baker Co., Florida; Townsend and Krysko 2003. Florida Sci. 66:204–208). Three adults were also observed on outside walls and one adult inside building.

Submitted by **JOHN G. HIMES**, Florida Fish and Wildlife Conservation Commission, 3911 Hwy 2321, Panama City, Florida 32409, USA (e-mail: john.himes@myfwc.com); and **KEVIN M. ENGE**, Florida Fish and Wildlife Conservation Commission, 5300 High Bridge Road, Quincy, Florida 32351, USA.

HEMIDACTYLUS MABOUIA (Amerafrican House Gecko). USA: FLORIDA: Hillsborough Co.: Ruskin, I-75, Rest Area (27°40'56.64"N, 82°25'15.096"W, Datum WGS84, elev. 6.7 m). 08 August 2007. Kenneth L. Krysko and Brian J. Camposano. UF 151458–59. Verified by Kevin M. Enge. New county record (Townsend and Krysko 2003. Florida Sci. 66:204–208). Six other juveniles and adults observed near lights on walls.

Submitted by **KENNETH L. KRYSKO** and **BRIAN J. CAMPOSANO**, Florida Museum of Natural History, Division of Herpetology, University of Florida, Gainesville, Florida 32611, USA.

HEMIDACTYLUS TURCICUS (Mediterranean House Gecko). USA: GEORGIA: Baker Co.: On Coon Pond Road, 0.4 miles S of intersection with State Route 37 (NAD 83, UTM Zone 16N, E 748656.451 N 3468173.734). 03 March 2007. Matthew P. Greene. Verified by John Jensen. Four geckos observed among mobile home debris following a tornado touchdown on 02 March 2007.One individual deposited at Auburn University Natural History Museum (AUM 37433). New county record for this non-native species. Closest records are from Thomasville in Thomas County, Georgia ca. 70 km to the SE (Jensen et al. 2008. Amphibians and Reptiles of Georgia, *in press*).

Submitted by **MATTHEW P. GREENE, ERIN WILICHOWSKI**, **ANDY W. WHELAN**, and **J. LEIGHTON REID,** Joseph W. Jones Ecological Research Center, Rural Route 2, Box 2324, Newton, Georgia 39870, USA (e-mail: mgreene@jonesctr.org).

HEMIDACTYLUS TURCICUS (Mediterranean House Gecko). USA: TEXAS: Calhoun Co.: LaSalle Ranch, 2.09 road km W of FM 1289 on TX 185 (28°25'14.0"N, 96°32'58.7"W). 16 May 2007. D. Laurencio, J. A. Holm. Verified by James R. Dixon. Texas Cooperative Wildlife Collection, TCWC 91814. New county record (Dixon 2000. Amphibians and Reptiles of Texas. 2nd ed. Texas A&M University Press, College Station, Texas. 421 pp.). A second county record (TCWC 91815) was collected on 16 May 2007.

Submitted by **DAVID LAURENCIO,** Texas Cooperative Wildlife Collection, Department of Wildlife and Fisheries Sciences, 2258 TAMU, Texas A&M University, College Station, Texas 77843-2258, USA (e-mail: norops@tamu.edu); and **JAMES A. HOLM,** Crouch Environmental Services, Inc., 402 Teetshorn, Houston, Texas 77009, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: BURLESON CO.: Specimen collected south of Lake Somerville, Texas, under a rock on the shore of Lake Somerville and adjacent to Welch Park. Collected by KJ Lodrigue, Jr., and Graham S. Criglow (30°20'26"N, 96°32'55"W) on 18 April 2007. TCWC 91807. Verified by Toby Hibbitts. New county record (Dixon 2000. Amphibians and Reptiles of Texas, Second ed., Texas A&M University Press, College Station, Texas. 421 pp.). Fills in the hiatus between Brazos and Lee counties.

Submitted by **KJ LODRIGUE, JR.**, Texas A&M University, Department of Wildlife & Fisheries Sciences, College Station, Texas 77843-2258, USA.

HEMIDACTYLUS TURCICUS (Mediterranean House Gecko). USA: TEXAS: MATAGORDA CO.: Palacios, 1.1 road km N of Business 35 on TX 35 (28°43'27.0"N, 96°12'36.7"W). 26 June 2007. D. Laurencio, J. T. Williams. Verified by Toby J. Hibbitts. Texas Cooperative Wildlife Collection, TCWC 92437. New county record (Dixon 2000. Amphibians and Reptiles of Texas. 2nd ed. Texas A&M University Press, College Station, Texas. 421 pp.).

Submitted by **DAVID LAURENCIO** (e-mail: norops@tamu.edu) and **JOHN T. WILLIAMS**, Texas Cooperative Wildlife Collection, Department of Wildlife and Fisheries Sciences, 2258 TAMU, Texas A&M University, College Station, Texas 77843-2258, USA.

HOLBROOKIA PROPINQUA PROPINQUA (Northern Keeled Earless Lizard). USA: TEXAS: CALHOUN CO.: Matagorda Island, Aransas/Matagorda National Wildlife Refuge Complex (28°04'44.98"N, 096°50'02.94"W), 1 m elev. 26 June 2007. Peter Keller. Verified by Toby Hibbitts, Texas A&M University Texas Cooperative Wildlife Collection (TCWC 92458). New county/refuge record (Dixon 2000. Amphibians and Reptiles of Texas. 2nd ed. Texas A&M University Press, College Station, Texas. 421 pp.) Adult female specimen found active by day among the gulf beach primary dunes at the southern tip of Matagorda Island, and measured 55.5 mm SVL, tail 64.0 mm, weight 5.0 g. Several adults were observed at this location. Vegetation at the collection site consisted of Marshhay Cordgrass, Gulfdune Paspalum, Evening Primrose, and Fiddleleaf Morning Glory. We speculate that the appearance of *H. p. propinqua* on Matagorda Island is the result of the temporary closing of Cedar Bayou. This closing allowed the formation of a land bridge between Matagorda and San Jose islands where *H. p. propinqua* is a common species.

Submitted by **SHAWN F. McCRACKEN**, Texas State University, Department of Biological Sciences, 601 University Drive, San Marcos, Texas 78666-4615, USA (e-mail: smccracken@txstate.edu); **CHAD STINSON**, Aransas National Wildlife Refuge, 213 Royal Oak Drive, Rockport, Texas 78382, USA; **PETER KELLER**, Aransas National Wildlife Refuge, P.O. Box 294, Austwell, Texas 77950, USA; and **MICHAEL R.J. FORSTNER**, Texas State University, Department of Biological Sciences, 601 University Drive, San Marcos, Texas 78666-4615, USA.

LEIOCEPAHLUS CARINATUS (Northern Curly-tailed Lizard). USA: FLORIDA: MONROE CO.: Ramrod Key, 27338 St. Vincent Lane (24°39'31.248"N, 81°24'22.3956"W, Datum WGS84). 08 August 2007. Kenneth L. Krysko and Andrew P. Borgia. UF 151455. New island record (Meshaka et al. 2006. J. Kansas Herpetol. 17:6). Adult collected on limestone boulder. Four juveniles and three other adults were observed on boulders and Buttonwood Trees (*Conocarpus erectus*) on three adjacent properties, suggesting that this species is reproducing. Little Torch Key, 565 Barry Avenue (24°40'25.65119"N, 81°23'16.3608"W, Datum WGS84). 08 August 2007. Kenneth L. Krysko and Andrew P. Borgia. UF 151455. New island record. Juvenile collected on umbrella tree (*Schefflera actinophylla*). This species has been observed at this site since at least 2004. Specimens verified by Brian J. Camposano.

Submitted by **KENNETH L. KRYSKO**, Florida Museum of Natural History, Division of Herpetology, University of Florida, Gainesville, Florida 32611, USA; and **ANDREW P. BORGIA**, P.O. Box 4346, Key West, Florida 33041, USA.

SCELOPORUS LINEOLATERALIS (NCN). MÉXICO: COAHUILA: Municipalty of Torreón: Sierra de Jimulco, ca. 5 km NE of La Flor de Jimulco (25°06'52"N, 103°16'43" W), 1647 m elev. 19 August 2006. Gamaliel Castañeda-Gaytán. Verified by Edmundo Perez-Ramos. Colección Herpetológica del Museo de Zoología Alfonso L. Herrera, Facultad de Ciencias, UNAM (MZFC 19972). The specimen was found in a canyon covered by Chihuahuan Desert scrub vegetation. New state record, extending the known range of this species ca. 40 km (airline) SE of the type locality, 6 mi. NE Pedriceña, Durango (Smith 1936. Proc. Biol. Soc. Washington 49:87–96; Wiens et al. 1999. Evolution 53:1884–1897). This species was recently elevated from a subspecies of *S. jarrovii* (Bell et al. 2003. Acta Zool. Mexicana [n.s.] 90:103–174).

Submitted by **GAMALIEL CASTAÑEDA-GAYTÁN,** Reserva Ecológica Municipal Sierra y Cañón de Jimulco; BIODESERT, A.C. calle Blanco 35 Int. 1. Col. Centro. SERPENTES

ATRACTUS ZIDOKI. GUYANA: Potaro-Siparuni District, talus slope of Mt. Roraima beneath its northernmost promontory called "The Prow." (05°15'30"N, 60°43'30"W), ca. 2090 m elev. 08 April 2003. D. B. Means, J. Rivas, and M. Mayor. Verified by R. W. McDiarmid. Centre for the Study of Biological Diversity, University of Guyana Museum, Georgetown, Guyana (HR 701), plus 5 photographs deposited in the Florida Museum of Natural History, Gainesville, Florida (UF 150240). Found crawling on peaty soil of the El Dorado Swamp (MacInnes 1974. Climb to the Lost World. Hodder and Stoughton, London) across a recently cut footpath in tepui cloud forest dominated by small trees of *Bonnetia roraimae* with a dense groundcover of *Brocchinia tatei* tank bromeliads. Previously known from Amazonian Colombia, eastern Amazonia of Brazil, Suriname, and French Guiana. First country record, extends range about 450 km E of the closest known locality in Suriname and fills the distributional gap between Surinam on the

east and Colombia on the west (Hollowell and Reynolds [eds.] 2005. Bull. Biol. Soc. Washington 13:1–109; Hoogmoed 1980. Zoologische Verhandelingen, [175]:1– 47; Silva 2004. Rev. Acad. Colomb. Cienc. 28[108]:409–446).

Submitted by **D. BRUCE MEANS**, Coastal Plains Institute and Land Conservancy, 1313 Milton Street, Tallahassee, Florida, 32303, USA.

BOTHRIECHIS SUPRACILIARIS (Blotched Palm Viper). PANAMÁ: CHIRIQUI: Finca Santa Clara (Finca Hartmann) (08°51'N, 82°45'W), ca. 1300 m elev. 17 July 1980. Mrs. Hartmann. Verified by C. W. Meyers. AMNH 147743. First record from Panamá and a range extension of ca. 21 km SE of its closest known locality in adjacent Puntarenas, Costa Rica (Solórzano et al. 1998. Rev. Biol. Trop. 46:453–462). The snake was found in a coffee plantation.

Submitted by **JUAN E. DEJESUS**, Department of Herpetology, American Museum of Natural History, Central Park West at 79th St., New York, New York 10024-5192, USA; e-mail: Dejesus@amnh.org.

BOTHROPS JARARACA (Jararaca). BRAZIL: BAHIA. Municipalities of Ibicoara (12°24'S, 41°17'W), October 2001; Palmeiras (12°31'S, 41°33'W) August 2003; and Miguel Calmon (11°25'S, 40°35'W), November 2006. Collectors unknown. Verified by F. L. Franco. Coleção Científica de Serpentes do Museu de Zoologia da Universidade Federal da Bahia, Salvador, Bahia, Brazil (UFBA 1295, 1658, 1774–76, 1822). Species previously known from northeastern Paraguay, northeastern Argentina, and eastern Brazil from states of Rio Grande do Sul, Santa Catarina, Paraná, Mato Grosso do Sul, São Paulo, Rio de Janeiro, Espírito Santo, Minas Gerais, and Bahia (Sazima 1992. *In* Campbell and Brodie [eds.], Biology of the Pitvipers, pp. 199–216. Selva, Tyler, Texas; Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York; Puorto et al. 1992. Resumos do XVII Congresso Brasileiro de Zoologia: 442; Oliveira and Argôlo 2004. As Serpentes dos Cacauais do Sudeste da Bahia. Ilhéus, Editus). Northernmost record for the species, extends range ca. 205 km N from Amélia Rodrigues, the northernmost locality (Lira-Da-Silva et al. 2000. Livro de Resumos do 1º Simpósio da Sociedade Brasileira de Herpetologia, 2000. p. 65).

DRYMOLUBER DICHROUS. BRAZIL: ESPÍRITO SANTO: VITÓRIA (20°18'S, 40°19'W). 07 January 1996. J. L. Gasparini. Museu Nacional, Rio de Janeiro (MNRJ 4858). Verified by A. Velosa. LINHARES: Reserva Florestal da CVRD (19°10'S, 40°00'W). July 1993. A. A. Giaretta (MNRJ 10661, 10663). Verified by P. Passos. First vouchered records for the state. Until recently, this species was reported to occur only in the Amazonian region, where it is widespread (Peters and Orejas-Miranda 1986. Catalogue of Neotropical Squamata. Part. I – Snakes. Bull. U.S. Natl. Mus. 297:1–347). Subsequent records have extended its distribution eastwards and southwards into the Atlantic Forest domain in the states of Bahia (Franco et al. 1998. Répteis na Estação Veracruz. Veracel Celulose S.A., Eunápolis, Bahia. 39 pp.; Argôlo 2004. As Serpentes dos Cacauais do Sudeste da Bahia. Editus, Ilhéus, Bahia. 259 pp.), Ceará (Borges-Nojosa and Lima 2001. Bol. Mus. Nac. Rio de Janeiro, Zool. 468:1–5), and Minas Gerais (Passos and Brandão 2002. Herpetol. Rev. 33:324). The presence of *D. dichrous* at the Reserva Florestal da CVRD had been previously reported by Rocha (1998. *In* J. E. Santos [ed.], Anais do VIII Seminário Regional de Ecologia [vol. II], pp. 869–881. UFSCar, São Carlos), though no voucher material was mentioned. The record from Vitória extends the species' distribution ca. 270 km SE of the previous southernmost record, in the state of Minas Gerais (Passos and Brandão, *op. cit.*).

FARANCIA ABACURA REINWARDTII (Western Mudsnake). USA: TEXAS: VAN ZANDT CO.: DOR (59.2 cm SVL) found on Van Zandt County Road 2721, 1.28 km N of jct. with US 198, 05 June 2007. The closest permanent body of water to this specimen was a cattle tank within a pasture ca. 30 m away. R. Michael Burger. Verified by Carl J. Franklin. Voucher specimen deposited in University of Texas at Arlington (UTA R 55370). New county record (Dixon 2000. Amphibians and Reptiles of Texas. 2nd ed. Univer-

sity of Texas A&M Press, College Station, Texas. viii+421 pp.).

Submitted by **R. MICHAEL BURGER**, P.O. Box 4099, Dallas, Texas 75208, USA; e-mail: mvburger@dctexas.net.

LAMPROPELTIS GETULA GETULA (Eastern Kingsnake). USA: FLORIDA: LEVY CO.: Seahorse Key, beaches. 01 May 2004, 21 April 2007. David Wooten, David J. Hall, Cedric Worman. Florida Museum of Natural History, University of Florida, Gainesville (UF 141415, 151204). Verified by Kenneth L. Krysko. These are first records for Seahorse Key, one of numerous small Gulf Coast islands comprising the Cedar Keys, part of the Cedar Keys National Wildlife Refuge. One of us (DW) found a kingsnake on the south beach of Seahorse Key on 1 May 2004 (photo voucher UF 141415). The snake was wet and found crawling away from the water and shoreline, suggesting it had just swam or rafted to the island. A second snake was found by two of us (DH, CW) on the south beach in April 2007 (voucher photo UF 151204). The snake was found further west than the first specimen, near the transition from beach to hammock. Both of the snakes were healthy adults. There does not appear to be a resident population on Seahorse Key nor has the species been documented from other outer Cedar Keys. Both snakes were likely found soon after dispersing onto the island from the surrounding Gulf waters.

There is a large population of Florida Cottonmouth (*Agkistrodon piscivorus conanti*) on Seahorse Key. Many large specimens are present, especially near the bird rookeries (Wharton 1969. Bull. Florida State Mus., Biol. Sci. 14:227–272), probably attracted by fish carrion dropped or regurgitated from colonial nesting birds. Cottonmouths are ophiophagous, terrestrial, and achieve large body size. The presence of a robust population likely hinders other snake species from establishing populations on the island. Our observations suggest that *Lampropeltis getula*, like some other species of snakes (e.g., *Crotalus adamanteus*), are capable of dispersing considerable distances across Gulf waters. Eastern Kingsnakes are known from Cedar Key and the adjacent mainland, and specimens have been found in salt marsh near the coastline (e.g., UF 95544: 1 May 1976). We estimated minimum dispersal distances from satellite photos, considering both direct routes from the mainland and routes that involved "island hopping." In all cases, the maximum over-water distance is about 3 km.

Submitted by **DAVID WOOTEN**, **DAVID HALL**, **CEDRIC WORMAN**, and **HARVEY B. LILLYWHITE**, Seahorse Key Marine Laboratory, Department of Zoology, University of Florida, Gainesville, Florida 32611-8525, USA (e-mail: hbl@zoo.ufl.edu).

LAMPROPELTIS TRIANGULUM ELAPSOIDES (Scarlet Kingsnake). USA: SOUTH CAROLINA: GEORGETOWN CO.: Hobcaw Barony, 7.5 km SSE Georgetown. 31 March 2007. Travis W. Knowles. Verified by Alvin L. Braswell. Digital image deposited in the North Carolina State Museum of Natural Sciences (NCSM AN 12174). New county record.

Submitted by **JEFFREY D. CAMPER** (e-mail: jcamper@fmarion.edu) and **TRAVIS W. KNOWLES,** Department of Biology, Francis Marion University, Florence, South Carolina 29506, USA (e-mail: tknowles@fmarion.edu).

LAMPROPELTIS TRIANGULUM SINALOAE (Sinaloan Milksnake). MÉXICO: SONORA: Municipio de Yécora, 47.6 km (by Mex. Hwy. 16) W Yécora (28.40430°N, 108.67572°W), 720 m elev. 06 July 2006. E. Enderson and R. Bezy. Verified by George Bradley. UAZ 56576-PSV. First record from Yécora municipality and northernmost record in northwestern Mexico, extending the range ca. 183 km (airline) N from Guirocoba, Sonora (Williams 1988. Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulum*, 2nd revised ed. Milwaukee Public Museum, Wisconsin. x +176 pp.). The snake was DOR in tropical deciduous forest.

LIOPHIS FLAVIFRENATUS (Cope's Legion Snake). URUGUAY: DEPARTAMENTO TACUAREMBÓ: near "Los Argentinos," Rincón de Zamora (32°22'45"S, 55°32'38"W). 17 December 2006. S. Carreira and R. Maneyro. Colección Zoología Vertebrados, Reptiles, Facultad de Ciencias, Montevideo (ZVC-R 6417, adult male). Departamento Durazno: Ruta 6, ca. 10 km from La Paloma de Durazno (32°38'11"S; 55°27'53"W). 05 April 2007. I. Lombardo and S. Carreira. (ZVC-R 6495, adult, probable male – specimen damaged).

The species was known from São Paulo to Rio Grande do Sul (Brazil); from Paraguay to Argentina in the provinces of Corrientes, Chaco, Entre Ríos, Formosa, Misiones and Uruguay in Artigas, Salto, and Paysandú departments (Giraudo and Scrocchi 2002. Smithson. Herpetol. Infor. Serv. 132, 53 pp.; Carreira et al. 2005. Reptiles de Uruguay. DI.R.A.C. Facultad de Ciencias, Universidad de la República, Montevideo, 639 pp.). Carreira et al. (*op.cit.*) erroneously includes Tacuarembó and Cerro Largo in the distribution, but no specimens were reported in these areas, despite the fact that Meneghel and Achaval (1983. Bol. Soc. Zool. Uruguay, 2a. ép., 1:15–24) mentioned Tacuarí, Treinta, and Tres departments without vouchers. These new records extend the southern limit of the species ca. 100 km from the southern report in El Palmar National Park, Argentina (Giraudo 2001. Serpientes de la Selva

Paranaense y del Chaco Húmedo. L.O.L.A. Buenos Aires, Argentina, 328 pp.).

The defensive display observed in captivity and cited by Carreira and Meneghel (1999. Bol. Soc. Zool. Uruguay, 2a época 10:101–102) was observed in the field at the first contact with the specimen ZVC-R 6417.

Submitted by **SANTIAGO CARREIRA** (e-mail: carreira@fcien.edu.uy) and **IGNACIO LOMBARDO,** Secc. Zoología Vertebrados, Facultad de Ciencias, Iguá 4225, CP 11400, Montevideo, Uruguay (e-mail: ilombardo@fcien.edu.uy).

MANOLEPIS PUTNAMI (Ridgehead Snake). MEXICO: JALISCO: Municipality of Zapopan, Bosque La Primavera (20°39'28.88"N, 103°29'15.55"W), 1812 m elev. 20 September 2006. Ivan T. Ahumada-Carrillo. Verified by Fernando Mendoza. UTA Image 1045. An elevation record and state range extension ca. 200 km E from closest known localities in coastal Jalisco (Garcia and Ceballos 1994. Field Guide to the Reptiles and Amphibians of the Jalisco Coast, Mexico. Fundacion Ecologica de Cuixmala, A.C., Inst. Biologia, UNAM, Mexico, D.F. 184 pp.). The snake was found in leaf litter at the edge of an oak forest. This species is typically recorded from tropical sub-humid forests in the Pacific lowlands of México, although Johnson (1978. Southwest. Nat. 23:538) reported it from pine-oak forest on the Gulf versant of the Sierra Madre de Chiapas at ca. 717 m elev.

NERODIA FASCIATA PICTIVENTRIS (Florida Watersnake). USA: CALIFORNIA: SACRAMENTO CO.: City of Folsom, Humbug Creek from Oak Avenue Parkway to confluence with Willow Creek, downstream to Willow Creek confluence with Lake Natoma. This occurrence was originally documented as *Nerodia fasciata fasciata* (Banded Watersnake) by Balfour and Stitt (2002. Herpetol. Rev. 33:150, based on CAS 215207–215214). Subsequent genetic analysis and collections of numerous additional specimens indicate that the subspecies is *N. f. pictiventris* (Stitt et al. 2005 The Southern Watersnake [*Nerodia fasciata*] in Folsom, California: History, Population Attributes, and Relation to Other Introduced Watersnakes in North America. Final report to U.S. Fish and Wildlife Service, Sacramento, California). This subspecies is native to peninsular Florida (Gibbons and Dorcas 2004. North American Watersnakes: A Natural History. University of Oklahoma Press, Norman), and specimens from the introduced population matched the mitochondrial haplotype of those collected from Volusia, Pinellas, and Hillsboro counties in that state (S. A. Karl, pers. comm.). Recently, Fuller and Trevett (2006. Herpetol. Rev. 37:363) reported a reproducing population of *N. f. pictiventris* from Harbor City, Los Angeles County as a new state record for the subspecies (based on LACM 161154). This was reported prior to their knowledge of the updated information regarding the subspecific identity of the Sacramento County population.

STITT,** EPG Inc., 330 East 13th Street, Tucson, Arizona, USA (e-mail: estitt@epgaz.com); **MICHAEL M. FULLER,** Department of Ecology and Evolutionary Biology, University of Tennessee, 1416 Circle Drive, Knoxville, Tennessee 37996, USA (e-mail: mmfuller@tiem.utk.edu); and **TARA K. LUCKAU,** Arizona Research Laboratories, GATC, University of Arizona, 1041 E. Lowell St., Tucson, Arizona 85721, USA.

NERODIA SIPEDON (Northern Watersnake). USA: CALIFORNIA: PLACER CO.: Roseville, Kaseberg Creek, along margin of a large freshwater marsh adjacent to Woodcreek High School, NW of the intersection of Junction Blvd. and Woodcreek Oaks Blvd. Two female specimens (678 mm SVL and 906 mm SVL) were collected on 27 April 2007 by P. S. Balfour. CAS 235995–235996. Verified by Michael Dorcas, John Willson, and Whit Gibbons. One female was captured on land ca. 5 m from the water's edge and the other was captured in the water copulating with a male that subsequently escaped. Additional individuals of undetermined sex were also observed but were not captured. Analysis of mtDNA sequence data for these specimens was consistent with the field identification. When compared to published *N. sipedon* sequences (GenBank accession numbers AY523573 and AF384832) one of the specimens exactly matched 223 base pairs of the control region and had three single nucleotide polymorphisms (SNP) different in 546 base pairs of the ND2 region. The other specimen had one SNP in the control region comparison and five in the ND2 region (A. K. Buchanan and T. E. Edwards, unpubl. data).

The presence of several (at least five) individuals and observed copulation suggest that reproduction is occurring at the site. If so, this is the first recorded population of *Nerodia sipedon* in northern California. However, at least one additional *N. sipedon* may have been captured in California. Bury and Luckenbach (1976. Biol. Conserv. 10:1–14) and Jennings (2004. California Fish Game 90:161–213) both report a specimen of *N. sipedon* collected from an El Dorado Park, Los Angeles Co. (reported by Jennings [*op. cit.*] as LACM 109564). However, some confusion exists regarding this record, as two parks with lakes, located ca. 11.8 miles from each other, are known colloquially as El Dorado Park. Fuller and Trevett (2006. Herpetol. Rev. 37:363) suggest the specimen may actually be *N. fasciata*, potentially collected from Harbor Park (also known informally as El Dorado Park), the locality for Fuller and Trevett's (2006) *N. fasciata* population. We have not inspected LACM 109564 to verify its identity. However, no watersnakes have been observed by staff at El Dorado Park (as opposed to Harbor Park) since the collection of the one individual in 1976 (Richard James, pers. comm.). Thus, the current status of *Nerodia* at that locality is unknown.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blindsnake). USA: FLORIDA: Volusia Co.: New Smyrna Beach. 23 September 2006. Collected by Stacy Simmons. Verified by Kenneth L. Krysko, Florida Museum of Natural History, University of Florida. One individual found on floor of residence. UF 151313. First county record. Originally turned in to Division of Plant Industry (DPI), Florida Department of Agriculture and Consumer Services, Gainesville, Florida, as a "worm for ID" on 27 September 2006; Entomology Log No. 6879. It is not clear if this single specimen indicates an established breeding colony in this county. However, this invasive, parthenogenic exotic is established in other Florida counties and other regions of the world through its ability to disperse in the soil of transported potted plants (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington and London; Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publishing Company, Malabar, Florida).

Submitted by **LOUIS A. SOMMA**, Department of Zoology, PO Box 118525, 223 Bartram Hall, University of Florida, Gainesville, Florida 32611-8525, USA (e-mail: las@zoo.ufl.edu); and **PAUL E. SKELLEY**, Florida State Collection of Arthropods, Division of Plant Industry – Entomology Section, PO Box 147100, Florida Department of Agriculture and Consumer Services, 1911 SW 34th St., Gainesville, Florida, 32614-7100, USA (e-mail: skellep@doacs.state.fl.us).

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). USA: GEORGIA: Dougherty Co.: Private residence on Strout Avenue in Albany. 24 March 2007. Eric McGuire. GMNH 50035–50041. Verified by Elizabeth McGhee. First record of an established population in the state. Extends range ca. 100 km N of nearest record (Leon County, Florida; Krysko et al. 2005. Herpetol. Rev. 36:85–87). Seven individuals were collected while digging in sandy soil. In 2005, a single specimen (which was later lost) was collected from this same site and the author confirmed its identification. Other individuals were observed by the homeowner in 2006, but not collected. Together, these observations and collections suggest that an established population of this exotic species exists, having survived at least two winters.

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame Conservation Section, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA; e-mail: john_jensen@dnr.state.ga.us.

RHADINAEA FLAVILATA (Pine Woods Littersnake). USA: FLORIDA: Broward Co.: 17887 SW 8th Street, Pembroke Pines (25°59'58.8"N, 80°23'05.2"W). 08 April 2007. Christopher R. Gillette. Adult collected under artificial cover in the backyard of a developed lot in Misty Harbor at Silver Lakes subdivision. Verified by Kenneth L. Krysko. Florida Museum of Natural History photo voucher (UF 151119). New county record. Extends range ca. 76 km SSW from Lake Worth, Palm Beach Co. (UF 80245). Three other specimens have been found here.

Submitted by **CHRISTOPHER R. GILLETTE**, 143 Brescia Street NE, Palm Bay, Florida 32907, USA (e-mail: cgill002@fiu.edu); and **KEVIN M. ENGE**, Florida Fish and Wildlife Conservation Commission, 4005 South Main Street,

THAMNODYNASTES STRIGATUS. ARGENTINA: BUENOS AIRES: Partido de Berisso: 35°00'13"S, 57°34'58"W. 26 December 2003. D. O. Di Pietro and S. J. Nenda. Herpetological Collection of Museo de La Plata, Buenos Aires, Argentina (MLP-R 5318 adult female; SVL 374 mm, TL 117 mm). Verified by J. Williams. Species previously known from Paraguay, south and southeastern Brazil, Uruguay, and Argentina in the provinces of Misiones, northeastern Corrientes, Entre Ríos (associated with Río Uruguay), and northeastern Buenos Aires in delta region by occasional overflowing of Río Paraná (Giraudo 2001. Serpientes de la Selva Paranaense y del Chaco Húmedo, L.O.L.A., Buenos Aires, Argentina, 328 pp.; Giraudo and Scrocchi 2002. Smithson. Herpetol. Infor. Serv. 132:1–53). Southernmost locality, extends the known distribution along the coastline of Río de la Plata throughout the "Marginal Forest" ca. 110 km SE from San Fernando, Buenos Aires, which was the previous nearest known locality (Miranda et al. 1982. Asociación Cooperadora Jardín Zoológico de La Plata, Buenos Aires, 71 pp.; Williams 1991. Anfibios y Reptiles. *In* López and Tonni [eds.], Situación Ambiental de la Provincia de Buenos Aires. A. Recursos y Rasgos Naturales en la Evaluación Ambiental. C.I.C. La Plata, Buenos Aires, Argentina 1[4]:1–21).

Société d'Ornithologie de Polynésie « Manu »
BP 21098, 98719 Papeete, Polynésie française

French Polynesia encompasses five archipelagos: Marquesas, Society, Tuamotu, Gambier and Austral (sometimes called Tubuaï Islands). The terrestrial herpetofauna of French Polynesia has been reviewed by Ineich (1987a) and Ineich and Blanc (1989). Since these reviews, only one new report on the lizards of the Tuamotu Archipelago has been published (Nukutipipi Atoll, see Ineich 1990a-d). During a recent (October–November 2006) field trip by the SOP (Polynesian Ornithological Society; Expedition MANU SOP) to Niau Atoll (Tuamotu; for location, see Fig. 1), 10 lizards, including several species new for the atoll, were collected. Previously, five to six species have been reported from Niau Atoll (Ineich and Blanc 1989): *Emoia cyanura* sensu lato (then including the taxon now regarded as *E. impar*, as well as *E. cyanura* sensu stricto; see Ineich 1987b; Ineich and Zug 1992; Guillaume et al. 1994), *Cryptoblepharus poecilopleurus* and *Lipinia noctua* among skinks, and *Gehyra mutilata* and *Lepidodactylus lugubris* among geckos.

List of the MANU SOP expedition collected specimens are provided below:

Scincidae – 7 SPECIMENS

***Cryptoblepharus poecilopleurus* (Wiegmann, 1835) – 3 specimens**

MNHN 2007.0001, Coconut plantation, north of the village, coll. 25 October 2006 by Ludwig Blanc.

MNHN 2007.0006–07, Coconut plantation, south of the village, lagoon side, coll. 22 October 2006 by Ludwig Blanc.

***Emoia cyanura* sensu stricto (Lesson, 1826) – 3 specimens**

MNHN 2007.0004–05, Coconut plantation, south of the village, lagoon side, coll. 22 October 2006 by Ludwig Blanc.

MNHN 2007.0009, Coconut plantation, south of the village, coll. 17 October 2006 by Anne Gouni.

***Emoia impar* (Werner, 1898) – 1 specimen**

MNHN 2007.0010, West of the abandoned village of Tupana, marsh, coll. 27 October 2006 by Jean-François Butaud.

Gekkonidae – 3 SPECIMENS

***Gehyra oceanica* (Lesson, 1830) – 1 specimen**

MNHN 2007.0008, 5 km from the village, south of the ocean, coll. 20 October 2006 by Ludwig Blanc and Jean Durieux.

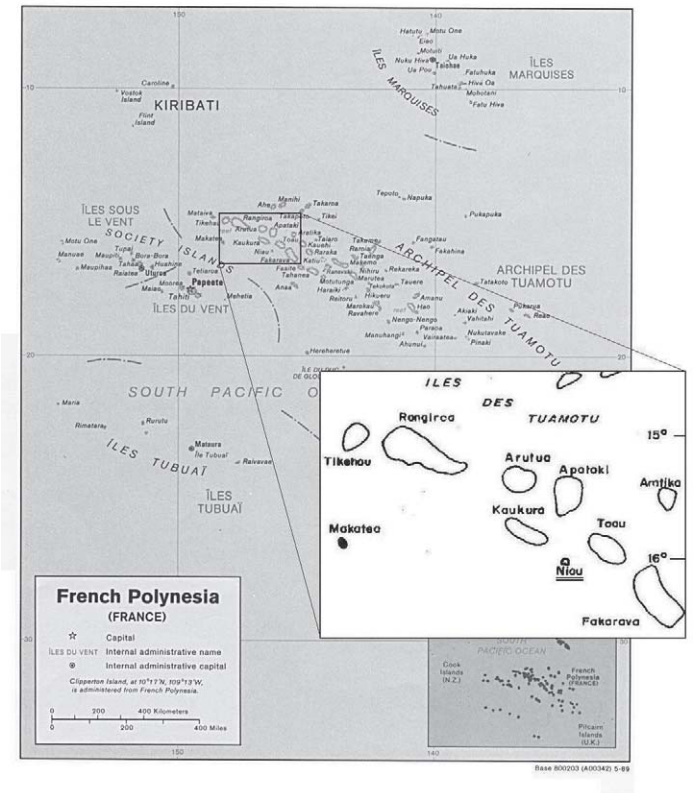

FIG. 1. Map showing the location of French Polynesia and Niau Atoll inside French Polynesia.

***Hemidactylus frenatus* Duméril & Bibron, 1836 – 1 specimen**

MNHN 2007.0003, in a house in the village, coll. 29 October 2006 by Ludwig Blanc.

***Lepidodactylus lugubris* (Duméril & Bibron, 1836) – 1 specimen**

MNHN 2007.0002, Coconut plantation, north of the village, bisexual female, coll. 25 October 2006 by Ludwig Blanc.

The MANU SOP Expedition material does not confirm the occurrence of one previously reported skink, *Lipinia noctua* (Lesson 1830) and one previously reported gecko, *Gehyra mutilata* (Wiegmann 1834) on Niau Atoll. Both are widespread and common on Pacific islands, and their absence probably reflects a collecting artifact. This recently collected material confirms for the first time, the occurrence of both *Emoia cyanura* and *E. impar,* as well as *Gehyra oceanica,* on Niau Atoll. It also confirms that bisexual *Lepidodactylus lugubris* populations still occur on the Atoll, and that they are not excluded by the recent invasion of the unisexual diploid clone A (see Ineich 1999). The most surprising result of the examination of that small lizard collection is the presence of *Hemidactylus frenatus* on Niau Atoll. This gecko was recently introduced into French Polynesia. It was not present on the five archipelagos around 1985–1986 (see Ineich 1987a; Ineich and Blanc 1989), and was first reported from Tahiti (Society Archipelago) in 1988 (Petren et al. 1993; Case et al. 1994). It has since spread rapidly and is now present on remote atolls of the Tuamotu Archipelago, such as Niau, although the precise extent of its current distribution in French Polynesia remain unknown. It is generally considered an aggressive species, with potential to have strong negative interactions with the local gecko populations. Such competition has been demonstrated in anthropophilous areas but not in natural habitats (Case and Bolger 1991; Case et al. 1994).

Range maps from Conant and Collins (1991) give the impression of a continuous range for certain species from the Blue Ridge Mountains of Georgia into the uplands of Alabama. Though corridors of rugged terrain (the Talladega Uplands and Gainesville Ridges *sensu* Wharton 1979) potentially serve as conduits for these species into the region of Alabama's highest elevations, the actual connectivity between the known segments of these species' ranges remains assumed. Several species illustrate this trend, and the ranges of species associated with montane habitats in Alabama and Georgia (e.g., *Rana sylvatica*, *Pseudacris brachyphona*, *Desmognathus aeneus*, *D. monticola*, and *Gyrinophilus porphyriticus*) are assumed to be either continuous or disjunct, when in fact the intervening region of Georgia (Polk, Haralson, and Paulding counties) is one of the least known herpetologically in the state (Williamson and Moulis 1994), and records for these species in these counties are lacking.

To address this lack of baseline information about an important region, we organized a "bioblitz" survey. To ensure robust volunteer turnout and enthusiasm, the bioblitz was conducted as a competition between four herpetological organizations (three university herpetological societies and the herpetology lab of an ecological research center). Each group organized a team and surveyed the region from 16–18 March 2007. The competition documented 30 total species and yielded 21 new county records for Georgia, including several for target species (e.g., those mentioned above).

There are several advantages to utilizing bioblitz competitions as survey techniques in record depauperate areas. First, herpetologists are typically competitive and often fancy themselves as good (if not the best) at finding and catching herpetofauna, a characteristic easily exploited in competition. Second, when a competition arises, it generates a larger turn out of skilled herpetologists than does a general collection trip. This provides a friendly yet competitive atmosphere, generating numerous records over a very short time period. We encourage others to utilize bioblitz competitions to survey other areas in need of assessment. All identifications were verified by Craig Guyer.

Caudata

Ambystoma maculatum (Spotted Salamander). PAULDING CO.: Paulding Forest Wildlife Management Area (PWMA, 33°56'48"N, 84°57'39"W). 17 March 2007. C. Camp, W. Smith, E. Timpe, and V. Johnson. AHAP-D 8.

Eurycea cirrigera (Southern Two-lined Salamander). POLK CO.: First order stream off Braswell Road 500 m W of Braswell (33°59'20.4"N, 84°58'09.5"W). 18 March 2007. S. Graham and E. Timpe. AHAP-D 11.

Desmognathus conanti (Spotted Dusky Salamander). HARALSON CO.: Small first order stream off of Coppermine Road (33°51'23.9"N, 85°04'20.7"W). 17 March 2007. S. Graham and A. Nelson. AU 37410.

Desmognathus monticola (Seal Salamander). HARALSON CO.: Small first order seep off Dugdown Road (33°53'53.1"N, 85°18'15.2"W). 17 March 2007. S. Graham and A. Nelson. AU 37408. POLK CO.: (34°00'54"N, 84°58'11"W). 18 March 2007. S. Graham and E. Timpe. AU 37407. DOUGLAS CO.: (33°44'52"N, 84°37'30"W). 16 March 2007. S. Graham, E. Timpe, and V. Johnson. AU 37406.

Notophthalmus viridescens (Eastern Newt). PAULDING CO.: Pond just north of Braswell Mountain Road ca. 800 m W of Lee Road (34°00'25.1"N, 84°54'30.0"W). 18 March 2007. J. Jensen, V. Johnson, and A. Nelson. AHAP-D 27.

Pseudotriton ruber (Red Salamander). POLK CO.: In a pool below a rock outcrop on Vinson Mountain Road 0.8 km N from the Paulding/ Polk County line (33°57'22"N, 84°59'56"W). 18 March 2007. K. Holcom and D. Van Dijk. AHAP-D 23.

Gyrinophilus porphyriticus (Spring Salamander). DOUGLAS CO.: (33°44'52"N, 84°37'30"W). 16 March 2007. S. Graham, E. Timpe, and V. Johnson. AHAP-D 17. PAULDING CO.: PWMA (33°56'48"N, 84°57'39"W). 17 March 2007. C. Camp, W. Smith, E. Timpe, and V. Johnson. AHAP-D 16.

Anura

Pseudacris brachyphona (Mountain Chorus Frog). DOUGLAS CO.: (33°45'06"N, 84°37'43"W). 16 March 2007. S. Graham, E. Timpe, and V. Johnson. AU 37401.

Testudines

Chrysemys picta (Painted Turtle). PAULDING CO.: Braswell Mountain Road approximately 480 m east of Lee Road (34°00'26.3"N, 84°53'32.0"W). 18 March 2007. J. Jensen, V. Johnson, and A. Nelson. AHAP-D 29.

Lacertilia

Eumeces fasciatus (Five-lined Skink). HARALSON CO.: In ruins of a house along Mountain View Road (33°54'15.0"N, 85°09'49.1"W). S. Graham and A. Nelson. 17 March 2007. AHAP-D 15a,b.

Sceloporus undulatus (Eastern Fence Lizard). PAULDING CO.: PWMA (33°59'05.7"N, 84°56'53.1"W). 17 March 2007. C. Camp, W. Smith, E. Timpe, and V. Johnson. AHAP-D 30.

Anolis carolinensis (Green Anole). PAULDING CO.: PWMA (33°59'05.7"N, 84°56'53.1"W). 18 March 2007. J. Jensen, V. Johnson, and A. Nelson. AHAP-D 28. HARALSON CO.: Small first order stream off Coppermine Rd. (33°51'23.9"N, 85°04'20.7"W). 17 March 2007. S. Graham and A. Nelson. AU AHAP-D 9.

Serpentes

Diadophis punctatus (Ringneck Snake). HARALSON CO.: Small first order stream off Coppermine Rd. (33°51'23.9"N, 85°04'20.7"W).

17 March 2007. S. Graham and A. Nelson. AHAP-D 13.

Carphophis amoenus (Eastern Worm Snake). HARALSON CO.: (33°52'27.9"N, 85°09'54.7"W). 17 March 2007. S. Graham and A. Nelson. AHAP-D 10.

Thamnophis sirtalis (Common Garter Snake). POLK CO.: (33°52'12"N, 85°11'11"W). 18 March 2007. S. Graham and E. Timpe. AHAP-D 26.

Storeria dekayi (Brown Snake). HARALSON CO.: (33°52'23.8"N, 85°09'49.1"W). 17 March 2007. S. Graham and A. Nelson. AHAP-D 12.

Nerodia sipedon (Northern Water Snake). POLK CO.: (33°55'09"N, 85°04'35"W). 18 March 2007. S. Graham and E. Timpe. AHAP-D 25.

Acknowledgments.—The bioblitz event could not have happened without the participation of C. Camp, J. Jensen, W. Smith, A. B. Nelson (Auburn University Herpetological Society); J. Maerz, A. Durso, D. Van Dijk, K. Holcomb, S. Starrett, J. Milanovich (University of Georgia Herpetological Society); M. Greene, A. Liner, A. Heupel, L. Reed (Ichauway Herpetology Lab); M. Black, B. Wynn, V. Lorenzi, G. Abhyankar, L. Bienenfeld, C. Dams, D. Mustafa, M. Quinones, and G. Stephenson (Atlanta Herpetology Club at Georgia State University).

Despite having one of the richest herpetofaunas (with at least 166 species) in the United States and several large academic institutions, Georgia remains one of the most poorly known states in terms of geographic distribution of amphibians and reptiles. To date, the most comprehensive assessment of amphibian and reptile distributions in Georgia is the under-circulated work of Williamson and Moulis (1994), in which large portions of certain species' ranges are assumed and lack verification. This report underscores the rewards possible to those interested in Georgia herpetofauna, and represents significant range extensions for three species, new county records for uncommon or secretive species, and the first published records in the state for two species.

Anura

Eleutherodactylus planirostris (Greenhouse Frog). THOMAS CO.: Found on the campus of Thomas College. 20 October 2002. S. Graham and L. Giovanetto. Verified by John Jensen. GMNH 49896. New county record.

Rana sylvatica (Wood Frog). MERIWETHER CO.: Found crossing Mt. Sinai road 5.6 km E of Gay at bridge over White Oak Creek in Joe Kurz Wildlife Management Area (33°07'25.8"N, 84°30'58.3"W). 17 January 2006. S. Graham. Verified by John Jensen. GMNH 49980. PIKE CO.: Found DOR on Dripping Rock Rd. 5 m N of bridge over Elkins Creek (33°58'14.6"N, 84°30'58.3"W). S. Graham. Verified by John Jensen. GMNH 49981. New county records. TALBOT CO.: Found on River Rd. 100m W of Flint R. and 1 km S. of Big Lazar Cr. in Big Lazar Creek Wildlife Management Area (32°48'00.2"N, 84º24'01.7"W). 2 February 2006. S. Graham. Verified by John Jensen. GMNH 49982. This new county record is currently the most southerly record known for this species (ca. 10 km S from the last published range extension by Camp and Pyron [2003]).

Caudata

Desmognathus apalachicolae (Apalachicola Dusky Salamander). MARION CO.: Found under logs in lowland swampy area 100 m N of St. Route 26 and Kinchafoonee Creek (32°18'24.9"N, 84°35'01.7"W). 29 March 2006, 27 August 2006. S. Graham and E. Timpe. Verified by John Jensen. GMNH 49993–49994. TAYLOR CO.: Found in lowland swampy area under log in small tributary of Whitewater Creek 1 km S of St. Route 137/Hobbs Road intersection. 11 March 2006. S. Graham and E. Timpe. Verified by John Jensen. GMNH 49988. The above county records extend this species' range into the upper Flint River basin (ca. 10–20 km E from the nearest populations in the upper Chattahoochee River basin, and ca. 115 km N of the nearest population in the lower Flint River basin), a significant extension for this narrowly endemic salamander. In addition, the habitat occupied by these populations (lowland gum swamp) is very different from the ravine habitat often cited as this species' preferred habitat (Petranka 1998). UPSON CO.: Found in mesic ravine along Double Branch 50 m E of Flint River at Camp Thunder Scout Reservation (32°56'59.3"N,84°30'56.7"W). 23 March 2006, 27 August 2006. S. Graham. Verified by John Jensen. GMNH 49995–49996. This county record is the first documentation of this species' occurrence in the Piedmont region and outside the Coastal Plain physiographic province.

Desmognathus conanti (Spotted Dusky Salamander). EFFINGHAM CO.: Found along seepages and mucky swamp 4.6 km SE of Springfield, 0.25 miles N of St. Route 225, and 50 m E of railroad crossing of Ebenezer Creek. S. Graham. Verified by John Jensen. GMNH 50001–50007. WAYNE CO.: Collected under litter 25 m N of Jaycee's boat landing at Altamaha River Bluff 8.05 km NE of Jesup (32°31'10.7"N, 81°16'50.6"W). S. Graham.

Verified by John Jensen. GMNH 50031–50033. These county records are significant southerly range extensions for this species in Georgia (over 100 km if considered disjunct), and suggest many populations might exist in seepages in the Coastal Plain with major rivers serving as corridors for dispersal from the Piedmont.

Eurycea chamberlaini (Chamberlain's Dwarf Salamander). CRAWFORD CO.: Crossing St. Route 341 50 m S of Roberta city limits (32°42'33.9"N, 84°00'35.8"W). 10 March 2006. S. Graham and E. Timpe. Verified by John Jensen. GMNH 49991. MERIWETHER CO.: 4.8 km NE of Gay crossing Mt. Sinai Rd. in Joe Kurz Wildlife Management Area (33°06'42.3"N, 84°32'43.1"W). 21 January 2006. S. Graham. Verified by John Jensen. GMNH 49989. TAYLOR CO.: Found crossing St. Route 208 6.2 km E of Talbotton (32°39'37"N, 84°20'45.8"W). 10 March 2006. S. Graham and E. Timpe. Verified by John Jensen. GMNH 49990. These represent the first state records for *Eurycea chamberlaini* in Georgia.

Hemidactylium scutatum (Four-toed Salamander). MERIWETHER CO.: Found crossing Mt. Sinai Rd. 4.8 km E of Gay in Joe Kurz Wildlife Management Area (33°06'41.8"N, 84°32'45"W). 17 January 2006. S. Graham. Verified by John Jensen. GMNH 49979. New county record.

Plethodon shermani (Red-legged Salamander). TOWNS CO.: Found under logs near the private residence of the late C. H. Wharton. Tate City, 200 m SW of the end of the Tallulah River Rd. in Georgia (34°59'25.2"N, 83°33'32.7"W). 30 April 2003. S. Graham, M. Meadows, C. H. Wharton. Verified by John Jensen. GMNH 49897–49898. First record of this taxon in Georgia. A previous county record of *Plethodon jordani* from near this locality (Jensen 2001) may have been this recently elevated species.

Plethodon websteri (Webster's Salamander). MERIWETHER CO.: Found under log on Buzzard's Roost, 50 m W of Flint River, 4.8 km S of St. Route 74 (32°58'08.9"N, 84°31'55.7"W). 5 March 2003. S. Graham and B. King. Verified by Craig Guyer. AU 35931. PIKE CO.: Found under rock on Buzzard Mountain, 14.5 km E of Molena, 50 m N of St. Route 109. 6 March 2003. S. Graham and B. King. Verified by Craig Guyer. AU 36378–36380. New county records.

Pseudotriton montanus flavissimus (Gulf Coast Mud Salamander). CLAYTON CO.: Found under log in Flint River floodplain 75 m NW of private residence on S. Hampton Ct. (33°28'5.0"N, 84°30'56.7"W). 24 October 2006. E. Timpe. Verified by Craig Guyer. AHAP-D 19. New county record.

Pseudotriton montanus floridanus (Rusty Mud Salamander). COFFEE CO.: Found in first order creek confluence with the Seventeen Mile Creek floodplain in General Coffee State Park, 50 m S of campground. 5 April 2006. S. Graham. Verified by Craig Guyer. AHAP-D 20. ECHOLS CO.: Found under log 50 m N of Hwy. 129, 150 m SE of its intersection with Howell Rd (30°49'41.2"N, 83°11'2.3"W). 29 October 2006. S. Graham, E. Timpe, L. Giovanetto. Verified by Craig Guyer. AHAP-D 24. New county records.

Pseudotriton ruber vioscai (Southern Red Salamander). STEWART CO.: Found in seepage under log 100 m N of St. Route 26 bridge over Bluff Springs Branch (32°18'19.1"N, 84°35'00.5"W). 27 August 2006. S. Graham. Verified by Craig Guyer. AHAP-D 21. SUMTER CO.: Found in seepage under log 10 m N of Hwy. 280, 5.15 miles E of Plains (32°02'58.0"N, 84°20'13.8"W). 29 March 2006. S. Graham and E. Timpe. Verified by Craig Guyer. AHAP-D 22. New county records.

Serpentes

Farancia abacura abacura (Eastern Mudsnake). MCINTOSH CO. (SAPELO ISLAND): Found crossing Nannygoat Rd. 300 m E of University of Georgia Marine Institute. 25 April 2003. S. Graham. Verified by John Jensen. GMNH 49899. This is the first record for Sapelo Island (Laerm et al. 2000).

Lampropeltis triangulum elapsoides (Scarlet Kingsnake). MCINTOSH CO. (SAPELO ISLAND): Found on road ca. 1.6 km NW of University of Georgia Marine Institute (31°24'30.1"N, 81°17'07.1"W). 29 June 2003. S. Graham. Verified by John Jensen. GMNH 49894. First record of this species on Sapelo Island (Laerm et al. 2000). TALBOT CO.: Found crossing Po Biddy Rd. 5 km W of Flint River (32°45'26.3"N, 84°24'07.4"W). 21 July 2006. S. Graham and E. Timpe. Verified by Craig Guyer. AHAP-D 31. New county record.

Lampropeltis triangulum triangulum (Eastern Milksnake). MURRAY CO.: Found under rock along rock "fort" archaeological structure at Fort Mountain State Park. 3 May 2006. S. Graham. Verified by Craig Guyer. AHAP-D 14. New county record.

Lampropeltis calligaster rhombomaculata (Mole Kingsnake). GORDON CO.: Found crossing St. Route 156, 1.6 km W of its intersection with Cash Rd. and Owens Rd.; 5.59 km E of Calhoun. 2 May 2006. S. Graham and D. West. Verified by Craig Guyer. AHAP-D 20. New county record.

Regina septemvittata (Queen Snake). CLAYTON CO.: Found DOR on Fitzgerald Rd. 2 km S from intersection with Mundy's Mill Rd. 24 September 2003. S. Graham. Verified by John Jensen. GMNH 49895. New county record.

Temperature-Dependent Sex Determination in Vertebrates, edited by Nicole Valenzuela and Valentine A. Vance. 2004. Smithsonian Books, Washington D.C., distributed by NBN/ Rowman & Littlefield (www.rowmanlittlefield.com). vi + 194 pp. Cloth hardcover. US $69.95. ISBN 1-58834-203-4.

BRETT A. GOODMAN
School of Marine & Tropical Biology
James Cook University, Townsville, 4811
Queensland, Australia
e-mail: Brett.Goodman@jcu.edu.au

In vertebrates, an individual's sex is influenced by a range of mechanisms, most of which can be grouped into one of two possible categories: genetic sex determination (GSD) and environmental sex determination (ESD); temperature-dependent sex determination (TSD) is categorized as a particular case of GSD. Nearly four decades have passed since the discovery that sex can be determined by temperature. *TSD in Vertebrates* is testament to fact that TSD research has blossomed since this time. In short, this title provides a synthesis of what is currently known about the ecological, physiological, molecular and evolutionary aspects of TSD. This book is arranged along four themes: prevalence of TSD in vertebrates; thermal effects, ecology, and interactions; evolutionary considerations; and conclusions: missing links and future directions. These sections are based on questions relevant to TSD: who possess TSD, how did it arise, how is it maintained, will it prevail, and what remains to be learned? In a brief introduction Valenzuela provides a short outline of the content of each Chapter and pertinent background on TSD in vertebrates, including a schematic figure illustrating the different patterns of TSD (i.e., TSD Ia, TSD Ib, TSD II).

In the first chapter, James Bull provides a past versus present perspective of sex determination with a view towards the future. He profiles how much of the early work that established the existence of TSD in reptiles, with particular emphasis on testudines, emerged and evolved from a sceptical academic environment. In fact, after learning of the existence of TSD as an undergraduate much of Bull's own research focus centered on disproving the existence of TSD in reptiles; presuming instead, that the apparent existence of TSD in this order was the result of differential mortality or from laboratory artefact. However, by 1978 Bull and colleagues

had adequate data to show that TSD occurred in at least four species of emydid turtles. In fact, it turned out there were two forms of sex determining mechanism within reptiles (i.e., sex-specific chromosomes and TSD). Bull acknowledges that one of the biggest challenges for workers of TSD in reptiles is how sex determined during a small phase of incubation influences fitness, particularly in long lived species. While the past two decades have provided a more thorough understanding of the taxonomic distribution of TSD, much of the original work has stood-up to past scrutiny. However, many problems still remain. He also highlights the importance of egg oestrogen content for sex determination; with particular emphasis on variation both within and among eggs and clutches and its influence on the sex of many species.

Chapter 2 by David Conover presents TSD in fishes. Due to the broad array of sex-determining systems identified both within and among fish species, definitions are provided for terms that are often used ambiguously. This chapter provides a summary of the TSD mechanisms in fishes and their evolutionary and ecological importance to natural systems, with the primary goals of highlighting gaps in our understanding of the adaptive significance of TSD to fish life history in nature and to providing motivation and advice for further investigation. Conover suggests that until studies of TSD move from the fishery to the wild we will remain ignorant of the ecology and evolution of what is perhaps the most diverse form of phenotypic plasticity in fish.

Chapter 3 (Michael Ewert et al.), focuses on modes, patterns and correlates of TSD in turtles. Using a combination of both previously published and original data the authors provide ample insight into the diversity of TSD in this group. They use rigorous statistical approaches to characterize TSD variation in patterns, pivotal temperatures, and transitional ranges both between and among species. Indeed, by examining and analyzing data for a few well studied species they were able to tease apart a number of other interesting patterns including, the correlation between pivotal temperature and transitional ranges, and the ecological significance and functionality of different transitions of geographic trends.

"Prevalence of TSD in crocodilians" is the title of Chapter 4 by Denis Deeming. Of the 25 species of living crocodilians, 12 posses TSD, and all are predicted to display the FMF pattern of TSD, due to their lack of heteromorphic chromosomes. However, the usefulness of TSD patterns observed in crocodilians are likely to be of limited value for understanding the TSD mechanisms of other reptiles, due to their closer phylogenetic affinities with archosaurs. Perhaps the most interesting aspect of this chapter is the list of potential explanations for the adaptive benefit of TSD in crocodilians. For instance, developmental asynchrony is presumed to be the result of male-determining factor (MDF) in the production of male offspring: eggs incubated above a threshold temperature for adequate duration of a specific thermally-sensitive period develop as male. Eggs that do not exceed this threshold during the thermally-sensitive period remain as female even at potential male developmental temperatures. In closing, Deeming suggests that much of the evolutionary success of crocodilians may be attributed to their ability to link gender, growth rate and other physiological conditions to environmental conditions.

In Chapter 5, Peter Harlow introduces considerable new data in a thorough review of the occurrence of TSD among lizard families (the group within which TSD was first described). In so doing, he expands on some earlier studies that lacked sufficient data to firmly conclude the presence of TSD. Finally, Harlow presents a probable adaptive scenario for TSD in a short lived, early maturing lizard—for which the effects of incubation temperature and seasonal timing of hatching are likely have the greatest effect on life-time reproductive success.

In the shortest chapter (Chapter 6; 6 pages), Nicola Nelson et al. provide an extensive overview of TSD in the two species of tuatara, using data from laboratory incubation and natural nests under field conditions. In short, this Chapter presents a nice mix of science and natural history information and observation. In closing, the authors acknowledge that while much of the well-known aspects of TSD in other reptiles remain unknown for tuatara, the information which has been gained up until now has greatly assisted management and conservation efforts of this order.

Thermal sex reversals in amphibians (Chapter 7; Dominique Chardard et al.), provides an in-depth perspective of sex determination in amphibians. For amphibians to date, the consensus suggests that sex determination is GSD, with the sex of some species being reversed at abnormally high or low temperatures. A description of the thermal effects of sex differentiation at the inter- and intra-specific level are presented; as few species have been examined in sufficient detail it is unknown how widespread this thermal lability is among amphibians. Indeed, to date, all work has focussed on the thermal effects of sex differentiation in the Anura and Urodela, with considerable research required on the Gymnophiona if the generality of thermal effects within the Amphibia is to be resolved.

Following this, Marshall McCue introduces readers to the 'General effects of temperature on animal biology' (Chapter 8), which provides a review of the general thermal biology of vertebrates. Included in a table, are definitions of some of the more commonly used terms, thermal limits, thermal sensitivity, and acute and chronic thermal effects on vertebrates. Understandably, there is much emphasis placed on ectotherms, with the discussion focused at varying levels of biological organization. This Chapter serves well to refresh the reader of biological phenomena important to those processes integral to temperature effects.

Relating the thermal effects influencing sex ratios measured under laboratory conditions to what happens in the field is the main focus of Chapter 9, 'Thermal models of TSD under laboratory and field conditions' (Arthur Georges et al.). Because the ways temperature affects incubation duration and sex determination is of central importance, the authors highlight three main steps to quantify the interaction between mean nest temperature and daily variation in temperature in the field, including: accommodating the interaction between mean nest temperature and daily variation in temperature, non-invasively identifying the thermosensitive period (TSP), and predicting the outcome of sex differentiation during complex thermal conditions. To resolve these issues, they present mathematical and descriptive models for TSD under different scenarios. They present information on the way temperature affects development and sex ratios under laboratory and field conditions, and provide information on how nest temperature data can be used to predict embryonic developmental trajectories, TSPs and the sex of hatchlings. The greater rate of embryonic developmental at higher temperatures implies that more development occurs above the mean incubation temperature than below it (Bull

and Vogt 1981; Pieu 1982). To ameliorate the difficulties associated with comparing results from controlled laboratory experiments and variable temperature regimes, Georges et al. present both a 'degree-hour approach' and 'constant temperature equivalent' (CTE) approach, that focus on development rather than absolute time.

Chapter 10, Phenotypic effects of incubation temperature in reptiles (Turk Rhen and Jeffrey Lang), reviews the effects of incubation temperature on the morphological traits of GSD and TSD species unrelated to sex, and how it relates to fitness. While there is considerable information on the biology of reptiles, much of the discussion of this chapter is somewhat removed from the rest of the book. However, much of the information presented is relevant for adaptive evolutionary explanations of TSD.

Chapter 11, 'The temperature-dependent sex determination drama: same cast different stars' (Allen Place and Valentine Lance) reviews current knowledge of the molecular networks associated with sex determination and differentiation in amniote vertebrates, beginning with mammalian and bird GSD systems and comparing these with TSD in reptiles. This chapter is well presented with detail and descriptions of genes, and their location on chromosomes for each family, and their putative functions.

Yolk steroid hormones and their possible roles in TSD is the title of Chapter 12 (Pamela Elf). Here, the focus is specifically on reptiles, a group that has received little work in terms of maternally derived hormones on sex differentiation, compared to mammals and birds. Hypotheses on mode of action, including published and unpublished observations on the dynamics of yolk hormones during development in TSD species are described. Indeed, it appears this area of research is beginning to gain momentum (Elf 2003; Radder et al. 2007).

Chapter 13 (Fredric Janzen and James Krenz) presents and discusses results of phylogenetically-based character analyses to determine whether TSD or GSD was the basal sex-determining mechanisms in vertebrates. The results suggest that while GSD appears ancestral, with TSD basal for sauropsids, the timing of its earliest appearance differs depending on the particular phylogenetic hypothesis chosen. Presumably, such ambiguities may be clarified as phylogenies gain increased resolution.

Chapter 14 (Nicole Venezuela) reviews hypotheses that attempt to explain the origins, diversification, maintenance and loss of TSD among vertebrate groups. Adaptive and neutral scenarios are discussed on the basis of whether they relate to genetic or environmental, maternal or paternal effects on gonadal sex and morphological traits, and whether they affect survival, fecundity or sex ratios. The distinction is made between short- and long-lived species with regards to the collection of relevant data and different hypotheses. Much emphasis is placed on examining the evolution of TSD using a comparative approach at varying levels of biological organization.

The final Chapter (Chapter 15; Girondot et al.) presents an improved age-structured model of population dynamics that incorporates various parameters that account for some of the unique traits of TSD taxa. A review of primary and secondary sex ratios is reviewed, and the suitability of alternative methods for measuring such ratios is provided. How primary and operational sex ratios influence population dynamics and differences in population sex ratios between TSD and GSD taxa is examined. Based on an unpublished phylogenetic analysis the most probable sex-determining pattern is inferred for various species for which this information is unknown. The authors also examine the reliability, using theoretical and empirical cases, of considering TSD as a factor in species decline. In closing, Valenzuela places the preceding fifteen chapters in perspective by highlighting gaps in the knowledge and potential areas of fruitful future research. She also provides an overall summary view and conclusions.

To close, this work brings together a wealth of information on TSD from a broad range of sources. The text is complemented by numerous tables (20), and figures (35), and there are relatively few typographical errors. Further, while recent work has identified TSD in a megapode bird (Goth and Booth 2004), it is absent altogether from the mammalian vertebrate class, suggesting the book's title is too general and may be misleading to some. I believe the price (US $70.00), while reasonable for an academic publication that includes contributions from many world-leading authorities, may be out of reach for many students. Given the rate at which TSD continues to attract research attention much of the content of this book is already dated. Nonetheless, this volume should prove useful to a wide range of biologists, interested in TSD and sex-determination mechanisms in general, and should become a core reference for those working on issues pertaining to TSD for years to come.

The present volume is the third generation of a series of amphibian and reptile guides for British Columbia published by the Royal British Columbia Provincial Museum, beginning with the handbooks of Carl (1943, 1944), and continuing through those of Gregory and Campbell (1984) and Green and Campbell (1984). It gives both the amateur and the professional a good handle on the British Columbian amphibian and reptile fauna (20 native and two introduced amphibians, 16 native and one introduced reptile).

The book is divided into an introductory portion and a field guide. The Introduction, 61 pages in length, consists of a series of short general discussions of various aspects of amphibian and reptile biology. In each, various features of the British Columbia amphibian and reptile fauna are noted, where appropriate. The Introduction comprises a good, if short, summary of amphibian and reptile morphology, physiology and ecology, and as such will be principally of use to readers with less knowledge of the more academic aspects of herpetology. This is not to say that it is unduly simple or watered-down; ectothermy, for instance, is discussed as a physiological strategy permitting the allocation of resources overwhelmingly into growth and reproduction while allowing a miniscule adult mass; thus we can have very abundant little salamanders in cool climates. Apparent gaps, such as the failure, in the section on Venoms, to mention tetrodotoxin in *Taricha*, are generally made up in the species accounts. A section on folklore quite properly deals mainly with examples of the rich First Nations oral traditions. The topics of where to find amphibians and reptiles, and how to deal with them in captivity, are, quite rightly, hedged with cautions on the legal issues surrounding all aspects of dealing with wildlife these days, and discussions of the ethics of the wild animal trade. Issues of conservation status and protection for British Columbia's amphibians and reptiles are dealt with briefly in the text, but a checklist of all of the British Columbian species features their present provincial (British Columbia Ministry of Environment) and federal (Committee on the Status of Endangered Wildlife in Canada) statuses. The Introduction ends with a call for more formal and informal studies of British Columbia's amphibian and reptile fauna, pointing out how much remains to be done, even at the level of basic ecology and ascertaining range limits. The interested amateur is referred to an appendix listing government and academic contacts for formal reporting of observations. Rapid and wide dissemination of locality records is encouraged.

The Introduction is peppered with small pen-and-ink or pencil drawings of various British Columbian amphibians and reptiles, generally germane to the adjacent text. These are delicate and detailed, the result of close attention to anatomical detail and characteristic attitudes.

The field guide portion consists of keys and individual species accounts. These are laid out systematically, and are restricted to native species and established exotics. Species with occasional, accidental or possible occurrences in the province are dealt with elsewhere. A dichotomous key to the adults of each order to be found in British Columbia precedes the species accounts of that order, with some simple clear illustrations of the morphological features mentioned (illustrations of a salamander and an anuran with limbs adpressed would have been useful here; also, the figure of a frog's face labeled "eyes vertical" (p. 109) might better have been labeled "upturned eyes", as this is the expression used in the text); technical terms used in the keys are also defined in the Glossary at the end of the book. A field key for snakes is followed by a laboratory key. There are no keys for amphibian larvae, and the reader is, quite properly, referred to Corkran and Thoms (1996) for these. Each species account is headed by the currently accepted colloquial and Latin binomial (Green, 1999; Gregory and Gregory, 1999; Crother et al., 2000; Crother et al., 2003; the revisions of Frost et al., 2006 are not accommodated) for the species, with alternate colloquial names listed immediately below. These are generally followed by a short paragraph summarizing recent relevant taxonomic changes, general remarks on cardinal features of the genus or family if this species is the first or only such to be dealt with in the book, its status in British Columbia, and the like. A description of the species' appearance follows; for amphibians, larval morphology and development are also briefly described. A color plate (all of these are bound in a single signature) is associated with each description. These are generally sufficient to identify a specimen in the hand to species, and for the most part the animals are suitably framed and represent British Columbia populations. Plates illustrate cases of possibly confusing polymorphism (*Ensatina eschscholtzii*, the three *Thamnophis* species, juvenile and adult *Coluber constrictor*, neotenic and terrestrial *Dicamptodon tenebrosus* and *Ambystoma tigrinum*). A short list of the distinguishing features comes immediately after, longer in cases (such as the three species of *Thamnophis*, or the four species of "brown spotted frogs") where there is scope for misidentification; the authors are quite frank about the possibilities for confusion here. The section on habits briefly delineates what is known of habitat preferences, diet, behavior, predators, etc., with reference particularly (and explicitly) to what is known from the literature on British Columbia populations; the authors note more than once that

this is not extensive for some species. A section on breeding describes courtship behavior, calls (for anurans), oviposition, clutch size and characteristics, and again for amphibians, a few remarks on larval morphology, behavior and development. This is followed by a short note on subspecies, if any, and which are represented in British Columbia, and a description of the geographic distribution, both extralimital and within the province; this last is also illuminated by a dot map of documented provincial localities for the species in question (introduced and native populations are distinguished by symbol). Each account is rounded off with a short list of relevant citations, generally but not always from the primary literature and again with an emphasis on British Columbia. A detailed pen-and-ink drawing of an adult representative of the species is either within the species account or on the preceding facing page. These are done with a good eye and a careful hand, and for most of the species would be sufficient to identify specimens in the hand, without further reference to the text or keys; the exceptions are the species which would take some close examination and pondering anyway.

The species accounts are generally clearly-written and unambiguous, and there is little to find fault with. I was somewhat puzzled to note that the picture of the Boreal Chorus Frog (*Pseudacris maculatus* – p. 131) had its lateral stripe terminate in the axillary region, rather than (as described in the text) at the groin. This is more than compensated for by the description of the leopard frog's breeding call as resembling "a fart in a tight pair of chest waders" (p. 151). One can only defer to the authors' experience here. A few omissions rather surprised me. For instance, there is no reference to the caudal glandular ridge and the dermal toxin produced by the Long-toed Salamander (*Ambystoma macrodactylum*), although these features are strikingly evident to anyone who handles one for any length of time. However, these and the few other such lacunae that I noted are of no great consequence. Even a neophyte would be able to identify a capture to species using this book, would be reliably informed about its biology, and would be clearly directed to further sources of information on it.

The species accounts are followed by a short section on amphibians and reptiles that might be encountered in British Columbia—possible undiscovered natives (such as the Cascades Frog, *Rana cascadae*), exotics which survive in the province but do not successfully breed, such as Red-eared Slider Turtles (*Trachemys scripta*), and possible accidentals such as Loggerhead Sea Turtles (*Caretta caretta*). Common unestablished exotics and accidentals may be described in sufficient detail for diagnosis, but possible undiscovered natives are simply listed. The guide ends in a Glossary, its definitions clearly-written and adequately supplementing the text, and a Bibliography, divided into Additional Reading (field guides and general works) and References (sources, mainly primary literature, cited in the text).

A good regional field guide should be the reference of first resort within its geographical limits. The present volume mostly succeeds in this—it must be supplemented with the easily-available Corkran and Thoms (1996) for larval identification, but the latter's keys are difficult to improve upon. I can recommend Amphibians and Reptiles of British Columbia without hesitation to anyone interested in the amphibian and reptile fauna of western Canada. It serves as a useful benchmark to what's currently known about British Columbia's amphibians and reptiles, actively and constructively solicits new observations from all and sundry, and will encourage further research.

The Valle de Tehuacán-Cuicatlán, actually a complex of five smaller valleys, comprises one of Mexico's four desert systems (Briones 1994). One of these, the Valle de Zapotitlán de las Salinas, may well be considered the pearl of the Pueblan high desert. I first saw this magical place nearly thirty years ago when Jonathan Campbell and I camped near the home of the Pacheco Gil family along the Río Salado. It was then that I got my first look at snakes like *Lampropeltis triangulum campbelli* (as yet undescribed), *Leptotyphlops maximus*, and *Trimorphodon tau*. Some of my fondest memories include wandering among the *Agave-Beaucarnia-Yucca* associations (*izotales*) along the high ridges in search of *Ophryacus melanurus*, *Phrynosoma braconnieri*, and *P. taurus*. As a plant enthusiast, the presence of three endemic *Dioon* species made things all the more special.

Zapotitlán is rough country, and its wildlife can swelter as much as two years between rains. The Pacheco Gil family claimed there were turtles in the basin. Standing there listening to them while the dust blew, looking at their meager supply of drinking water, it was simply impossible to believe that a turtle could exist anywhere near the spot. So, after a bit of banter, we told the family we would come by in a month, on our way back north from Guatemala, to see what they had produced. And wouldn't you know it, four weeks later we stood speechless before them as they chuckled and handed up a dozen *Kinosternon integrum*. One can scarcely imagine the type of existence led by these turtles, inert and buried for most of their lives.

Recently the basin has been the object of excellent investigations dealing with vegetation, physiography, and habitat destruction (among others: Arias et al. 2001; Montoya-Ayala 2000; Osorio et al. 1996; Valiente-Banuet et al. 2000; Villaseñor et al. 1990). It is recognized as a world center for megadiversity and endemism by the IUCN (Dávila et al. 1991, 2002). Ironically the fauna has been little studied, so when Canseco Márquez and Gutiérrez Mayén (1996) published a list of 32 species of reptiles and amphibians and announced their plans to produce a comprehensive field guide to the region (ARVZ), it was good news, indeed.

While the authors were engaged in fieldwork for their book, Mata-Silva (2003) published a comparative study examining populations of amphibians and reptiles in the basin versus the impact of habitat destruction. Subsequently, Woolrich Piña et al. (2005) increased the species total to 35 and presented a nicely illustrated guide that unfortunately is already out-of-print and difficult to obtain. Publication of ARVZ expanded the list for Zapotitlán de las Salinas to 40 species comprising 7 amphibians and 33 reptiles in 32 genera representing 17 families.

Both guides contain illustrated keys and ARVZ is noteworthy for its excellent line drawings of snakes. Despite including comprehensive color photographs, neither guide provides captions or locality data for the specimens illustrated, or a "Remarks" section. Woolrich Piña et al. (2005) includes a useful summary of comparative literature and ARVZ contains interesting notes about distribution and natural history for most species. Still, the reader is left clueless as to why the species recognized as *Ctenosaura pectinata* by Woolrich Piña et al. is referred to as *C. acanthura* in ARVZ.

The two guides provide extensive illustrations and descriptions of habitats and vegetation and ARVZ includes maps of the area. Scientific nomenclature used in ARVZ is more current than that used by Woolrich Piña et al. Inclusion of subspecies would have rendered both guides more useful. Area of coverage is specifically the Zapotitlán Basin in Woolrich Piña et al., while ARVZ includes surrounding ridges. Inasmuch as the latter only represents five additional species, the broader coverage provided by ARVZ makes more sense.

Why review a guide with such limited coverage? Because the region is unique and important, the habitat is fragile, and the 40 species are so difficult to obtain that their mere acquisition represents as much work as a broader assemblage would entail. The authors of ARVZ have done a nice job in treating this important herpetofauna and presenting their data in a readable, informative manner.

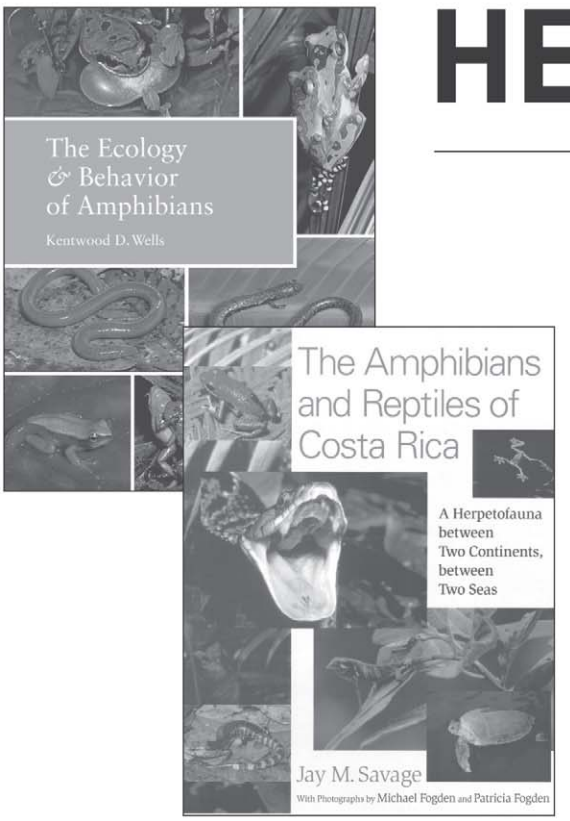
CONTRIBUTIONS TO THE HISTORY OF HERPETOLOGY



Volumes 1 (1989) and 2 (2007)

Volume 2 in this series was published by SSAR in July (see *Herpetological Review*, June 2007, p. 130, and *Journal of Herpetology*, September 2007, p. 544, for ordering details).

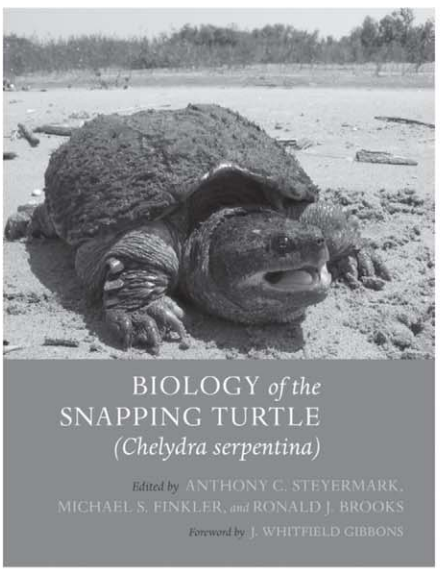
Note: Volume 1, out of print by 2000, has now been put on the web for public access at www.ssarherps.org (click on "Publications").

HERPETOLOGY

from chicago

THE ECOLOGY AND BEHAVIOR OF AMPHIBIANS
Kentwood D. Wells

"Kentwood D. Wells is probably the only person in the world with such a breadth of knowledge and grasp of the literature in amphibian biology to even attempt such a monumental book. Indeed, I consider *The Ecology and Behavior of Amphibians* to be a masterpiece in the field. I have been awaiting this book for the last fifteen years and, after reading it, I am not only satisfied with it but am amazed by the clarity of writing and the wealth of information presented. This is a magnificent book."—Robert Jaeger



CLOTH $75.00

THE AMPHIBIANS AND REPTILES OF COSTA RICA
A Herpetofauna between Two Continents, between Two Seas
Jay M. Savage
With Photographs by Michael Fogden and Patricia Fogden

"A magnificent and unparalleled book. I know of no other herpetological work that . . . is blessed with greater breadth of coverage, attention to detail, freedom from error, quality of illustration, or extent of appeal."—Larry David Wilson, *Herpetological Review*

BIOLOGY OF THE SNAPPING TURTLE *(Chelydra serpentina)*

edited by Anthony C. Steyermark, Michael S. Finkler, and Ronald J. Brooks
foreword by J. Whitfield Gibbons

The name "snapping turtle" conjures up images of powerful, prehistoric-looking beasts that lurk in the dark waters of local swimming holes. Beyond its status as childhood legend, *Chelydra serpentina* is one of the most interesting reptiles of the New World. One of our largest turtles, this animal has a nasty bite, weighs up to thirty-five pounds, and can lay as many as one hundred eggs. Due to its wide distribution, abundance, and large reproductive output, the snapping turtle has become one of the most extensively studied species of reptiles.

This volume synthesizes all that is known about *C. serpentina*, the common snapping turtle, to provide an up-to-date and comprehensive resource on the species' evolution, physiology, behavior, and life history. Anthony C. Steyermark, Michael S. Finkler, Ronald J. Brooks, and a team of experts detail the systematics, energetics, growth patterns, sex determination, and population genetics of snapping turtles and devote special attention to the fossil record of the snapping turtle family Chelydridae.

The first broad biological treatment of the common snapping turtle, this is the definitive reference for anyone working with this fascinating reptile.

248 pages, 15 halftones, 48 line drawings
$75.00 hardcover

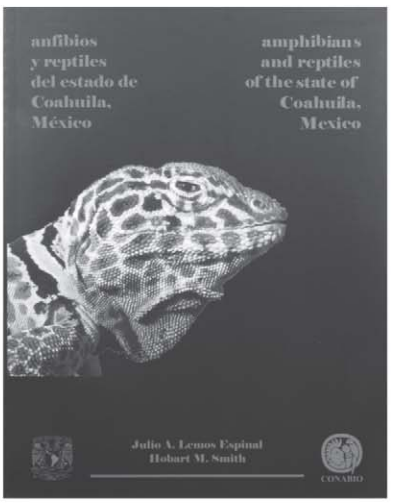
First Announcement

Current Research on Herpetofauna of the Sonoran Desert IV

April 11–13, 2008



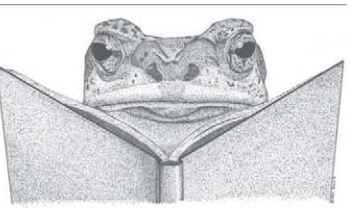
Tucson, Arizona

The Tucson Herpetological Society (THS) and co-sponsors are pleased to announce the fourth meeting of *Current Research on Herpetofauna of the Sonoran Desert* (CRHSD). The first CRHSD meeting was held at The Phoenix Zoo April 9–10, 1999. This conference, co-sponsored by the Arizona Game and Fish Department, Arizona State University West, and The Phoenix Zoo, was hugely successful with a number of would-be registrants turned away due to seating limitations. Since then, this event has been held every 3 years and has grown in interest and enthusiasm. The second CRHSD meeting, sponsored by the THS and others, was held in April 2002 in Tucson, and the third meeting was hosted by ASU in Phoenix in April 2005.

The goals of this fourth meeting are two-fold: 1) dissemination of information concerning research on the herpetofauna of the Sonoran Desert (in the states of Arizona, Sonora, and on the Baja California peninsula and gulf islands); and 2) provide opportunities for social interaction and dialogue among meeting participants.

The meeting will begin on Friday evening with an Icebreaker Social Event. Scientific Sessions on Saturday and Sunday will include approximately 30–40 oral presentations as well as poster presentations. Saturday evening will include a Social Hour followed by a Banquet. There will be three invited speakers at the meeting. Harry W. Greene, Professor at Cornell University, will open the Scientific Session on Saturday morning. Cecil Schwalbe, of the U.S. Geological Survey, will be the Banquet speaker on Saturday evening, and Edward O. Moll, Professor Emeritus at Eastern Illinois University and Adjunct Professor at the University of Arizona, will be the featured speaker on Sunday morning.

The CRHSD IV second announcement will be made in the fall and will include registration information, call for papers, and information on accommodations at the Inn Suites Hotel. All information is available on the THS web site (www.tucsonherpsociety.org). We hope you will mark your calendar and plan to attend what will be the continuation of an exciting and informative scientific meeting.



Amphibians & Reptiles
of the State of
Coahuila, Mexico

Julio A. Lemos Espinal & Hobart M. Smith

The most comprehensive text on the amphibians and reptiles of the state of Coahuila, Mexico. Contains taxonomic keys, in depth species descriptions, color photographs, gazetteer, dot distribution maps, and localities of collection. Complete text in both Spanish and English

Specifications: xii, 552 pages, 8½ x 11 inches. Paperback (ISBN: 970-9000-40-3) $90.00 + postage.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution or Natural History notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order form will be sent prior to publication. These are also available upon request from the Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pdf/Adrates.pdf).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Central Michigan University, Department of Biology, 217 Brooks Hall, Mt. Pleasant, MI 48859, USA. Periodicals postage paid at Mt. Pleasant, MI 48859 and at additional mailing offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Allen Press, Inc., P.O. Box 1897, Lawrence, KS 66044, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Regarding missing or damaged issues, please notify *Herpetological Review*, Allen Press, Inc., P.O. Box 1897, Lawrence, KS 66044, USA (tel. 785/843-1234 or e-mail: herps@allenpress.com).

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 840		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 840	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2007 in the Society for the Study of Amphibians and Reptiles are as follows: **REGULAR** membership US$60 (Student $30)—includes *Journal of Herpetology* and *Herpetological Review*; **PLENARY** membership US$80 (Student $45)—includes *JH*, *HR*, and annual subscription to the *Catalogue of American Amphibians and Reptiles*; **INSTITUTIONAL SUBSCRIPTION** $115—includes JH and HR. Additional fee for airmail postage outside USA $35 for one year. Additional membership categories available on the SSAR webpage: http://www.ssarherps.org/pages/membership.html.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

To join SSAR or to renew your membership, please visit the secure online Allen Press website:

Future Annual Meetings

2008 — Montreal, Canada, 23–28 July (with ASIH, HL)
2009 — Portland, Oregon (with ASIH, HL)

About Our Cover: *Adenorhinos barbouri*

The Udzungwa Short-Headed Viper, *Adenorhinos barbouri*, is among the rarest and least known vipers in Africa. Known from only a few localities in the Udzungwa and Ukinga Mountains of southwestern Tanzania, *A. barbouri* was described in 1930 by Arthur Loveridge (Proc. New England Zoöl. Club 11:107–108), who placed it within the genus *Atheris*. It has been seen few times since, and until the discovery of this specimen, had yet to be photographed alive. The snake remains enigmatic—museum specimens number fewer than 25 and several of these were obtained as dead specimens from local farmers or tea estate workers.

After Loveridge formally described the species from localities in the Udzungwas, he reported on a collection of additional material in 1933 (Bull. Mus. Comp. Zoöl., Harvard College 74[7]:195–416), extending the range south to the Ukinga Mountains, which have volcanic origins in the East African Rift rather than the more ancient Eastern Arc orogeny. Remarkably, no specimens of *Adenorhinos* were reported for nearly 50 years following this publication. A few individuals were sporadically collected during the 1980s and 1990s, in large part because of focused efforts to locate the species. Instrumental in these efforts was Jens Rasmussen, the late curator of herpetology at the University of Copenhagen who, along with Kim Howell (University of Dar es Salaam, Tanzania), summarized all known information on *Adenorhinos* in a 1998 paper (Rasmussen and Howell 1998. Afr. J. Herpetol. 47[2]:69–75).

The taxonomy of *Adenorhinos* has fluctuated somewhat over the last 77 years. In his original description, Loveridge placed this snake within *Atheris*, the genus containing the African bush vipers. However, in light of several morphological apomorphies, in particular a unique subcutaneous compound mucus secreting gland, Marx and Rabb (1965. Field. Zool. 44[21]:161–206) elevated the species to its own genus, *Adenorhinos* (adeno = gland, rhinos = nose). *Adenorhinos* is unique in many additional respects as well, and several features led Marx and Rabb to place *Adenorhinos* near the base of the viperine radiation, a hypothesis that was supported by later morphological phylogenies (Groombridge 1986. *In* Z. Rocek [ed.], Studies in Herpetology, pp. 219–222. Proceedings of the Third Ordinary General Meeting of the Societas Europaea Herpetologica, Prague; Ashe and Marx 1988. Field. Zool. [N.S.] 52:1–23). It exhibits a foreshortened snout, a squat, seemingly terrestrial habitus, brown checkered coloration, and an extremely short tail. Hardly resembling the bush vipers at first glance, *Adenorhinos* has several hallmarks of a terrestrial lifestyle.

Nonetheless, affinities with the atherine bush vipers have been strongly supported by a recent molecular study (Lenk et al. 2001. Mol. Phylogen. Evol. 19[1]:94–104). Surprisingly, despite its disparate morphology, analysis of mitochondrial DNA places *Adenorhinos* well within the *Atheris* clade where it is sister to *Atheris ceratophora*, a horned bush viper and another endemic of Tanzania's ancient highland rainforests. If this result is supported by further molecular studies, *Adenorhinos* will represent the evolution of a truly different morphology from within a somewhat more conservative clade of relatives.

PHOTO BY MIKE HETTWER

Luke Mahler is a PhD candidate in the Department of Organismic and Evolutionary Biology at Harvard University. His thesis research investigates the role of ecological factors on rates and patterns of evolution in several families of lizards. Luke encountered this female *Adenorhinos* fortuitously in the Udzungwa Mountains of Tanzania in March 2007. The snake was photographed using a Canon 20D digital camera with a 100mm macro lens (f2.8) and an MT-24EX Twin Lite flash.

NEWSNOTES

USNM Collections Moving

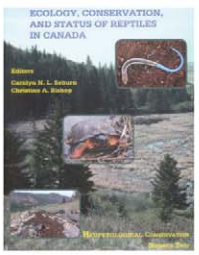
The collections of the Division of Amphibians and Reptiles, National Museum of Natural History (Smithsonian Institution) are scheduled to be moved from the Natural History Building on the National Mall to a new storage wing at the Museum Support Center in Suitland, Maryland beginning about 1 October 2007 and continuing through the first week of April 2008.

It is anticipated that the collection management staff will be devoting significant amounts of time to preparing the collection for the move as well as moving the collection. It is realistic to assume that there will be significant periods of time between now and when the collection move is complete when there will be delays in processing loan requests and times when parts of the collection will not be available for examination by visitors. Visitors in particular should contact us well ahead of their projected visits to assure that collections will be available for their use. The collection will be moved by major taxonomic units. Each unit will be unavailable for study during the time that unit is being moved to the new facility.

Once the move has been completed, we will send out an announcement, including new contact information for the collection management staff as well as appropriate addresses to use for loan returns.

The Use of Amphibians in the Research, Laboratory, or Classroom Setting

The Institute for Laboratory Animal Research announced the publication of *ILAR Journal*'s most recent issue, "Use of Amphibians in the Research, Laboratory, or Classroom Setting" (vol. 48, no. 3). This important issue covers a broad range of topics relevant to research and related work with amphibians, as indicated in the table of contents: Introduction: The Art of Amphibian Science (Stephen A. Smith and Michael K. Stoskopf); Amphibians Used in Research and Teaching (Dorcas P. O'Rourke); Facility Design and Associated Services for the Study of Amphibians (Robert K. Browne, R. Andrew Odum, Timothy Herman, and Kevin Zippel); Amphibian Biology and Husbandry (F. Harvey Pough); Reproduction and Larval Rearing of Amphibians (Robert K. Browne and Kevin Zippel); Diseases of Amphibians (Christine L. Densmore and D. Earl Green); Medicine and Surgery of Amphibians (Edward J. Gentz); Amphibians as Animal Models for Laboratory Research in Physiology (Warren W. Burggren and Stephen Warburton); Amphibians as Models for Studying Environmental Change (William A. Hopkins); IACUC Issues Associated with Amphibian Research (Leanne C. Alworth and Stephen B. Harvey); Amphibian Resources on the Internet (Michael W. Nolan and Stephen A. Smith); Compendium of Drugs and Compounds Used in Amphibians (Stephen A. Smith). To purchase copies of this issue or for more information about the *ILAR Journal*, please visit our website: http://dels.nas.edu/ilar_n/ilarjournal/journal.shtml. In



Society for the Study of Amphibians and Reptiles
New Releases for 2007

Contributions in Herpetology

CONTRIBUTIONS TO THE HISTORY OF HERPETOLOGY VOLUME 2 by Adler, Applegarth, and Altig

The books consists of three sections, each worldwide in coverage. The first and longest section is a series of 285 completely new biographies. The coverage of herpetologists is global and taxonomically diverse. The second section in an index of 3,603 authors in taxonomic herpetology. The third section is a listing of PhD herpetologists and their academic lineages. 400 pp., clothbound. July 2007, in conjunction with 50th Anniversary meeting. ISBN 978–0–916984–71–7 $65.00 (member price until Nov. 2007 $50.00) plus shipping.

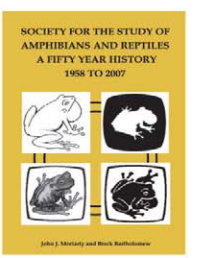
Herpetological Conservation

ECOLOGY, CONSERVATION, AND STATUS OF REPTILES IN CANADA by Seburn and Bishop (eds.)

This volume covers the current view of the status of all 46 species Canadian reptiles and the difficult issues faced in their conservation. Overviews of the ecology and conservation of the major groups (turtles, sea turtles, snakes, and lizards). Published in association with the Canadian Amphibian and Reptile Conservation Network. x + 246 pp., clothbound with a dust-jacket. June 2007. ISBN 978-0-916984-70-0. $40.00 (member price until Nov. 2007 $32.00) plus shipping.

Facsimile Reprints in Herpetology

THE LIFE AND HERPETOLOGICAL CONTRIBUTIONS OF MARIO GIACINTO PERACCA (1861-1923)



Mario Peracca was one of the foremost Italian herpetologists of the late 19th and early 20th centuries. He published numerous faunal works and described 72 species in 64 papers–all of which are reproduced in this facsimile. He was a pioneer of reptile husbandry, keeping a great diversity of species. The book includes an extensive biography, bibliography and synopsis of taxa by Franco Andreone and Elena Gavetti. Published in cooperation with Societas Herpetologica Italica. 570 pp., clothbound. February 2007. ISBN 978-0-916984-69-4. $55.00 plus shipping.

Herpetological Circulars

A REVIEW OF MARKING AND INDIVIDUAL RECOGNITION TECHNIQUES FOR AMPHIBIANS AND REPTILES by Ferner

This circular is a complete revision of Ferner's 1979 Marking Techniques Circular. Techniques covered range from toe clipping, shell notching and paint marking to PIT tagging and radio telemetry. This is the only up-to-date marking manual currently available. A must for any herpetologist or field biologist. iii + 72 pp., February 2007, ISBN 0-916984-68-0 $11.00 plus shipping.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES: A FIFTY YEAR HISTORY: 1958 TO 2007 by Moriarty and Bartholomew

The SSAR History provides highlights of the first 50 years of the Society's existence. This publication includes complete listing of 50–yr, 40+–yr, and 25+–yr members, Society Officers, Publications, Editors, Annual Meetings, and Committee Chairs. The history is illustrated in color with meeting photos and publication covers. A must have for anyone interested in SSAR. iv + 60 pp., July 2007, in conjunction with 50th Anniversary meeting. ISBN 978–0–916984–72–4 $10.00 (member price until Dec. 2007 $7.00) plus shipping.

Send orders to: Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158-0517, USA. **Telephone / fax** 801-562-2660; *email*: ssar@herplit.com. Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may be charged to VISA or MasterCard (Account number and expiration date must be provided). SSAR membership details and a complete list of Society publications can be obtained on request from the Publications Secretary.

addition to the purchase prices for single and multiple issues, the site has a link to sign up to receive the *Journal* regularly. We hope you find this issue useful, interesting, and informative. We welcome your ideas of topics for future issues, as well as submissions for discrete publication in our web-based e-Journal. (Ms.) Cameron H. Fletcher, Managing Editor, *ILAR Journal*, Institute for Laboratory Animal Research (ILAR), The National Academies, 500 Fifth Street NW, Keck 681,Washington, DC 20001, USA. Tel: 202/334-2592; Fax: 202/334-1687; e-mail: cfletcher@nas.edu.

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (rwh13@csufresno.edu) well in advance of the event.

11–14 October 2007—29th Annual Meeting of the Gopher Tortoise Council, Milton, Florida, USA. Information: http://www.gophertortoisecouncil.org/.

2–4 November 2007—34th Annual Meeting, Kansas Herpetological Society, Topeka Zoo, Topeka, Kansas, USA. Information: http://www.cnah.org/khsAnnualMeetingInfo.html.

23–27 June 2008—6th Symposium on Lacertids of the Mediterranean Basin, Lesvos Island, Greece. Information: http://www.gli.cas.cz/seh/news/6th%20Lacertids%20Symposium%20-%20First%20Circular.pdf.

17–22 August 2008—6th World Congress of Herpetology, Manaus, Brazil. Information: www.worldcongressofherpetology.org.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Michele Johnson** or **Josh Hale**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can be found at: http://www.herplit.com/contents.

Influence of Altitude and Topography on Population Structure in Salamanders

Understanding the influence of abiotic factors on the spatial distribution of genetic variation is one of the primary goals of molecular ecology. The authors investigated the effects of altitude and topography on genetic variation in *Ambystoma macrodactylum*, the long-toed salamander, in northwestern Montana. They sampled individuals (N = 549) from 10 low altitude (< 1200 m) and 11 high altitude (> 1200 m) populations and used seven microsatellite loci to genotype each individual. Genetic structure was analyzed using pairwise F_{ST} estimates, population graphing methods and Bayesian analyses of population structure. The authors found that gene flow was limited between high and low altitude populations and among high altitude sites. Results also showed that gene flow was relatively higher among low altitude populations. The authors propose that wide-scale spring flooding may account for the high genetic diversity of low altitude populations by facilitating gene flow among these populations, while harsh habitat and climatic conditions may explain the limited gene flow between high altitude populations. The authors also suggest that different life history characteristics of high and low altitude populations (e.g., clutch size, egg size, time to metamorphosis) may result from divergent selection pressures and could further contribute to the limited gene flow observed between high and low altitude populations.

GIORDANO, A. R., B. J. RIDDENHOUR, AND A. STORFER. 2007. The influence of altitude and topography on genetic structure in the long-toed salamander (*Ambystoma macrodactulym*). Molecular Ecology 16:1625–1637.

Effect of Leaf-Litter Depth on Rainforest Frog Distribution

Anurans are recognized as an important component of leaf-litter communities in tropical forests; however, studies of microhabitat characteristics and their effect on these anurans are limited. To address this, the authors investigated the abundance, distribution and microhabitat of leaf-litter anurans in the Atlantic Rainforest at Ilha Grande, south-eastern Brazil. They conducted nocturnal and diurnal surveys, counting all frogs within 234 2m × 1m plots on the forest floor, and determined the depth, weight and composition of the leaf-litter from each plot. The authors found 185 frogs of eight species, each of which was endemic to the Brazilian Atlantic Rainforest: *Brachycephalus didactylus*, *Dendrophryniscus brevipollicatus*, *Adenomera marmorata*, *Eleutherodactylus binotatus*, *Eleutherodactylus guentheri*, *Eleutherodactylus parvus*, *Zachaenus parvulus*, and *Chiasmocleis* sp. Results indicated that the depth and proportion of leaves in the leaf-litter was positively related to frog abundance and species richness. The authors propose that species richness and abundance are higher in environments with deep leaf-litter because these environments provide a wider range of microhabitats—especially for egg laying, a greater number of refuges against predators, and a higher density of arthropod prey. They also found that while leaf litter depth and leaf composition correspond to higher anuran community diversity, individual species had different responses to local leaf litter conditions.

VAN SLUYS, M., D. VRCIBRADIC, M. A. S. ALVES, H. G. BERGALLO, AND C. F. D. ROCHA. 2007. Ecological parameters of the leaf-litter frog community of an Atlantic Rainforest area at Ilha Grande, Rio de Janeiro state, Brazil. Austral Ecology 32:254–260.

Delaying Parturition in a Viviparous Lizard

The delaying of parturition (i.e., birth) following the completion of embryonic development can be important for maximizing offspring fitness in challenging environmental conditions. This is especially true in ectothermic viviparous species, where the environment experienced by the female during pregnancy can profoundly influence both gestation length and offspring phenotype and fitness. The authors studied populations of the viviparous Snow Skink, *Niveoscincus ocellatus*, at the extremes of their altitudinal range in Tasmania, Australia, by investigating their ability to delay parturition in cold conditions and the fitness consequences for the offspring. Late-term pregnant females from both high (1200 m) and low (50–75 m) elevation sites were maintained in one of four treatments: control conditions in which they could effectively thermoregulate in a thermal gradient ranging 12–35°C (N = 60), or treatments at 10°C with no chance of thermoregulation for one (N = 60), two (N = 40), or three weeks (N = 40). The authors found that females from both the high and low altitude sites were able to delay parturition in cold conditions with no effect on offspring weight at birth, dispersal distance or survivorship after birth, with one exception: females from the high altitude site maintained at 10°C for three weeks were less able to delay parturition and suffered a decrease in offspring viability. The authors propose that while delaying parturition can act to maximize fitness in some conditions, in severe environments, such as those experienced by the high altitude population, the benefits of delayed parturition in response to environmental cues are reduced by the constraints of their short breeding season.

Atkins, N., R. Swain, E. Wapstra, and S. M. Jones. 2007. Late stage deferral of parturition in the viviparous lizard *Niveoscincus ocellatus* (Gray 1845): implications for offspring quality and survival. Biological Journal of the Linnean Society 90:735–746.

Marine Resources Subsidize Diet Of Desert Geckos

The movement of nutrients from aquatic ecosystems to coastal habitats via biotic and abiotic vectors can have a profound influence on terrestrial ecosystems. This is especially true in the Atacama desert in Peru, an arid area of extremely low productivity that faces the Peru-Chile cold current, one of the world's most productive marine ecosystems. To investigate the relationship between marine and terrestrial food webs in the Atacama desert, the authors surveyed populations of terrestrial consumers (i.e., desert invertebrates and geckos) and analyzed stomach contents and stable isotope ratios of carbon ($\delta^{13}C$) and nitrogen ($\delta^{15}N$) from several desert predators, one of which was the Paracas Gecko, *Phyllodactylus angustidigitus* (N = 105). The average number of geckos in near-shore plots was significantly higher than in desert plots situated inland, and the majority of gecko prey items were intertidal invertebrates, although the proportion of intertidal prey items covaried with the geckos' distance to the shore. The $\delta^{13}C$ isotope signatures of geckos was more similar to *Ulva*, a marine algae, than to terrestrial plants, and the $\delta^{15}N$ values suggested that geckos occupy a high trophic level in both the intertidal and desert nocturnal food webs. The authors compare these results to those from other desert predator species, and suggest that a lack of rainfall in the Atacama desert promotes a reliance on marine resources in these geckos and other desert species, which as a consequence, are more affected by variability in marine productivity than patterns of terrestrial plant growth.

Catenazzi, A., and M. A. Donnelly. 2007. The *Ulva* connection: marine algae subsidize terrestrial predators in coastal Peru. Oikos 116:75–86.

Potential Impacts of Climate Change on Marine Turtles

Climate change has the potential to affect the ecology, phenology and survival of many species, particularly thermally sensitive species. In the Loggerhead Seaturtle, *Caretta caretta*, sex is determined by temperature in the middle third of incubation. Female offspring result from high, and male offspring from relatively low, temperatures. To investigate potential affects of climate change on this species, the authors compiled 26 years of nesting site data from North Carolina, the northernmost nesting site for this species in the United States, with local climate data. They used these data to predict current sex ratios and to model possible changes under different climate change scenarios. Currently, North Carolina nesting sites produce proportionally more males than nests further south in Florida, which has the majority of nesting sites in the United States but produces less than 10% males. The results of their model show that a 2°C increase in air temperature would likely lead to the complete feminization of the primary sex ratios in Florida, and with a 3°C increase, incubation temperature would be above lethal. In contrast, the model shows that on North Carolina beaches, turtles need only shift temporal distribution of nesting by one week to adapt to a 3°C increase in air temperature. The authors highlight the importance of preserving the disproportionately significant male-producing beaches, especially those beaches that may be shielded from future climate change.

Geckos in Termitaria

Gymnodactylus carvalhoi, a gecko species found in the Brazilian Cerrado, appears to be entirely restricted to termitaria (i.e., termite nests), but reasons for this habitat specialization remain unknown. The authors tested three, non-exclusive hypotheses to explain this specialization, including: to avoid thermal extremes, to avoid predators, or to take advantage of abundant food. First, the authors used drift nets and pit traps to confirm that these geckos are restricted to termitaria, most likely only leaving to find new nests. The authors used data loggers to monitor temperature within and on the surface of four termitaria every 10 mins for 13 days. To assess the effect of predators on this population, and to determine diet, geckos were collected and examined for tail loss (N = 69), and stomach contents were analyzed (N = 60). Results showed that temperature remained relatively constant within the temitaria, buffering these geckos against external temperature extremes. Stomach content analysis revealed that termites are abundant and comprise the vast majority of the geckos' diet (92% of prey by number, 77% by volume). The authors suggest that the high frequency of tail loss indicates that predator avoidance is not an important factor. The authors concluded that a combination of thermal constraints, a paucity of other suitable refuges, and diet preferences explain the restriction of these geckos to termitaria in the Brazilian Cerrado.

Chemicals Signal Status in Male Iberian Rock Lizards

Conspicuous badges of status play an important role in male competition in many species, preventing potentially costly fights by signaling fighting ability or dominance. Most previous studies have concentrated on visual or acoustic signals; however, it is increasingly being recognized that chemical signals can also indicate male status. To examine this, the authors determined whether chemicals in femoral gland excretions signaled dominance status in male Iberian rock lizards, *Lacerta monticola monticola*. The authors staged encounters between pairs of males (N = 30 males) to establish which individuals were dominant, while controlling for body size. Femoral secretions were collected from each male and analyzed with a gas chromatograph-mass spectrometer. A phytohaemagglutinin injection test was used to assess immune response from each lizard. Finally, behavioral responses to different components of the femoral gland secretions were also measured. Results were analyzed using both Principal Component Analysis and ANOVA. Dominant males had high levels of hexadecanol in their femoral gland secretions, a substance which was also shown to elicit aggressive behavior in males. Further, male immune response was correlated with the abundance of hexadecanol in the femoral gland secretions. The authors suggested that, because of its correlation with immune responses and the aggressive behavior it elicits in conspecifics, the hexadeconol content of femoral gland secretions may provide a reliable signal of male dominance and status in the Iberian Rock Lizard.

Timberland Rattlesnakes Use Public Information to Assess Foraging Locations

Animals generally make foraging decisions based on an integration of information from their own experience and from monitoring other foraging animals. The use of public information to make decisions about resource quality has been well studied in animals that live in groups, however, its importance for solitary animals is unknown. To address this, the author conducted choice experiments to determine whether public information, in this case chemical cues, inform foraging decisions in the timber rattlesnake, *Crotalus horridus*. All experiments were performed using 16 captive-born snakes. In the first experiment, snakes were given the choice between an arm of a T-maze containing chemical cues from a conspecific, and another arm with no cues. In the second, one arm of the T-maze contained the chemical cue of a fed, and the other of an unfed, conspecific. Finally, a third experiment, an arena trial, was designed to measure the amount of time spent in an ambush coil in areas previously occupied by fed or unfed conspecifics. Results revealed that snakes were more likely to choose the arm of the T-maze that contained the chemical cue of a conspecific over an untouched arm, but they did not distinguish between fed and unfed conspecifics. However, the results of the third choice trial showed that snakes spent more time in an ambush coil in areas previously occupied by fed than unfed individuals. The author concludes that public information may be a more important factor informing foraging decisions in solitary animals than previously thought.

CLARK, R. W. 2007. Public Information for solitary foragers: timber rattlesnakes use conspecific chemical cues to select ambush sites. Behavioral Ecology 18:487–490.

Multiple Stressors and Frog Declines

Worldwide, more than 40% of the 6000+ described amphibian species have undergone alarming declines, with a number of studies having examined potential causing factors. However, the majority of these studies have concentrated on single stressors, which may mistakenly inflate the importance of a particular stressor in the decline. To address these concerns, the authors investigated the effect of two stressors, pesticides and introduced fish, on the

Mountain Yellow-legged Frog, *Rana muscosa*. Each lake, pond, and marsh encountered in the central southern Sierra Nevada of California (N = 6831 waterbodies) was categorized for frog and fish presence, and the surrounding habitat was surveyed and upwind pesticide use estimated. Results from multivariate generalized additive models suggested that while frog presence was influenced by multiple stressors, pesticide use contributed substantially more to frog presence or absence than introduced fish. Further, the topography of the waterbodies themselves was important, with sheltered waterbodies far more likely to have frogs, despite the presence of pesticide use. The authors suggest that windborne pesticides may be a crucial factor in amphibian declines, even in pristine locations, especially as pesticide exposure weakens immune responses in amphibians and increases susceptibility to disease. Finally, the authors emphasize the importance of investigating multi-factor causes in amphibian decline research.

DAVIDSON, C. AND R. A. KNAPP. 2007. Multiple stressors and amphibian declines: dual impacts of pesticides and fish on yellow-legged frogs. Ecological Applications 17:587–597.

Lizard Pollinator Mediates Positive Interactions Between Plant Species

Previous studies of indirect relationships between species have focused primarily on predator-prey and competitive interactions. However, indirect interactions can also be an important factor in mutualistic relationships. In this study, the authors tested whether the declining, endemic *Trochetia blackburniana* plant benefits from proximity to the endemic *Pandanus* plant in Le Pétrin, Mauritius. This positive interaction is thought to be mediated by the blue-tailed day gecko, *Phelsuma cepediana*, which moves between *Pandanus* thickets, the gecko's preferred microhabitat, and *T. blackburniana*, where it feeds on nectar and pollinates the plants. By comparing *T. blackburniana* plants growing close to (< 10 m) with those growing away from *Pandanus* (> 20 m), the authors confirmed that gecko visitation to *T. blackburniana* was related to its proximity to *Pandamus* plants. Also, by fitting a generalized linear mixed-model, the authors demonstrated that the number of fertilized fruits on the *T. blackburniana* plants was also positively related to proximity to *Pandamus* thickets, but results from a previous study show that these differences are unrelated to variation in soil quality. Finally, an experiment was conducted in which geckos were excluded from some *T. blackburniana* branches. This resulted in fewer fertilized fruits relative to branches on the same plant from which geckos were not excluded. The authors highlight the importance of considering these types of indirect, positive interactions in both plant and lizard conservation.

A major challenge presented itself to zoo herpetologists since World War II: how could they become important players in a world of shrinking biodiversity and maximize the use of their collections? It is beyond the scope of this paper to provide specific details but what happened at the Smithsonian's National Zoological Park (NZP) over 75 years may mirror, in part, what happened at other zoo herp departments and at other zoos throughout the world and provide clues as to the substantial change during this period.

FACILITIES

"This building promises to be one of the finest of its kind in the world."

—William M. Mann in *1930 Smithsonian Annual Report, 100*

"The content of the art fulfills two roles; identifying the building as a reptile house, and artistically displaying the evolutionary history of reptiles. The large mosaic stegosaurus over the entrance connects present day reptiles to their larger ancestors. Pterodactyls clutching the corners of the portico ready to spring off into flight hint at the ancestral connection between birds and reptiles. The ten panels on the doors alternately display a lumbering stegosaurus and battling yin-yang lizards. Much like religious stained glass, the art is used in the traditional role as a means to communicate. A simple message is conveyed: 'these animals are all related, and here are some of their ancestors.'. . . The art enriches the experience of the building: yielding pleasure and education, two of the founding directives of the zoo."

—Gavin Farrell in *Smithsonian Institution National Zoological Park: A Historic Research Analysis* in 2004.

William M. Mann, Director of the National Zoological Park (NZP), and municipal architect Albert L. Harris traveled to Europe in the spring of 1929 to evaluate zoo reptile buildings to use as models for the new one being planned at NZP. Mann's vision was to construct a facility second to none by using artwork and architectural ornamentation prominently to place the visitor in a beautiful setting immersed in animal imagery. Only two years later, the National Zoo's Reptile House was opened to the public and

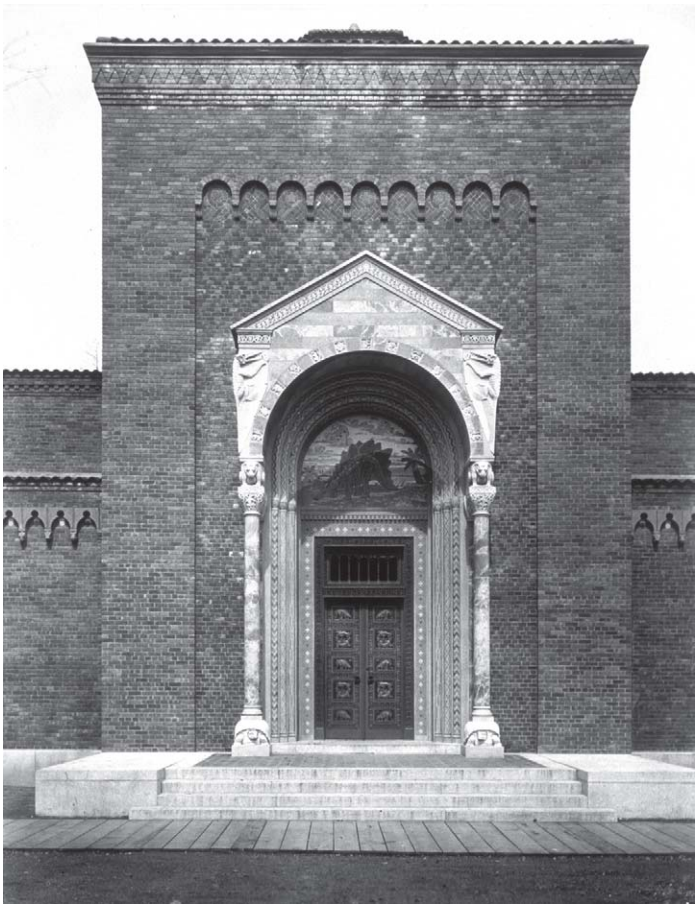

FIG. 1. Photograph of Reptile Building at National Zoological Park shortly after completion in 1931. Credit: National Zoological Park Photo Archives.

this impressive building remains one of the most beautiful reptile facilities in the world (Figs. 1–4). Ewing (1990) published a report called "An Architectural History of the National Zoological Park." According to Ewing, the architecture exemplifies the Italian Byzanto-Romanesque ecclesiastical style and the main cathedrals in Ancona and Verona, built in Romanesque style in Northern Italy, provided the idea for Harris' design. ". . . The brick structure was assembled in a building-block fashion, accumulating to form several ranges. Rising from a low asymmetrical level, the tower culminated in an octagonal drum and lantern . . . articulated with round windows encircled by alternating red and white marble blocks . . . the arch of the pedimented porch displayed small alternating curved blocks of little creatures: toads, turtles, lizards, etc. Under the cornice along the entire facade the arched corbels culminated in roughly-hewn abstracted reptiles. These terracotta figures served as subtle gargoyles, continuing the correlations with the cathedral model." Unfortunately, the original elevated porch leading to the entrance has been removed but the porch columns supported by turtles remain. The massive wooden entrance doors with essonite/gold leaf panels depicting many extinct and extant

FIG. 4. Carved rock tortoise supporting column at entrance to reptile building at Smithsonian Institution's National Zoological Park. Credit: photograph by Dennis Desmond in 2004.

reptiles have been moved to an interior space; the original bronze door pulls with two entwined serpents have been replaced. A secondary entrance shows two dragon-like reptiles facing each other under a rounded arch of molded bricks.

The renowned artist and sculptor John Joseph Earley[1], known for his remarkable creations of concrete mosaics and figures, in part fashioned the façade which abounds with stylized reptiles and amphibians—*Stegosaurus* over the entrance and crocodiles as decorative figures (Fig. 3), turtles supporting columns (Fig. 4), toady creatures peering down from the top of the archway, and an array of turtles, toads, and lizards scattered near the roof and around the building. The colored concrete door molding was fashioned by Earley, and the dinosaur mosaic in the transom was by artist Charles R. Knight. All of the larger exhibits within the building had background murals painted by Knight. These were detailed paintings of ancient ruins, such as Egyptian temples, as well as natural habitat scenes. Unfortunately, all of these murals were either painted over or the exhibits were totally destroyed and rebuilt during the middle 1950s and into the early 1960s. Even with these changes, this wonderful building is a spectacular edifice which probably could not be duplicated today because of cost and lack of skilled artisans. It must be said, however, that many modern reptile buildings are impressive structures with splendid exhibits[2].

The basement served as a commissary and butcher shop for animal feed (pictured in Conant 1980). In the early 1980s, the interior of the building was remodeled, exhibits were improved, and an acoustical ceiling was added to reduce noise in the visitor area. Added outside the building in 1980–1981 was a series of three small exhibits constructed of concrete masonry (and a wooden walkway) and four outdoor displays containing pools which now hold crocodilians and Komodo Dragons. The central basement interior area was re-worked into an invertebrate exhibit in 1986, and a walk-through greenhouse with butterflies and hummingbirds was added five years later. During the past few years, the exterior of the building has been cleaned, the roof has been repaired, the original skylights replaced, and the interior walls re-plastered and re-painted.

In 1984, a family learning center called HERPlab was installed in the building. There, docents and zoo staff interact with zoo visitors by describing amphibian and reptile biology, answering questions and leading tours. Curator Dale Marcellini and herpetologist Thomas Jenssen observed visitor behavior in the National Zoo's Reptile House and discovered that zoo visitors spend an astonishingly brief time viewing exhibits, averaging only ca. 8 sec per stop (Marcellini and Jenssen 1988). Based on this disturbing finding, a stronger emphasis on interactive education was developed by opening the Reptile Discovery Center, supported by a grant from the National Science Foundation. This unique exhibit approach incorporated some of the aspects of HERPlab but added a series of interesting modules and displays throughout the building addressing other features of amphibians and reptiles. One important element of the approach was the use of polling/survey data derived from visitors to quantitatively assess the effectiveness of this exhibit. Doering (1994:viii) stated that the modules had significant effects on visitors: "*Behaviorally*, the interactive stations slowed persons down, made them more attentive, and lengthened their time in the exhibit. *Emotionally*, the modules improved visitors' feelings about reptiles. *Intellectually*, they communicated new ideas, especially about internal anatomy, communication, and feeding."

During the past seventy-five years, reptile buildings and accompanying exhibits throughout the world were often designed by architects and zoo administrators who had little experience with living herps, public education, or who paid scant attention to the concept of exciting and aesthetically-pleasing presentations. Educational and interactive exhibits were an afterthought; visitors were subjected to row after row of uninspiring and unimaginative displays, hardly an enriching experience. One problem was the lack of input from the biological staff. Until the 1960s, amphibians and reptiles were rarely kept in appropriate social situations and little attention was paid to behavioral or environmental cues; social stressors among conspecifics such as competition or aggression were barely considered. Fortunately, zoo biologists have now become aware of these deficiencies and have worked to remedy them.

History of the Collection

In the late 1920s and early 1930s, a number of interesting herps were represented in the NZP collection: Komodo Dragons[3], Sumatran Cobras, King Cobras, Boa Constrictors, Gila Monsters and Beaded Lizards, Zaire Toads, many rattlesnakes, Radiated Tortoises, Gould's Monitor, and other lizards. In the Annual Reports of NZP beginning in 1931, one can see the enormous variety of specimens in the collection, such as tuataras.

The Zoo collection was utilized in 1932 for a classic scientific study on brooding behavior in pythons by Frances G. Benedict, Director of the Nutrition Laboratory at the Carnegie Institution of Washington. He observed an incubating female African Rock Python (*Python sebae*) on exhibit and made detailed environmental and body temperature readings during one entire day.

Captive crocodilians can be exceedingly dangerous, especially if their exhibits are poorly designed without shift cages[4]. In the late 1950s, the solarium housed a Nile Crocodile (*Crocodylus niloticus*) and an American Crocodile (*Crocodylus acutus*) in the same enclosure. The middle enclosure housed an aggressive and agile[5] Saltwater Crocodile (*Crocodylus porosus*) called "Biggie" by the staff, and the end enclosure featured a group of 5–7 foot long American Alligators (*Alligator mississippiensis*). Because there were no shift cages, keepers had to work around the crocodilians. The Nile and American crocodiles were extremely aggressive, attacking the keepers constantly. Two keepers were always in attendance, one to clean and the other to fend off the reptiles. Holding them off with a broom and shovel worked for the most part but cleaning these enclosures was a constant strain on the staff.

"Biggie" was acquired in the 1930s and lived over 40 years at the zoo where it attained a length of over 14 feet. When the crocodilian was weighed and measured in 1932, its size was modest: 150 lbs and six feet total length. One of us (WAX) was responsible for cleaning its enclosure during the late 1950s and early 1960s, a very dangerous task indeed, for the procedure was to actually enter its domain. On one occasion, "Biggie" was lying in the emptied pool and WAX was on the surrounding land, picking up some leaves. "Biggie" spun around and charged with mouth agape and WAX had to leap over the recurved bars. Unfortunately,

FIG. 5. Adult male Cayman Island blue iguana (*Cyclura nubila lewisi*) on exhibit at Smithsonian National Zoological Park in 2003. Described in 1940, the lizard was widely distributed in dry habitats over most of the island but is now restricted to a few remnant populations, due to human influences. In 2005, the population crashed precipitously; now only 15–25 lizards are left. Credit: photograph by Jessie Cohen, Smithsonian National Zoological Park.

the cuff on his pants was caught on one of the pointed tips. As WAX tried to free his cuff while balanced on the top of the bars, his hand fell off to one side. The reptile redirected the attack toward the dangling hand rather than the foot and just missed a tasty snack when WAX was able to pull his hand away, extricate his leg from the bars, and fall into the next enclosure.

At NZP, live food was used until the 1960s[6]. When one of the keepers was seen by a mother and child carrying a rabbit in a wicker basket, the child recognized his pet "Fluffy," donated just minutes before to the zoo. When the child asked where the keeper was taking his rabbit, the latter said, "I am going to feed him to the python" and continued on to finish his task. His horrified parents wrote a seething letter to Director Theodore H. Reed, who immediately banned the use of live food during public hours. Although offering dead prey is now common in zoos, some reptile buildings remain closed during feeding, due to concern about public sensitivities. NZP feeds only dead vertebrate prey and stays open.

Many years ago, NZP herp keepers also fed dead animals from the collection to reptiles. Head keeper Lee Schmeltz acquired a carcass of a muntjac that recently died in the collection and fed it to the Komodo Dragon. The dragon seized the muntjac by the belly and tossed its head in a violent slashing motion which eviscerated the deer, and splashed the glass front of the enclosure. Someone reported the incident to higher authorities and Schmeltz was warned never to let it happen again (C. Wemmer, pers. comm.).

NZP is the national zoo of the United States, so governmental employees, Smithsonian scientists, and military personnel, particularly the Naval Medical Research Unit-S.E. Asia (NAMRU) and the Army Medical Research Unit-North Africa (AMRU), often sent amphibians and reptiles to the Zoo. During the 1960s, unannounced large shipments regularly arrived at the local airport, such as one sent by Wesley Dickinson from India (see Murphy and Jacques 2006). The animals in these shipments were mostly unidentified, some venomous, often loose in the box or with their cloth bags unmarked; unpacking these shipments, although exciting, could also be hazardous. Many of the venomous species, such as sea snakes (*Laticauda*), King Cobras (*Ophiophagus*), Indian Cobras (*Naja naja*), kraits (*Bungarus*), Asian coralsnakes (*Calliophis*, *Maticora*), bamboo vipers (*Trimeresurus*), Hundred-Pace Vipers (*Deinagkistrodon acutus*), and saw-scaled vipers (*Echis*) were new to the collection.

On Easter Sunday in 1983, a teenaged boy who liked snakes waited until the building closed, broke the glass of the Gaboon Viper (*Bitis gabonica*) exhibit, put two adult snakes into a plastic garbage bag, flung the bag over his shoulder and caught a bus to take them home. He was bitten through the bag on the shoulder while departing the bus and rushed to the hospital. He survived the ordeal after antivenin therapy was undertaken but recovery was protracted. Later, some well-meaning citizens, including Smithsonian Secretary S. Dillon Ripley's wife, suggested that he be hired at the Zoo since he liked snakes but this recommendation was not adopted. Several others sent get-well cards to Mr. and Mrs. Gaboon Viper.

Play behavior in reptiles is rarely reported. At NZP, an adult Nile Softshell Turtle (*Trionyx triunguis*) collected by William Mann in Liberia, played with a variety of objects: pushing a basketball with its snout, swimming through a hoop, and biting and pulling a hose (Burghardt et al. 1996). One of the captive-hatched Komodo Dragons (*Varanus komodoensis*) named Kraken interacted in the most unexpected way with humans and objects (see Burghardt et al. 2002; Murphy and Walsh 2006 for details).

When we entered the zoo profession (WAX in the late-1950s, JBM in the mid-1960s), there was little discussion in zoos about wildlife conservation. Most efforts centered on keeping amphibians and reptiles alive and plans to accumulate breeding groups were rarely considered. We could not sex our animals accurately and if successful reproduction occurred, it was a major event. Virtually all zoo collections at that time were composed of herps from the wild; captive-bred amphibians and reptiles were mostly unavailable. Now that captive breeding has been relatively successful (although long-term breeding programs producing multiple generations are still somewhat rare), zoos tend to get their new ani-

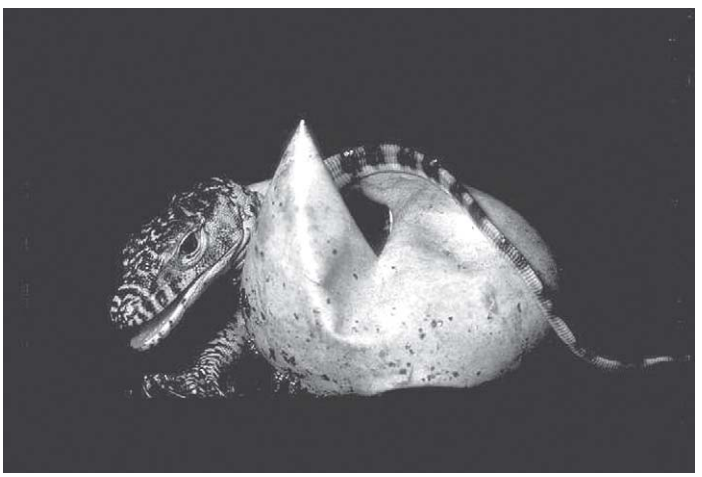

FIG. 6. Komodo dragon (*Varanus komodoensis*) female named "Kraken," hatched in 1992 at Smithsonian National Zoological Park. Credit:
photograph by Jessie Cohen, Smithsonian National Zoological Park.

mals from other zoos rather than the wild. Today there are many cooperative breeding programs in zoos. The downside of these collaborative programs is that we now rarely see something new in zoos; there is not room or resources for a diverse collection with many new species.

Today, the NZP collection is stable, many of the specimens bred in captivity, with ca. 63 species of reptiles totaling nearly 350 specimens and 15 species of amphibians numbering nearly 140 animals. The collection includes Cuban Crocodiles, Gharials, highly-endangered Cayman Island Iguanas (Fig. 5), Aldabran and Radiated Tortoises, an adult Japanese Giant Salamander, large constrictors and a variety of amphibians such as breeding colonies of a number of poison dart frogs (*Dendrobates*) and Panamanian Golden Frogs (*Atelopus zeteki*). Komodo Dragons reproduced at NZP in 1992 for the first time in any zoo in the Western Hemisphere (Fig. 6). Reproduction over multiple generations has been accomplished in several taxa: Emerald Tree Boas (*Corallus canina*), Green Tree Pythons (*Morelia viridis*), Brazilian Rainbow Boas (*Epicrates cenchria*), African Rufous-beaked Snake (*Rhamphiophis oxyrhynchus rostratus*), Chinese Water Dragons (*Physignathus cocincinus*), and Madagascan Giant Day Geckos (*Phelsuma madagascariensis*).

People

Like a notorious keeper at London a century earlier[7], WAX and a fellow keeper at NZP held contests to see who could handle pitvipers (rattlesnakes, copperheads, moccasins, bamboo vipers) without getting bitten. Their reasoning, hardly justifiable and certainly illogical, was this practice was acceptable as a displacement activity to relieve the stress of battling crocodilians. The snakes chosen to be handled all resided on the same row of exhibit cages. Each day before the building opened, these foolhardy caretakers would take turns, starting at the first exhibit cage and working their way down the line. The process was simple: when the serpent was in a resting coil, the contestants would slide hands beneath the coils, lift gently from the substrate for a few seconds, then replace the reptile in its original resting place. The contest ended after the entire group of exhibits holding venomous snakes was sampled or one of the participants lost courage. Miraculously, no one was bitten so none of the snakebite recommendations in Footnote #7 could be tried but had this practice been discovered by their bosses, repercussions would have probably been more unpleasant than a bite.

Over the years, Roy Jennier, Charlie Braxton, Jack Armstrong, Lester Ratliff, Lee Schmeltz, Cecelia Chang, Russell Morrison, Mike Johnson, William Xanten, Sam Davis, Bob Davis, Tom Keefer, Roger Rosscoe, Charles Coutris, Rob Lewis, and David Kessler worked as keepers in the department. The first woman keeper ever hired at NZP was Brenda Hall in the early 1970s, who wrote a paper on tegu lizards (*Tupinambis teguixin*). Today, women outnumber men in the Animal Department. Before curatorial positions were established at NZP, Mario (Jack) DePrato was the Head Keeper. Now retired, the first herpetological curator was Jaren Horsley, who was elevated to General Curator (Fig. 7). His replacement was Dale Marcellini, whose research interests were primarily directed toward public education and visitor behavior, as well as gekkonid and iguanid ethology (Fig. 8). Louis (Trooper) Walsh retired from the zoo as Biologist/Museum Specialist and is best known for his work with Komodo Dragons and boid snakes. Biologist Béla Demeter published a number of papers on Malagasy geckos. Michael Davenport is the current curator who focuses on the captive breeding of crocodilians. In addition to Davenport and Demeter, the current staff is Janis Gerrits, Sean Henderson, and Robin Saunders. After retiring from the Dallas Zoo, one of us (JBM) is now a research associate at the Zoo.

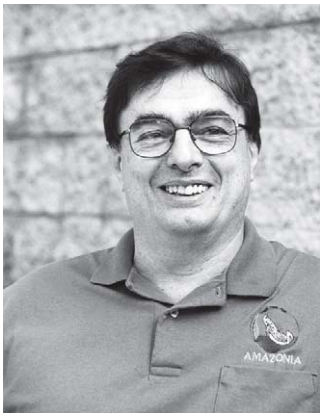

Fig. 7. Retirement photograph of Jaren Horsley in 1996. Credit: photograph by Jessie Cohen, Smithsonian National Zoological Park.

Jonathan Ballou is the Population Manager at NZP's Department of Conservation Biology; he has published many papers and several books on the proper management of captive populations.

Long-term investigation of essential dietary ingredients for captive and wild reptiles by Mary Allen and Olav Oftedal includes evaluating the diets of desert tortoises. The evolution, expansion and sophistication of herpetological medicine and the understanding of emergent diseases has contributed to significant advances. Recently, the pathogenic chytrid fungus attacking captive and wild amphibians was isolated and described by former NZP pathologist Donald Nichols.

John (Jack) Frazier has studied chelonians since 1979 as a Smithsonian research associate. His major focus centers on the conservation of marine turtles and he has published widely in this area. In addition, his earlier studies have included behavioral and ecological aspects of the Aldabran Tortoise and the Star Tortoise, and recently a sortie into nomenclatural never-never land (see Frazier 2006).

The Smithsonian Institution offers stipends for limited periods to outside investigators, mostly from the academic community, to do research at the Zoo. Using this program, Marcellini brought in an impressive series of herpetologists. Eliezer Frankenberg (The Hebrew University of Jerusalem) focused on animal communication, lizard ecology, and reproductive biology. Thomas Jenssen (Virginia Polytechnic Institute and State University) studied lizard ethology and visitor behavior, beginning in the 1980s. Paul Weldon (Texas A & M University) was a research associate at the Zoo from January 1991 to January 1993, working closely with zoo personnel on a variety of studies, such as collecting and analyzing glandular materials from reptiles in zoos. Now living in Baltimore, he currently

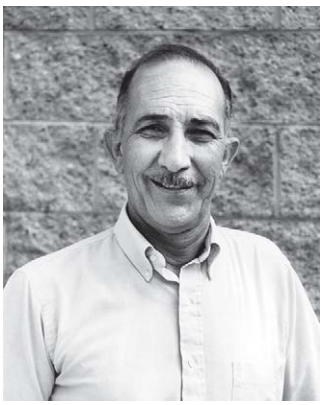

Fig. 8. Retirement photograph of Dale Marcellini in 1996. Credit: photograph by Jessie Cohen, Smithsonian National Zoological Park.

holds the same appointment at the Zoo's Conservation and Research Center in Front Royal, Virginia. Eric Wikramanayake from Sri Lanka was a research associate at the Zoo, specializing in field studies on varanid lizards. He is now a senior conservation biologist for World Wildlife Fund-US in Southeast Asia.

Programs

Christen Wemmer, retired Director of the NZP Conservation and Research Center (CRC) in Front Royal, Virginia, and his associates were instrumental in creating Zoo Biology Training Courses held in many developing countries throughout the world (see Wemmer et al. 1990 for description). The program and all written materials were developed by the staff at the Zoo, beginning in 1987. These courses included a herpetological component and focused on captive management. Zoo herpetologists, including JBM, were participants in these various training courses. In 1997, Wemmer, George Zug from the US National Museum of Natural History, and JBM traveled to Myanmar (Burma) to teach a workshop on herpetology to local wildlife biologists. The course provided an introductory treatment of amphibian and reptile biology, including a field component for sampling populations. This herpetofaunal survey continues to this day.

The American Association of Zoos and Aquariums hosted a Wildlife Conservation and Management Committee (WCMC) workshop on the conservation and captive management of Komodo Dragons, held at Tamin Safari in Bogor, Indonesia in 1995, which included a presentation by Trooper Walsh on the husbandry of these lizards. Three years later, the Thoiry Komodo Dragon Symposium was held at the Thoiry Zoological Park in France. The program was created by Walsh and Colomba de La Panouse, who invited the world's leading experts involved with field research and conservation, laboratory studies, and zoo conservation/education initiatives, to present their findings and write chapters for a comprehensive book on dragons. The research presented by several of the attendees was supported financially by grants from NZP's "Komodo Dragon Conservation Fund." Four years later, the book entitled *Komodo Dragons: Biology and Conservation* appeared.

There have been several herp initiatives at CRC: metapopulation analysis of the Eastern Newt (*Notophthalmus viridescens*) in northern Virginia, including sampling the CRC population; drift fence survey of indigenous species; Box Turtle (*Terrapene carolina*) study; and northern Virginia frog study guide written by Joseph Mitchell for the education program at CRC.

In the reptile building, several dozen volunteers serve as instructors, teaching zoo visitors about amphibians and reptiles. As an example, these interpreters explained the research that was being done on play behavior in Komodo Dragons.

Summary

Retired curator Dale Marcellini (1994) summarized the challenges that zoo herpetologists face when managing zoo collections, "Conservation is one of the main goals of zoo reptile houses, and yet curators act in ways which may be harmful to the conservation of species in the wild. Collections are composed largely of exotic, rare, and wild-caught species. Only rarely are breeding programs done on a long-term basis. When breeding is successful, reintroduction into the wild is almost never done. Zoo herpetologists must begin to act more responsibly in the way collections are managed, and more emphasis needs to be placed on conservation education."

In the same volume, Robert J. Wiese and Michael Hutchins (1994) enumerate additional responsibilities, "There is much work to be done if we are to assist even a fraction of the species currently at risk. Through the successful use of captive-breeding and reintroduction programs in conjunction with strategic collection planning, scientific research, in situ conservation efforts, and public education, professionally managed zoos and aquariums can play a significant role in amphibian and reptilian conservation."

In our view, the results have been mixed! On the plus side, the dramatic improvements of husbandry protocols have led to better lives for captive herps—no longer are "snake dens" ordered every year from suppliers to replace losses as was the case occasionally in the past. Zoos and aquariums are involved in many *in situ* and *ex situ* conservation projects. We are concerned, however, that herpetological collections and buildings are viewed as a relict from the past[8]; as a result, there has been a significant decline in new facilities, emphasis, and financial support. Instead, many zoo administrators build elaborate and costly zoogeographic mixed exhibits housing mostly mammals and birds.

One can track the paradigm shift over seventy-five years at NZP in the literature citations below as the staff gradually became more aware of the enormity of the threat to a diverse and interesting natural world, and began taking steps to intervene by adjusting their programs and research focus.

Acknowledgments.—We dedicate this contribution to veterinarian and retired NZP director Theodore H. Reed, who was at the helm from 1956 until 1983. Reed inherited a facility where major building construction and preventive maintenance had been halted for over twenty years due to inadequate funding. Under his leadership, NZP was reborn with increased appropriations, construction of a number of new buildings and revitalized exhibits. He established the first education department in a zoo in the United States and created the first research positions (Department of Zoological Research) with the hiring of the late John Eisenberg. The acquisition of the Conservation and Research Center (CRC) in Front Royal, Virginia, comprising more than 1200 hectares, was the culmination of a dream and years of intense work by Dr. Reed and Assistant Director John Perry.

Ben Beck, Judith Block, Béla Demeter, Jack Frazier, Devra Kleiman, Karl Kranz, Dale Marcellini, Robin Saunders, Trooper Walsh, Christen Wemmer, and Judy White read early drafts of the manuscript and made helpful suggestions. We thank Ed Bronikowski, Jessie Cohen, Michael Davenport, Dennis Desmond, Jack Grisham, Polly Lasker, Steven Monfort, John Moriarty, Mandy Murphy, J'nie Woosley, and William Xanten III for various courtesies.

Footnotes

[1] "John Earley was the last of the concrete pioneers. Others before him had discovered how to produce the 'magic powder' — portland cement — how to mix it with stone and sand to make concrete, and how to use concrete as a structural material. But Earley was the first to control the exterior appearance of concrete in an important way and to impart brilliant permanent color to the surface. His contribution was unique: he was the man who made concrete beautiful."
Frederick W. Cron in *The man who made concrete beautiful: A biography of John Joseph Earley* in 1977

[2] "One of the most interesting and one of the most fascinating additions of recent years to zoological exhibits is the modern reptile house. Both the animal and the vegetable world are represented in it. It is a whole world of forests, dusky swamps, barren deserts, and tangled jungles brought from North and South and East and West and crowded under one roof. And under the roof, caged among giant palms, hanging bushrope, and drooping resurrection ferns, there squirm and coil the most mysterious and uncanny and merciless of all of God's creatures, housed according to the most advanced ideas of animal science, with all the surroundings peculiar to the wild and natural state of each. This novelty of showing the animals, and the modern facilities for feeding them as once they fed themselves, for studying reptile diseases, and even for operating with the surgeon's knife, have practically revolutionized the snake house of old into the marvelous reptile house of to-day."
—A. W. Rolker in *Treasury of Snake Lore* (1956)

[3] In the paper files on Komodo Dragons in the Reptile House there is an interesting entry attributed to Raymond L. Ditmars. Back in ~1934 when the first dragon arrived at NZP Ditmars was contacted and asked what he thought the lizards would eat and how often they should be fed. He replied, "Offer lobster, fish, octopus, horse meat, cattle organs, fresh killed rats and mice, deer meat, and pig . . . offered three times a day." It is fascinating that the then "world authority" on reptiles would provide such guess work about how much food was appropriate, showing how little was really known about the biology of these animals at the time.

[4] Raymond L. Ditmars (1933) described crocodilians in this way: "Such is the average crocodile—an active, vicious and, above all, treacherous brute. When the keepers of the reptile house in the New York Zoological Park clean out the big pool for crocodilians, they actually walk over the backs of some of the big 'gators, so tame are these. They never become unduly familiar with the crocodiles, finding it necessary to pen the latter behind heavy barred gates—and in the process the men are often chased from the enclosure."

[5] Saltwater Crocodiles have acute vision. At Zoo Atlanta, a large individual located and consumed mealworms tossed into its pool. At NZP, a mixed exhibit of birds and crocodilians was attempted. A large Asian jay was released into the solarium where it flew several times from one end to the other. When it passed overhead on its final journey, "Biggie" exploded from the water and caught the bird in mid-air—over a meter above the surface.

[6] The feeding of live food to snakes has always been controversial among some sectors of the public. It was an issue so inflammatory in London over a century ago that it was discussed in Parliament. For many years, live mice, rabbits, birds, frogs and other prey had been fed to snakes at the London Zoo but little public outcry ensued; in fact, the feeding demonstrations were enthusiastically viewed by the visitors. In 1869, however, the climate began to change, fueled in part by newspaper campaigns in London to elicit reader responses as to whether the practice should continue. A few selected sentences quoted in Blunt (1976) should put the controversy in proper perspective:". . . that a rabbit should be shut up in a cage with a snake without any chance of his life, deprived of the means of escape allotted to him by nature, and subject to the exquisite torture of terror prolonged by factitious circumstances and enhanced by despair" or ". . . trembling rabbits devoured by a serpent?-a monster reptile maintained and thus feasted for the pleasure of the English—for their children . . ." To deal with continuing public pressure, P. Chalmers Mitchell, Secretary of the Society from 1902 to 1935, and curator of mammals Reginald I. Pocock presented dead prey to snakes at the Zoo to determine whether this practice was a viable alternative. They documented (Proc. Zool. Soc. London 1907:785–794) that dead prey would be taken by many different species and would often be ingested at night. A subsequent study on the acceptance of dead prey by

snakes was undertaken by curator Edward George Boulenger in 1915 (Proc. Zool. Soc. London 1915:583–587). The situation at the London Zoo becomes clear when one refers to a quote by Mitchell in 1929: "My rule about no living prey being given except with special and direct authority is faithfully kept, and permission has to be given in only the rarest cases, these generally of very delicate or newborn snakes which are given new-born mice, creatures still blind and entirely unconscious of their surroundings."

[7] Edward Horatio Girling, head keeper of the snake room in 1852 at the London Zoo, may have been the first zoo snakebite victim**.** After consuming alcohol in prodigious quantities in the early morning with fellow workers at the Albert Public House on 29 October, he staggered back to the Zoo and announced that he was inspired to grab an Indian cobra a foot behind its head. It bit him on the nose. Girling was taken to a nearby hospital where current remedies available at the time were tried: artificial respiration and galvanism; he died an hour later. Many respondents to *The Times* newspaper articles suggested liberal quantities of gin and rum for treatment of snakebite but this had already been accomplished in Girling's case. Other recommendations were a bit unnerving: 1) being buried in manure to the neck; 2) application of a white-hot iron or other fiery instrument for at least an hour; 3) solicit a bite from a second snake to neutralize the effects of the first one; and 4) since sleep was always fatal, taking desperate measures to keep the injured party awake. For example, two Indians in the British army had dragged a screaming victim around a verandah for $3^{1}/_{2}$ hrs; death was prevented.

[8] Two of the three most popular exhibits were the aquarium and reptile house at the London Zoo (Balmford 2000).

Artwork and Images Wanted for *HR*

We are always interested in obtaining illustrations of herpetological subjects for publication in *Herpetological Review*. Generally, original drawings should be of a scale that would permit reduction to fit a 90-mm wide column. Original art, or high quality photocopies, should be packaged to ensure safe delivery and sent to the Editor. Alternatively, we would be pleased to receive material in electronic format; consult the Editor for appropriate file formats and sizes.

Also, we are interested in evaluating outstanding color slides or high-resolution digital images of amphibians and reptiles for possible use on future *HR* covers. When reviewing material for submission, photographers should keep in mind the vertical format of our covers. In addition to highlighting outstanding photography, our cover subjects should lend themselves to communication of biologically interesting information through accompanying text. If you would like to have your work considered, please contact the Editor ***prior*** to sending any material. We prefer to review images as JPEG or PDF files before requesting examination of original slides. Postal and e-mail addresses are listed on the inside front cover.

The classification of taxa has always been an area of debate among systematists—empirically, methodologically, and philosophically. Arguably, the single most important change over the past forty years is the widespread recognition that a classification system is only useful when it functions as a storage and retrieval system of phylogenetic information. Although the type of information to be stored has largely been agreed upon (i.e., propinquity of descent and monophyly), debate continues on the method of this system (e.g., PhyloCode: Cantino and de Queiroz 2003; contra Keller et al. 2003; Nixon et al. 2003). Regardless, the role of classification as a subdiscipline of the science of systematics is clear, and it is separate from that of nomenclature, although both are subdisciplines of taxonomy (de Queiroz 2006). Taxonomy is informed by phylogenetics, and this information is used in the naming of biodiversity (nomenclature) and in the organization of the named groups (classification). All systems of classification and nomenclature that are based on evolutionary hypotheses (phylogeny) provide ranks and names for only monophyletic groups. It is from this framework that we address recently proposed changes to the taxonomy of the Colubroidea in North America (NA; Table 1).

One of the largest groups of squamates, the Colubroidea, was recently found to contain a number of families and subfamilies that were determined to be para- or polyphyletic (Kelly et al. 2003; Lawson et al. 2005). The 'traditional' classification, with four families and 15 subfamilies, has remained in this state at least since Dowling and Duellman (1978; although five subfamilies were used as tribes in that work). All of the subfamily names (except Pseudoxyrhophiinae), even those used as tribes in Dowling and Duellman (1978), long predate that publication (Table 2). To rectify this disconnection between phylogeny and taxonomy, establish consistency with phylogenetic hypotheses generated from a large number of morphological and molecular studies (see references in Lawson et al. 2005), and make only modest corrections

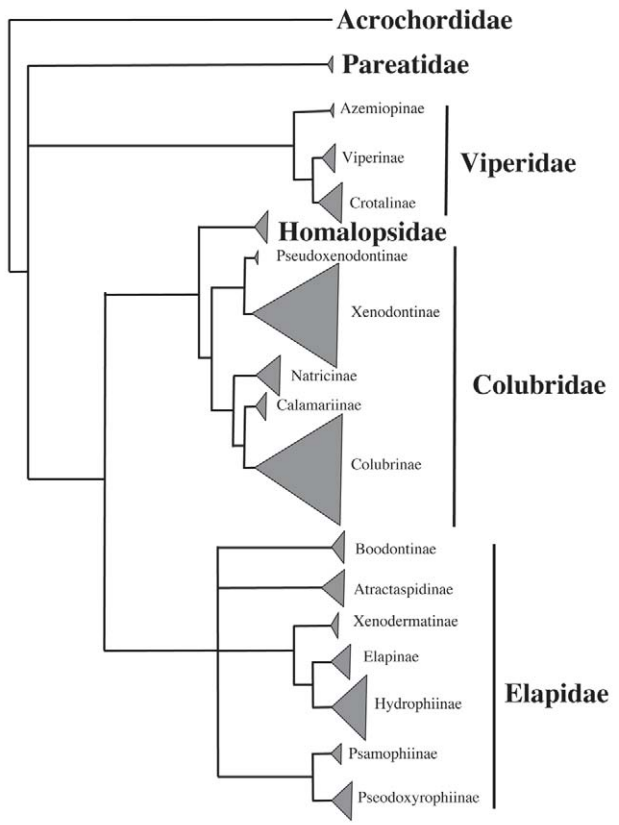

FIG. 1. Phylogenetic relationships of the Colubroidea (including the outgroup Acrochordidae) based on Lawson et al. (2005). The widths of the triangles for families and subfamilies indicate relative numbers of genera.

to the currently used taxonomy, while providing enough information to reflect taxonomic changes, Lawson et al. (2005) proposed a new classification (Table 1; Fig. 1). This classification included the following five families and 15 subfamilies (in parentheses): Colubridae (Calamariinae, Colubrinae, Natricinae, Pseudoxenodontinae, and Xenodontinae), Elapidae (Atractaspidinae, Boodontinae, Elapinae, Hydrophiinae, Psammophiinae, Pseudoxyrophiinae, and Xenodermatinae), Homalopsidae, Pareatidae, and Viperidae (Azemiopinae, Crotalinae, and Viperinae). The only radical change here concerned the inclusion of "nonvenomous" snakes (in the traditional sense) in the Elapidae. However, both venomous subfamilies of the former Elapidae, Elapinae and Hydrophiinae, were retained. This taxonomic decision was based on strong evidence and an application of the oldest family name, Elapidae, to the most recent common ancestor of the node including all aforementioned taxa (Fig. 1).

Collins (2006) suggested that placing the NA colubroid snake genera into the seven basic Linnean categories (Kingdom, Phylum, Class, Order, Family, Genus, and Species) would be more useful because the "layperson" would have difficulty memorizing one extra category, the subfamily. Aside from an unqualified assessment concerning the intelligence of the public on taxonomic matters, the system unilaterally proposed by Collins (2006) destabilizes colubroid classification to an extent possibly worse than the para- or polyphyletic classification in existence prior to Lawson et al. (2005). Here we address several major concerns that the proposal of Collins (2006) would have on colubroid classification. We also present a classification of the NA colubroid snakes that reflects Lawson et al. (2005), which provides the maximum phylogenetic information in this nomenclatural system (Table 1). Finally, we discuss three main areas where the classification of Collins (2006) is detrimental to information storage, communication, and phylogenetic representation.

THE LOSS OF PHYLOGENETIC INFORMATION

By eliminating subfamily from the classification hierarchy, Collins (2006) has effectively reduced the phylogenetic information inherent in the taxonomy proposed by Lawson et al. (2005). The arrangement of the NA Colubroidea in Collins (2006) simply elevates seven subfamilies to familial level while discarding interfamilial relationship. Retaining these as subfamilies nested within families, as suggested by Lawson et al. (2005), reveals information concerning relationships among these subfamilies (Table 1; Fig. 1). For example, it is not clear in Collins (2006) that the Elapidae and Hydrophiidae share a more recent common ancestor with each other than any of the other NA families of the Colubroidea (i.e., Colubridae, Natricidae, etc.).

In classification B of Collins (2006), he misrepresents Lawson et al. (2005) by suggesting this system contains less taxonomic information than his preferred system (classification A; Table 1) because it only reveals three taxonomic groupings for the Colubroidea of NA: Colubridae, Elapidae, and Viperidae. If he were to use the classification system in Table 5 of Lawson et al. (2005) for NA snakes, then it should have been clear that various monophyletic groups within NA are represented by subfamilies nested within families. This not only yields more taxonomic information than Collins (2006), but is more consistent with the historical use of these names and modern phylogenetic hypotheses.

The claim that Collins (2006) represents a standard classification because it refers only to the seven primary Linnaean groupings is also misleading. For example, Collins (2006) only includes two of the Linnaean ranks (family and genus)—a practice that is not commonplace in herpetology. In fact, the oldest use of subfamilies for the Colubroidea dates back to 1768 (Viperinae; Laurenti) and the majority of the others date to the 1800s (Table 2). All the names applied in Lawson et al. (2005) were used in Dowling and Duellman (1978) and are still used by two of the standard college texts on Herpetology (Pough et al. 2004; Zug et al. 2001).

DISRUPTION OF INTERNATIONAL SCIENTIFIC COMMUNICATION

The primary goal of the Linnaean hierarchy is to facilitate accurate scientific communication among researchers living throughout the world and speaking different languages. Elevating the subfamily names for colubroid snakes only occurring north of the Mexican border ignores the higher-level taxonomy of snakes occurring outside of the U.S. and Canada. It does not facilitate scientific communication between researchers speaking different languages when the same taxa found in two different countries are represented by two different classification systems. For instance, 92% of the snake genera in the U.S. and Canada are also found in Mexico (Conant and Collins 1991; Stebbins 2003), but the pro-

TABLE 2. Earliest usage of colubroid subfamily and tribe names adopted by Lawson et al. (2005).

Taxon Name	Author(s)	Dowling & Duellman (1978)
Atractaspidinae	Guenther (1858)	Subfamily
Azemiopinae	Liem et al. (1971)	Subfamily
Boodontinae	Cope (1893)	Tribe
Calamariinae	Bonaparte (1838)	Tribe
Colubrinae	Oppel (1811)	Subfamily
Crotalinae	Oppel (1811)	Subfamily
Elapinae	Boie (1827)	Subfamily
Homalopsinae	Jan (1863)	Tribe
Hydrophiinae	Boie (1827)	Subfamily
Natricinae	Bonaparte (1838)	Subfamily
Pareatinae	Romer (1956)	Tribe
Psammophiinae	Bonaparte (1845)	Tribe
Pseudoxenodontinae	McDowell (1987)	Not used
Pseudoxyrhophiinae	Dowling (1978)	Tribe
Xenodermatinae	Smith (1939)	Tribe
Xenodontinae	Bonaparte (1845)	Subfamily
Viperinae	Laurenti (1768)	Subfamily

posal of Collins (2006) only grants the same hierarchical classification for species in the two countries north of Mexico. Moreover, this taxonomic change does not consider how to place the nearly 90% of other snake genera not found within the U.S. and Canada. For instance, the family Colubridae of Lawson et al. (2005) contains 244 genera in five subfamilies and occurs on all continents except Antarctica. In comparison, the family Colubridae of Collins (2006) addresses only 25 genera, no subfamilies, and only applies to the U.S. and Canada. It is not a grand revelation to understand that species distributions do not coincide with political boundaries. Likewise, classification systems should not be bounded by political borders.

Phylogenetic Inaccuracies

In two cases, the elevation of subfamily to family by Collins (2006) requires a taxonomic decision not in keeping with the phylogenetic hypothesis presented by Lawson et al (2005). The Xenodontinae have typically been divided into two groups: the Xenodontinae representing South American genera and the Dipsadinae representing Central American genera (Cadle 1984; 1985; Crother 1999). For the nine genera of NA xenodontines, Zaher (1999) tentatively placed *Farancia* and *Heterodon* in the Xenodontinae and the remaining genera in the Dipsadinae. Lawson et al. (2005) found a sister relationship between *Farancia* (Xenodontinae) and *Carphophis* (Dipsadinae), which suggests that either the taxonomic contents of the subfamilies are incorrect, or that these groups are artificial. Lawson et al. (2005) contended that their sampling was not adequate to address this issue, so they placed both the Xenodontinae and Dipsadinae under the heading of Xenodontinae in their taxonomic list in Table 5. This classification placed all of the monophyletic Xenodontinae and Dipsadinae under one subfamily, but still made note of the traditional groupings of Xenodontinae and Dipsadinae of Zaher (1999). Collins (2006), without conducting any original phylogenetic research or reanalysis of available data, indicated that the uncertainty in the classification of the Xenodontinae had been solved when he placed *Farancia* and *Heterodon* in the family Xenodontidae and the other NA xenodontines in Dipsadidae. To aid with the description of this putatively paraphyletic classification, he also invented new common names for these subfamilies that do not accurately define either group: slender rear-fanged snakes (Dipsadidae) and robust rear-fanged snakes (Xenodontidae). Again, this classification does not reflect the phylogeny presented in Lawson et al. (2005), creates two paraphyletic groups, and should not be supported.

The ecology of many Neotropical snakes, especially Brazilian species, is poorly known (Cadle and Greene 1993; Vitt 1996). Moreover, published studies are often based on examination of preserved specimens (Marques 1996) and therefore deal mainly with diet and reproduction of particular species (e.g., Bizerra et al. 2005), whereas activity patterns, habitat use and thermal ecology are infrequently reported (e.g., Oliveira and Martins 2001).

The Brazilian Pantanal is a low-lying floodplain covering an area of some 140,000 km^2, consisting of a mosaic of lakes, permanent swamps and seasonally inundated grassy fields with elevated patches bearing forest or cerrado vegetation (Ratter et al. 1988). The Pantanal is located in the Western region of Brazil and eastern Bolivia and is characterized by mean annual temperature of 25°C, and annual precipitation of 1100–1200 mm (Brasil 1997). The Pantanal has low species richness relative to the Cerrado and Amazon, but has some locally abundant snake species, thus facilitating studies of snake ecology (Strüssmann and Sazima 1993).

In spite of being one of the most abundant species in the Pantanal, little is known about the biology of the cat-eyed snake *Leptodeira annulata* in Brazil (Brasil 1997). Moreover, available data on *L. annulata* are largely from the Amazon (Vitt 1996) and Chaco (Lavilla and Scrocchi 1996) biomes. Here we present data on the activity, thermal ecology and habitat use of *Leptodeira annulata* in the Nhecolândia region, Pantanal, collected over five months.

Materials and Methods

Study Site.—The study was conducted from February–May and July 2005 in the vicinity of human habitation at the Nhumirim Ranch (18°98'814"S; 56°61'900"W), Corumbá municipality, Mato Grosso do Sul state, western Brazil. The region has an elevation of around 100 m and consists of a mosaic of lakes, grassland, savanna ("cerrado" vegetation) and semideciduous forest (Ratter et al. 1988).

One-hour searches were conducted on seven days each month, between 1800 h and 2400 h, with two observers searching for snakes in all accessible microhabitats. Each observed snake was considered an activity record; thus, each individual could have been observed more than once during the study. However, no snake was counted more than one time in a day.

We marked all trees (N = 32) at the 4 ha study site and recorded tree height (m) and diameter at breast height (mm). For each snake observed we recorded the microhabitat (tree, ground, building). When possible we caught the snake by hand and took the body, substrate, and air temperature with a cloacal thermometer (Miller and Weber Inc.). We considered snakes as active if they were moving or otherwise observed outside of tree holes.

In the laboratory, we measured snout–vent length (SVL) to the nearest cm using a measuring tape, tail length (TL) and head length (HL) to the nearest mm with a digital caliper (Mitutoyo Corp.), and mass to the nearest g using a Pesola scale. The snakes were sexed by probing. We then marked the individuals with ventral scale clips and released them at the site of capture.

To evaluate sexual size dimorphism we used analysis of covariance (ANCOVA) on tail length, head length, head width, and body mass with SVL as covariate and sex as a factor. Differences in SVL between sexes were tested by *t*-test. We also performed a Pearson's correlation between body vs. air and substrate temperature.

Results

We marked 19 (10F: 9M) *Leptodeira annulata*. Female SVL (481.60 ± 54.41 mm) was not significantly different from male SVL (528.44 ± 99 mm; t = 1.277, P = 0.218). Females also had significantly wider heads and were heavier than males (ANCOVA F = 7.097, P = 0.017, r^2 = 0.358; F = 12.434, P = 0.003, r^2 = 0.470; Table 1).

Observed activity of *L. annulata* (N = 81) occurred mainly between 1830 h and 2330 h, with a peak from 1930 h to 2230 h (Fig. 1). Around 1830 h snakes were observed emerging from tree holes. We found snakes in Acuri palms (*Attalea phalerata*) most often

TABLE 1. Summary of statistics on sexual size dimorphism of *Leptodeira annulata* in the Pantanal, Brazil. Test statistics for head length (HL), head width (HW), tail length (TL) and body mass (MASS) are from ANCOVAs adjusting for SVL, and thus refer to intersexual differences in size.

	Males (N = 9)	Females (N = 10)	Statistical Results
SVL	528.44 ± 99.00	481.60 ± 54.41	t = 1.277, df = 1, P = 0.218
HL	14.12 ± 1.27	14.64 ± 1.69	F = 4.434, P = 0.054
HW	10.15 ± 1.77	11.15 ± 1.93	F = 7.097, P = 0.017
TL	140.11 ± 17.14	139.20 ± 18.56	F = 0.869, P = 0.365
MASS	29.91 ± 7.13	33.70 ± 8.11	F = 12.434, P = 0.003

(63%), followed by fig trees (*Ficus calyptroceras*; 23%) and an unidentified tree species of Leguminosae (6%; Fig. 2). Only 3% of detections were of snakes on the ground. Trees where snakes were located averaged 0.80 ± 0.83 m diameter and snake height on the tree averaged 1.65 ± 0.65 m.

Body temperature averaged 26.8 ± 2.9°C (range 22.5–31.4°C, N = 20 including one recapture) and was positively correlated with substrate (r = 0.92, P < 0.001) and air temperature (r = 0.88, P < 0.001). There was no difference in body temperature between sexes (t = 0.46, P = 0.81).

DISCUSSION

Although we conducted our investigation in close proximity to human habitations, we did observe several *L. annulata* in more pristine environments, indicating that this species occurs in a variety of habitats.

The observed activity of *L. annulata*, a primarily anuran-eating snake (Lavilla and Scrocchi 1986) seems to coincide with amphibian activity, as suggested by Vitt (1996). At our study sites, we observed *Scinax acuminatus* and *Scinax nasicus* during observations, including in the same tree with *L. annulata*. The activity of these amphibians is, in general, restricted to 4–6 h after dark (Cardoso and Martins 1987), which may explain the reduced activity of *L. annulata* after 2230 h. Our sampling efforts however ceased at 2400 h so we cannot say anything about snake activity after midnight.

Although snakes may regulate their body temperature both behaviorally and physiologically (Peterson et al. 1993), the thermal environment (e.g., air and substrate temperature) can influence activity patterns, even in tropical nocturnal snakes (Shine and Madsen 1996). Thus, the observed low snake activity in late evening could conceivably be due to the drop in ambient temperature (Shine and Madsen 1996), rather than due to reduced prey availability as discussed above.

In the Pantanal, *L. annulata* largely used arboreal habitats, in contrast to previous findings (Vitt 1996; Martins and Oliveira 1998). It is notable that the Pantanal has more open habitats (even in forests) than the Amazon, but even so, fewer snakes were found on the ground in the Pantanal. Habitat openness or vegetation cover may affect vulnerability of reptiles to visual predators (Stuart-Fox and Ord 2004). Thus, predation pressure may cause greater use of vegetation and reduced use of open habitats (Watts 1991). Alternatively, taxonomic differences may account for the observed differences, since Vitt (1996) studied the biology of *L. a. annulata*, while we studied the subspecies *L. a. pulchriceps.* It is also possible that our detection probability for terrestrial snakes was lower than for arboreal snakes.

The use of Acuri palms by *L. annulata* may be due to either the ready availability of crevices and holes in the trunk (provided also by *F. calyptroceras* in the study area) or the abundance of this tree, which represents 44% of individual trees on the study site. In pristine areas of the Pantanal at Nhumirim Ranch, Acuri palms are the most common tree species in forests (Ratter et al. 1988).

Due to the short duration of our study, further work is needed to understand seasonal variation in body temperatures, activity and habitat use. The Pantanal has a highly seasonal climate with rainfall restricted to November–March and a flood season from April-August (Junk and Cunha 2005) and these cycles may affect snake biology.

Although apparently abundant, *Leptodeira annulata* is vulnerable to reductions in population size, due to indiscriminate killing of individuals. During our study, two individuals were known to have been killed by local inhabitants. Humans may have a natural

fear of snakes (Greene 1997) and this species in particular is often confused with a venomous snake (the pitviper *Bothrops mattogrossensis*; Lavilla and Sccrochi 1986; pers. obs). Educational programs, especially for children, are necessary in the region to prevent indiscriminate killing of snakes.

Acknowledgments.—We thank Björn Lardner and one anonymous reviewer for comments on a previous version of this manuscript. We are grateful to Christine Strüssmann and Vanda L. Ferreira for making this work possible. We also thank Tami Mott for suggestions and corrections on the English version of this manuscript.

While examining more than 400 skulls of thamnophiine snakes currently assigned to the genera *Nerodia* and *Thamnophis*, we encountered a bone in the snout region of most of the specimens of the Brown Watersnake, *Nerodia taxispilota*, that was not present in any other species we examined—nor are we aware of a comparable osseous element being described in any other snake species. Here we describe and illustrate this neomorph and speculate about its possible function.

The neomorph, which we propose to call the **postnasal strut,** is present in ten of the 16 skulls (62.5%) of *Nerodia taxispilota* we examined (LSUMZ 10569, 16849, 20555, 21062, 24363, 28213–214, 34183, 43155, 43455). The skulls range in length from 22.5–33.1 mm, and represent both sexes (5 females, 4 males, 1 undetermined). Six specimens are from Florida, two from North Carolina, and two from undetermined localities. The six skulls that lack the postnasal strut (LSUMZ 12876, 16851, 16935, 39194, 43159, 43454) range in length from 19.3–35.5 mm, and also represent both sexes (4 females, 2 males). Four are from Florida, two from North Carolina.

The following description is based on the skull of LSUMZ 34183, a large (1029 mm snout–vent length, 33.1 mm skull length) female from Lake Newnan, Alachua Co., Florida. The faintly grooved dorsal surface of the narrow postnasal strut lies essentially in the same horizontal plane as the dorsal laminae of the nasal bones and the dorsal surface of the frontals, hence the strut is readily apparent when the dorsal aspect of the snout region is viewed (Fig. 1, upper). The strut is relatively long, its dorsal surface being nearly 70% as long as the dorsal laminae of the nasals (nearly 60% in LSUMZ 20555; 29.5 mm skull length). The anterodorsal tip of the strut is inserted between the posteromedial ends of the nasals. The posterodorsal tip of the strut is inserted between the anteromedial ends of the frontals, which are deflected laterally to accommodate it, but they are not deflected in snakes lacking the strut (Fig. 1, lower).

In order to better determine the relationship of the strut to the bones around it, we soaked the skull in water for several hours to loosen the dried soft tissue that remained after the initial cleaning by dermestid beetles. Further cleaning was then accomplished by hand-picking tissue with a small needle-nosed forceps. Finally, the entire nasal component was removed when it was discovered

that this could be accomplished without damaging or altering the position of the strut, which apparently has only loose connections to the nasal and septomaxillary bones.

The postnasal strut was thus revealed to be shaped somewhat like an I-beam in cross-section, with the dorsal "crosspiece" being narrower than the ventral one (which expands toward its posterior articulation; Fig. 2). Anteriorly, where the dorsal "crosspiece" extends forward between the posterior ends of the nasal laminae, the ventral "crosspiece" appears to rest on the posterior processes of the septomaxillae—which themselves articulate with the articular facets on the anterior frontals to form the nasofrontal joint.

Posteriorly, the dorsal "crosspiece" sits between the anteromedial ends of the frontals, which it appears to contact only by way of connective tissue (Fig. 1, upper). The ventral "crosspiece," on the other hand, appears to form a three-way articulation with the dorsal tip of the parasphenoid process of the sphenoid medially, and with the descending anteromedial laminae of the frontals laterally. Although the postnasal strut is immobile when the skull is dry, when moistened it is capable of a limited amount of dorsoventral flexure against the fulcrum provided by the dorsal tip of the parasphenoid process.

Discussion.—The presence or absence of the postnasal strut in *Nerodia taxispilota* clearly does not reflect sex, size, or geography, so the genetic potential for its development appears to exist throughout the genome. Failure to find any trace of the strut in 55 skulls of *N. rhombifer*, the sister taxon of *N. taxispilota*—or in any of the smaller series of other *Nerodia* species available to us—strongly suggests that the presence of the strut in *N. taxispilota* is an autapomorphic feature of the species.

In the absence of studies of its functional morphology, we can

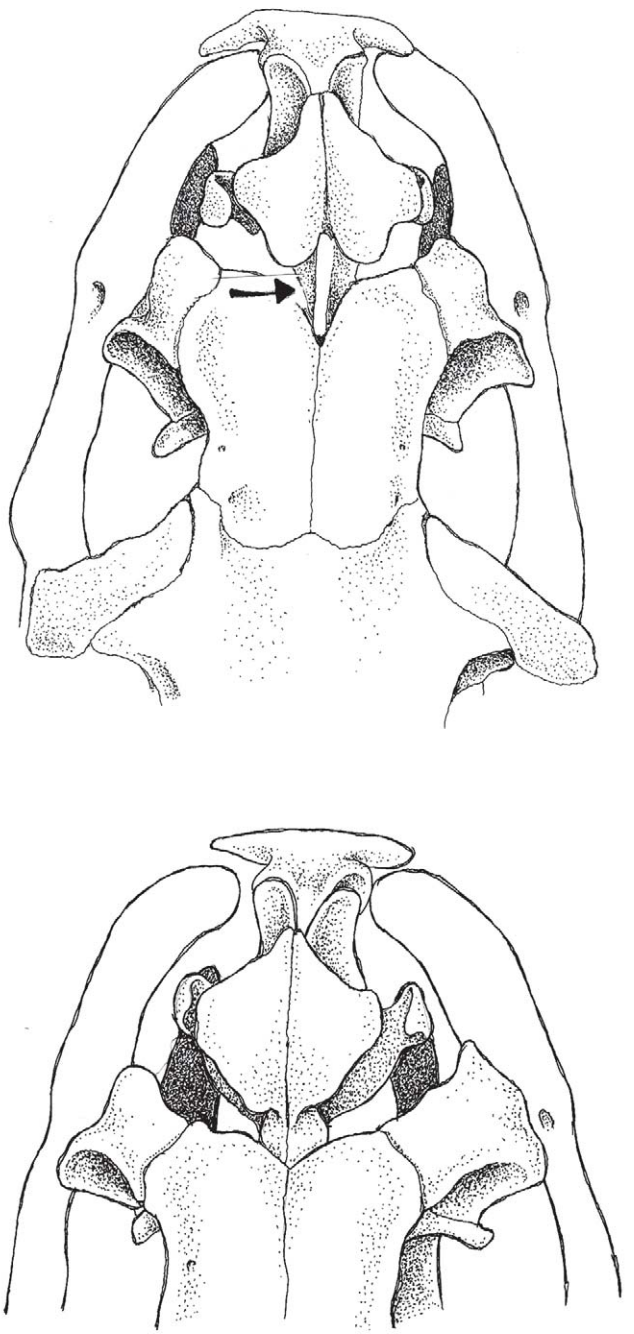

FIG. 1. Dorsal views of skulls in *Nerodia taxispilota* with (upper, LSUMZ 20555), and without (lower, LSUMZ 16851), the postnasal strut (arrow).

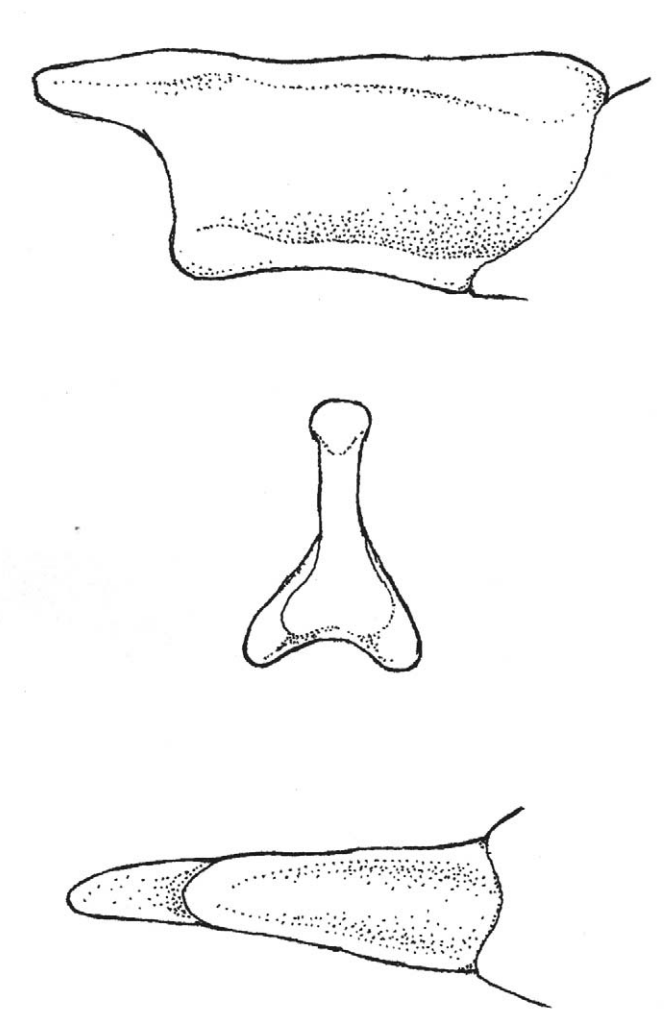

FIG. 2. Lateral, frontal, and ventral views of the postnasal strut in *N. taxispilota* (LSUMZ 34183).

only speculate about the role of the postnasal strut. The most obvious possibility is that by bracing against the frontals posteriorly, the strut serves to limit the dorsal flexion of the nasal component at the prokinetic nasofrontal joint during prey manipulation (Albright and Nelson 1959). Whether or not the strut could also restrict axial rotation at that point is less clear, but it remains a possibility (Cundall and Shardo 1995).

Assuming there is some adaptive advantage to limiting dorsal flexion of the snout in *Nerodia taxispilota*, what might it be? The Brown Watersnake is a catfish specialist (Gibbons and Dorcas 2004) that, in the course of ingesting its prey, must overcome the obstacles posed by the catfish's erected-and-set pectoral and dorsal spines. Richmond (1944) gave a detailed description of how this was accomplished by one large individual he observed closely. When the snake's jaws reached the base of the spines, they slid up them for a short distance, then the snake paused and maintained pressure on them until the struggling fish relaxed the spines. This permitted the snake to close its jaws down on the spines and prevent them from being re-erected.

We suggest that a more rigid snout would more effectively maintain pressure on the catfish spines than could a more flexible snout. Perhaps in the postnasal strut we may be seeing a novel morphological adaptation that is in a stage of evolution where it has become widespread but not yet fixed. Yet, the strut's absence in *Nerodia rhombifer*, equally a catfish specialist (Gibbons and Dorcas 2004), is puzzling. Clearly, a sophisticated study of the strut's function in living *N. taxispilota* will be required to test our speculations.

Acknowledgments.—We wish to thank C. Austin (Museum of Natural Sciences, Louisiana State University) for granting permission to partially disarticulate the skulls of two specimens on loan to us. We are also indebted to D. Cundall (Lehigh University) for reading a draft of this manuscript and offering constructive criticism.

Courtship Behavior of Two Treefrog Species, *Aplastodiscus arildae* and *A. leucopygius* (Anura: Hylidae), from the Atlantic Rainforest, Southeastern Brazil

JULIANA ZINA*
and
CÉLIO F. B. HADDAD
Departamento de Zoologia, Instituto de Biociências
Universidade Estadual Paulista, Caixa Postal 199
13506-970 Rio Claro, São Paulo, Brazil

**Corresponding author; e-mail: juzina@rc.unesp.br*

Complex courtship behaviors in anurans have been described mostly in dendrobatids (e.g., Juncá 1998; Limerick 1980; Roithmair 1992; Wells 1977). Nevertheless, recent studies on reproductive behavior of hylids revealed complex courtship behaviors, mostly in the genus *Aplastodiscus* (e.g., *A. leucopygius*: Haddad and Sawaya 2000; *A. perviridis*: Haddad et al. 2005; *A. eugenioi*: Hartmann et al. 2004). The courtship of these hylids involves mutual tactile stimuli and egg deposition in a subterranean nest previously constructed by the male, who guides the female to the nest.

Visual communication plays an important role in courtship contexts of diurnal frog species (e.g., Haddad and Giaretta 1999; Pombal et al. 1994). Recently, visual signaling has been considered an important type of communication also for nocturnal frogs where this communication seems to be more common than previously thought (Hartmann et al. 2005). Giasson and Haddad (2006), Hartmann et al. (2004), and Heying (2001) described visual signaling during the courtship of *Hypsiboas albomarginatus*, *Aplastodiscus eugenioi*, and *Mantella laevigata* respectively, providing evidence that the courtship behavior of nocturnal frogs is more complex than previously known and visual signals are employed by nocturnal species of frog of different genera or families.

Aplastodiscus arildae belongs to the *Aplastodiscus albofrenatus* species group and *A. leucopygius* to the *A. albosignatus* species group (Faivovich et al. 2005), both restricted to the Brazilian Atlantic rain forest. Information on the courtship behavior of the *A. leucopygius* is available in Haddad and Sawaya (2000). These authors described the courtship as a complex behavioral sequence that involved mutual tactile stimuli and egg deposition in a subterranean nest previously constructed by the male, who guided the female to the nest (reproductive mode 5 according to Haddad and Prado 2005). There is no documentation of the courtship behavior of *A. arildae* since this species occurs at low population densities (Zina and Haddad 2007) making the probability of observation very low. The aims of our study were to describe the courtship behavior of *A. arildae* and compare it with the courtship behavior of *A. leucopygius*. In addition, we provide new information on the visual communication in the courtship behavior of *A. leucopygius*.

Methods.—Our study was conducted in the Serra do Japi (23°14'S, 46°56'W, 1030 m elev.), Municipality of Jundiaí, State of São Paulo, southeastern Brazil, between March 2004 and Janu-

ary 2006. Field observations began after sunset and finished when reproductive activity ended each night. During this period we monitored all the calling males of both species in the studied sites (stream, lake, and swamp). The period of observations had a mean duration of 06 h 47 min ± 2 h 25 min (N = 21; range = 2–9 h) per night. Focal animal observations were used to record behavior (Lehner 1996). We followed the nomenclature proposed by Wells (1977) to classify the different types of calls (advertisement and courtship calls) emitted by both species, according to the social context. To observe courtship behavior, we used headlights with weak batteries to reduce disturbance to the frogs.

Results.—We observed 20 courtship sequences of *Aplastodiscus leucopygius* and only one of *A. arildae*. The courtship behavior of *A. arildae* consisted of a complex sequence of tactile stimuli. The pair behaved as follows (Fig. 1): A—the male was calling parallel to the ground on a leaf 1.5 m above the ground; B—the female jumped onto a leaf next to where the male was calling, and when the male noticed the presence of the female, he stopped emitting the advertisement call; C—the female touched the male's snout with her hand; D—the female repeatedly tapped the male with her snout; E—the female touched the male's snout with her hand; F—the male moved himself slightly and started to move one foot up and down repeatedly, beating it against the leaf; G—the male moved again and positioned himself face to face with the female; H—the female moved one foot up and down repeatedly, beating it against the leaf; I—the male repeated this behavior; J—the female positioned her head above the male's head; L—the male moved slightly preparing himself to get down from the leaf were the couple stayed for two hours; M—the male started a descending journey from his perch, emitting courtship calls; N—the male stopped emitting courtship calls and the female followed the male, touching him with her hand; O—after three hours from the beginning of courtship, the pair reached the ground, and the female continued to follow the male, touching his dorsum with her hand. This courtship occurred during a rainy night over more than nine hours. The pair separated after a branch fell down next to them.

We observed 10 complete courtship sequences (prior to the female approaching the male) of *A. leucopygius*, which had a mean duration of 4 h 30 min ±1 h 20 min (N = 10; range = 2–7 h). These started with the female approaching the male, and ended with the entrance of the pair into the subterranean nest. Another 10 sequences were observed from the moment when the females were already close to the males. During the observation of the journey of the couples to the subterranean nest we observed two behaviors that were not reported by Haddad and Sawaya (2000): 1) both females (N = 5) and males (N = 8) of *A. leucopygius* passed their hands over their eyes and/or blinked when facing each other; and 2) during this interaction, we also observed males performing toe trembling (N = 6). After the oviposition occurred, males abandoned the subterranean nests and females did the same soon after the males. The time that a pair spent in the subterranean nest until the exit of the male averaged 4 h ± 1 h (N = 15; range = 3–5 h). Males of *A. leucopygius* (N = 14) returned to their calling sites three days or more after having been observed in courtship.

Fifteen of 20 courtship sequences observed for *A. leucopygius* ended in oviposition. In three courtship sequences observed during nights of intense rain in December 2004, females came out of the subterranean nest soon after they had entered, and oviposition did not occur. Nests on those occasions were almost entirely full of water. In January 2005, we observed three courtship sequences; two of them were interrupted when the pairs were inside the subterranean nest, due to the incidental interference of the observer trying to visualize the oviposition behavior inside the subterranean nests. In these two situations, we observed the males at the entrance of the nest, while the females were inside with their snouts smeared with mud.

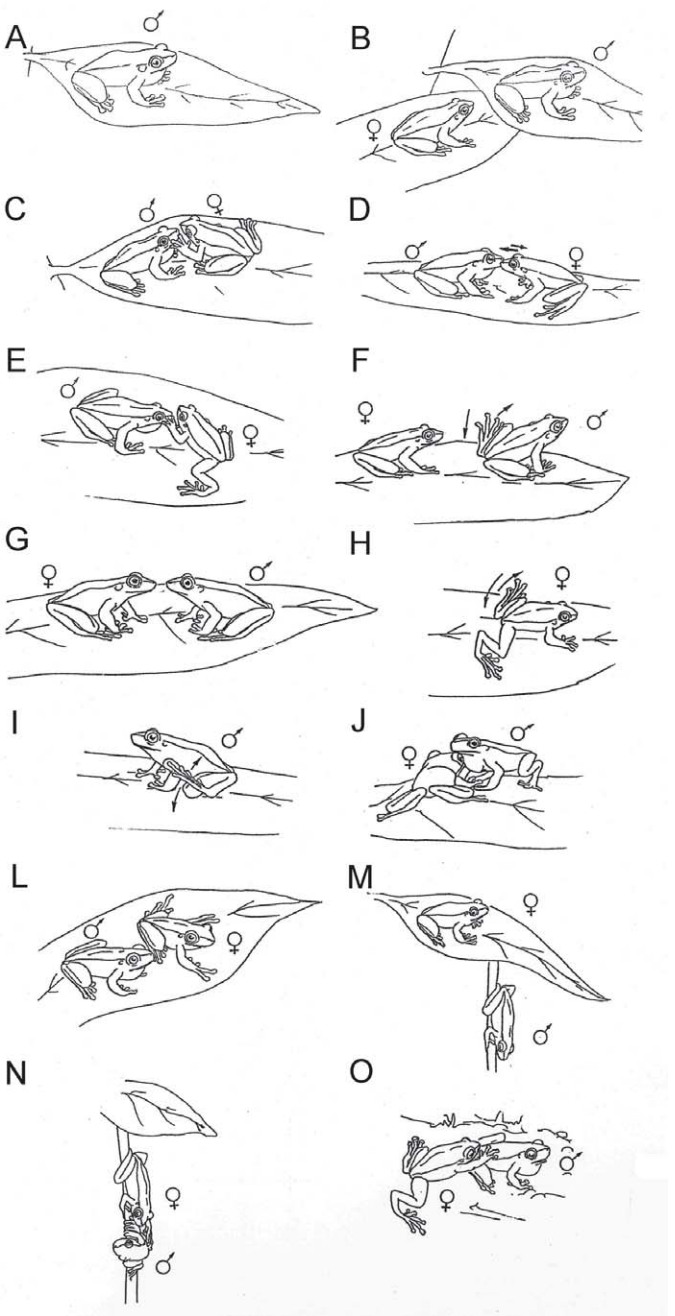

Fig. 1. Behavioral sequence of the courtship behavior of *Aplastodiscus arildae* from the Serra do Japi, Municipality of Jundiaí, São Paulo, Brazil. Letters A– O refer to the behavioral sequence (see text).

On two occasions, an individual of *Hypsiboas bischoffi* (Hylidae) jumped close to the leaf where a male of *A. leucopygius* was emitting advertisement calls. In both occurrences the males of *A. leucopygius* started to emit courtship calls.

TABLE 1. Courtship behaviors (X) observed for different species of *Aplastodiscus*.

Species	Visual signaling				Tactile signaling			Reference
	Toe or fingers trembling	Limbs/foot moved up and down	Eye blinked	Female raised herself on all four limbs	Passed the leg or foot across own body	Female positioned the head above male's head	Male and/or female touched each other with snout or hand	
A. arildae	—	X	—	—	—	X	X	Present study
A. eugenioi	X	X	—	—	X	X	X	Hartmann et al. 2004
A. leucopygius	X	—	X	—	—	X	X	Haddad & Sawaya 2000; Present study
A. perviridis	—	—	—	X	—	—	X	Haddad et al. 2004

Discussion.—Tactile stimuli between male and female and the behavior of guiding the female to the oviposition site are typical of anuran species in which males construct nests before the arrival of females (e.g., *A. perviridis*: Haddad et al. 2005; *Hylodes asper*: Haddad and Giaretta 1999; *A. leucopygius*: Haddad and Sawaya 2000; *A. eugenioi*: Hartmann et al. 2004; *Leptodactylus fuscus*: Martins 1988).

Our observations of the courtship behaviors of *Aplastodiscus leucopygius* were similar to those described by Haddad and Sawaya (2000); however, we registered two more behaviors that were not observed by those authors. Until now, specialized courtship behaviors similar to that observed for *A. leucopygius* and *A. arildae* were described only for *A. perviridis* (Haddad et al. 2005) and *A. eugenioi* (Hartmann et al. 2004). According to Hartmann et al. (2004), *A. eugenioi* produced visual signals during courtship, which are considered an unusual communication mode for nocturnal anurans. Contrasting colors and postural displays in anurans may be related to conspecific visual communication (e.g., Wells 1980a, b). During the courtship of *A. leucopygius* we observed that males and females blinked at each other and/or passed their green hands over their red eyes, a behavior that may involve visual communication. A similar behavior was performed by *Brachycephalus ephippium* (Anura, Brachycephalidae), where the males passed their yellow hands over their black eyes during agonistic interactions (see Pombal Jr. et al. 1994). This behavior, as well as the visual behaviors of *A. leucopygius*, may produce a color contrast for the receiver. According to Pombal et al. (1994), this visual behavior in *B. ephippium* may be derived from a cleaning behavior observed for this species. Descriptions of visual signals are uncommon in frogs and are predicted to be predominantly employed by diurnal species at sites with an unobstructed view (Endler 1992). Leg shaking is involved in visual communication (see Hödl and Amézquita 2001). It was observed during the courtship of *A. eugenioi* (Hartmann et al. 2004) and during aggressive interactions between males of *Aplastodiscus perviridis* (Toledo et al. 2007). In our study, we observed foot shaking behavior in *A. arildae* during the courtship sequence. While this is a visual signal as described by Hödl and Amézquita (2001), we cannot discard the possibility of seismic communication, in which the female or male perceive the presence of other individuals by the propagation of low frequency signals in the substrate or vegetation.

Although visual communication may appear to be less effective than acoustic communication for nocturnal species of frogs, as a consequence of light limitations, the combination of these two communication types might be very important for females to localize the males during the courtship behavior. This may be especially important for species of *Aplastodiscus* because males move constantly from one place to another on their way to the subterranean nest. Acoustic communication is mainly used in long-distance communication (Rand 1985). Visual signaling might be very efficient for short-distance communication in nocturnal frogs (e.g., distance between male and female during the courtship) and might be involved with the coordination of female and male during the journey to the subterranean nest. We did not observe the end of the courtship behavior in *A. arildae*. Because the courtship behavior observed for *A. arildae* is similar to that performed by the other species of this genus (*A. perviridis*: Haddad et al. 2005; *A. leucopygius*: Haddad and Sawaya 2000; *A. eugenoi*: Hartmann et al. 2004) we presume that it ends in a subterranean nest where oviposition occurs. The similarities of the courtship of *A. leucopygius* and *A. arildae* with the other species of the genus (Table 1) support this behavior as being synapomorphic at the genetic level. The perception of an individual by its movements on the vegetation was observed for *A. leucopygius* male, which started to emit courtship calls as soon as another conspecific or heterspecific individual jumped next to them. However, experiments using appropriate equipment to measure seismic signals are necessary to confirm if this additional communication mode is used by this species. In summary, for *A. leucopygius* and *A. arildae* we observed at least three types of male-female communication during courtship behavior (acoustic, visual, and tactile).

During intense rainy nights in December 2004, the courtship sequences of *A. leucopygius* did not end in oviposition. Nests, in these occasions, were almost entirely filled with water. Lack of oviposition following courtship suggests that the females inspect the nests and may reject males if the nests are not adequate. Another fact which suggests that the nests are inspected by females was their snouts smeared with mud, observed when they were already inside the nests. This behavior was not known for the species and could mean that females may not only inspect the nest,

but also modify it before oviposition, a behavior previously observed in other species that construct mud nests such as *Hypsiboas faber* (Martins and Haddad 1988).

The American Crocodile (*Crocodylus acutus*) is one of two native species of crocodilians found in southern Florida, USA. It occurs primarily in estuarine environments in extreme southern mainland Florida and northern Florida Keys (Kushlan and Mazzotti 1989; Mazzotti 1999). In Florida, habitat loss due to development along coastal areas of Palm Beach, Broward, Miami-Dade, and Monroe counties has been the primary factor endangering the American crocodile. This loss of habitat principally affected nesting range of crocodiles, restricting nesting to a small area of northeastern Florida Bay and northern Key Largo by the early 1970s (Kushlan and Mazzotti 1989; Ogden 1978). At this time most remaining crocodiles (about 75% of known nests) were in Florida Bay in Everglades National Park (ENP) or on North Key Largo (25% of known nests), with few sightings (no nests) in Southwest

Florida. The American Crocodile was declared endangered in 1975 by the U.S. Fish and Wildlife Service (Federal Register 40:44149).

In 1978 a third nesting area was discovered at the Florida Power and Light Company, Turkey Point Power Plant site (TP) (Mazzotti 1983). During the 1980s monitoring programs were established for all three nesting locations. These monitoring programs focused on nesting, growth, and survival of crocodiles and led to the discovery of an additional nesting area in the Cape Sable/Flamingo area of ENP. The outlook for crocodiles in Florida is more optimistic today, and currently the Florida population of *C. acutus* is under review for reclassification from endangered to threatened by the U.S. Fish and Wildlife Service (Federal Register 70:15052–15062). In addition to endangered species recovery, the federal government, in partnership with state, local, and tribal governments, has initiated the South Florida Ecosystem Restoration Initiative (SFERI). This is an unprecedented effort to restore and manage ecosystems of southern Florida that have been degraded by human activities. Alternatives for improving water delivery into South Florida estuaries may change salinities, water levels, and availability and suitability of nesting habitat in receiving bodies of water. Continued monitoring will be essential to ensure survival of this endangered species within its changing environment.

Surveys for nesting of *C. acutus* have been conducted in ENP since 1970 (Ogden 1978). Mazzotti (1989, 1999) summarized factors affecting nesting success from 1970 to 1995. The purpose of this paper is to review nesting of *C. acutus* in Everglades National Park to 2004.

Methods.—This study was conducted at the southern tip of mainland Florida from US Highway 1 to and including Cape Sable, ENP (Mazzotti 1999). The mainland has very low relief with many creeks, ponds, small bays, and a few man-made canals and ditches draining into Florida Bay (Mazzotti 1983, 1999). Marl banks that line creeks, canals, and sand beaches on mainland and island shorelines are important as nesting sites for crocodiles (Mazzotti 1999). Vegetation in the study area is primarily mangrove swamp (Olmstead et al. 1981). Higher ground supports tropical hardwoods and buttonwood (*Conocarpus erectus*) (Olmstead et al. 1981). The presence of plants intolerant of flooding is a good indicator of potential nesting habitat for crocodiles (Mazzotti 1989).

Since 1978 consistent survey methods have been used under supervision of one investigator (FJM) to collect the data analyzed here. Crocodile nesting effort (number of nests with eggs) and success (number of nests that produce at least one hatchling) were determined by searching known and potential nesting habitat in ENP. Searches were conducted by skiff, foot, and canoe during April and May for nesting effort and July and August for nesting success. Evidence of nesting activity included tail drags, digging, or scraping. Shells of hatched eggs or hatchlings were considered evidence of successful nests. When nests were located, vegetation, habitat (creek, island, shoreline, or man-made), substrate, distance from shore, nest dimensions, and salinity of adjacent water were recorded. Successful nests produced at least one hatchling. The number of failed eggs and causes of egg failure were noted when evident. Nests that failed to hatch were located by excavating areas of nesting activity at least 30 days after the last known nest hatched for that year.

Trends in numbers of nests in northeastern Florida Bay (1978–2004) and Cape Sable/Flamingo (1986–2004) nesting areas were analyzed using log linear regression models. Trends in numbers of nests in different habitats (island, creek, shoreline, artificial) also were analyzed using log linear regression models. We compared proportion of nests lost to depredation and embryonic mortality during 1985 to 1995 to the proportion of nests lost to those factors during 1997 to 2004 using a Fischer's Exact Right-Sided test. The proportion of nests lost to depredation and embryonic mortality in natural versus artificial surfaces was analyzed using a

Results.—The number of crocodile nests observed in ENP increased from 16 in 1997 to 55 in 2004 (Fig. 1). With the exception of a single nest on Shark Point near the mouth of Shark River, the footprint of crocodile nesting remained the same as that reported by Mazzotti (1999). Nesting increased in the historical core area of northeastern Florida Bay at an annual rate of 2.5% from 1978 to 2004 ($P = 0.0006$, $R^2 = 0.4219$). However, most of the increase in crocodile nesting occurred in the relatively new Cape Sable/Flamingo nesting area, where nests increased from 2 in 1986 to a high of 35 nests in 2004, an annual rate of 14.1% ($P = 0.0003$, $R^2 = 0.5648$). Prior to 1995, 90% of crocodile nests (N = 328) were located in northeastern Florida Bay. Since 1997, 45% of crocodile nests (N = 222) were located in the Cape Sable/Flamingo nesting area (Table 1).

The number of crocodiles nesting in different habitats has also changed (Table 1). The number of creek nests decreased at an annual rate of -4.3% ($P < .0003$, $R^2 = 0.4585$), whereas the numbers of nests on man-made substrates increased at an annual rate of 10.5% ($P = 0.0008$, $R^2 = 0.4956$) (Table 1). All nests on artificial substrates were in the Cape Sable/Flamingo area. Most (70 of 94) nests on artificial substrates were on canal banks. Other artificial nest sites included spoil piles (4), parking lots (9), roadside (10), or canal plugs (1). The number of nests on mainland and island shorelines increased at annual rates of 5.7% ($P < 0.0001$, $R^2 = 0.7026$) and 4.3% ($P = 0.0036$, $R^2 = 0.3250$), respectively, between 1978 and 2004.

Overall nesting success has remained high in ENP (Table 2). The proportion of nests lost to depredation increased slightly and the proportion of nests lost to embryonic mortality decreased slightly in the period 1997–2004 as compared to 1985–1995 (Right-sided Fisher Exact Test, $P = 0.0556$ for depredation and $P = 0.0313$ for embryonic mortality). Depredated nests were distributed randomly between artificial and natural substrates (Pearson Chi-square Test, $P = 0.3546$, N = 456), as was embryonic mortality (Pearson Chi-square Test, $P = 0.8153$, N = 449).

Discussion.—The number of nests of the American Crocodile in ENP has increased fivefold from 1978 to 2004 and more than doubled since 1997 (Fig. 1). Although a slight increase has occurred in the core nesting area of northeastern Florida Bay, most of this increase can be attributed to the new Cape Sable/Flamingo nesting area of ENP. Most of those nests were on artificial substrates (Table 1). Hence, in ENP as elsewhere in Florida, most of the increase in crocodile nests was on man-made substrates in areas where crocodiles did not nest historically.

Nesting occurred within a few years of creation of peat canal banks created at TP and the Crocodile Lake National Wildlife Refuge (CLNWR; Mazzotti 1983; Ogden 1978). In ENP, crocodiles nested on a canal plug within hours of construction completion (Mazzotti 1999). However, most of the increase in nesting in the Cape Sable/Flamingo area was on canal banks that were created more than 40 years ago (Beard 1938; Lodge 1994). Mazzotti et al. (2007) hypothesized that plugging canals in the Cape Sable/Flamingo area in the 1980s and 1990s to reduce saltwater intrusion and retain fresh water provided more suitable habitat for nesting for the few crocodiles present in the area and for growth and survival of hatchling crocodiles. The rapid increase in numbers of crocodiles nesting in the Cape Sable/Flamingo area since 2000

TABLE 2. Patterns of nesting success and failure of American Crocodiles observed in Everglades National Park between 1970 and 2004. Successful nests are those that produced at least one hatchling. Data from Ogden (1978), Mazzotti (1989, 1999), and present study.

*most embryonic mortality is caused by flooding and desiccation (Mazzotti 1989, 1999)

may be the result of offspring of the original nesting crocodiles entering the breeding population.

The decrease in creek nests coincides with sea level rise (Mazzotti et al. 2007; Simmons and Ogden 1998). Not only did crocodiles formerly nest more frequently along creek banks, but some of the creek banks were farmed in the early 1900s (Moore 1953a). That suggests that water salinity and water levels were lower than at present. Current estimates of sea level rise suggest that water levels around Florida Bay have been rising at a rate of 38 cm/100 yr since 1932 (Wanless et al. 1994). Canal banks are at higher relative elevations than creek banks, are less susceptible to flooding, and may possibly provide additional nesting habitat as sea level continues to rise.

Although the number of island nests has increased, crocodiles have not returned to nest on many of the islands where they were known to nest in the 1950s (Moore 1953b; Ogden 1978). Instead, crocodiles are now nesting on islands close to the mainland in northeastern Florida Bay. We hypothesize that the overall increase in nests on islands and on the mainland shoreline is related to an increase in relative density of crocodiles in the area. Nesting islands in the southern portion of northeastern Florida Bay were probably used by crocodiles from Key Largo and were abandoned when crocodile habitat on Key Largo was developed (Ogden 1978). Islands in central Florida Bay, like islands in northern Florida Bay, are in an area where we suspect relative density of crocodiles has increased (Mazzotti 1999). Yet, there has not been a corresponding increase in nesting on those islands. One possible explanation is that nesting surveys have shown that elevated nesting beaches are no longer present on any of the islands in central Florida Bay mentioned by Moore (1953b). The cause of the loss of nesting beaches on those islands is unknown but could be the result of storm erosion (Mazzotti 1989), sea level rise, or both.

Nesting success of the American Crocodile in Everglades National Park compares favorably to nesting success of American Crocodiles elsewhere (Arteaga and Gomez 2000; Schubert 2002; Thorbjarnarson 1989) and other species of crocodilians (Allsteadt 1994; Hall and Johnson 1987; Metzen 1978; Webb et al. 1983). In Florida, nesting success in ENP is intermediate between that found at the TP nesting area (highest) and at CLNWR (lowest; Mazzotti et al. 2007). In ENP, nest failure is the result of embryonic mortality caused by flooding or desiccation, and depredation by raccoons (Mazzotti 1989, 1999). For example, nesting in ENP is timed to avoid the wettest and driest times of the year, and embryonic mortality is limited to years with extreme rainfall events (Mazzotti 1999). Sand nests were more susceptible to desiccation and creek nests were most susceptible to flooding. With fewer creek nests embryonic mortality has been reduced (Mazzotti 1999).

Depredation of crocodile nests by raccoons in Florida has only occurred in ENP, despite the presence of raccoons at both of the other nesting areas (TP and CLNWR) (Mazzotti et al. 2007; Moler 1992). One difference among the nesting areas is that, until recently, all nesting at TP and CLNWR was on man-made substrates whereas most nesting in ENP was on natural substrates. However, when nesting on man-made substrates began in ENP, it appeared as if those nests were particularly vulnerable to depredation (Mazzotti 1999). That trend has not continued (this study).

If the pattern of increasing numbers of nests and good nest success continues, the data would support reclassification of the American Crocodile from endangered to threatened. This underscores the importance of long-term monitoring programs for endangered species recovery. The response of nesting crocodiles to the plugging of canals to restore more natural salinity patterns in interior wetlands confirms the value of crocodiles as indicators of ecosystem response to restoration projects. Also, this highlights the value that relatively simple projects can have for endangered species recovery and ecosystem restoration.

Acknowledgments.—We thank the many field biologists who worked with us over the years, often under harsh field conditions, to collect these data. We thank the U. S. National Park Service and the U. S. Army Corps of Engineers for their support for this project. We are especially grateful to Sonny Bass, Jon Moulding, and Skip Snow from those agencies for their commitment to research and monitoring of crocodiles in Everglades National Park. Kirsten Hines and Joy Vinci helped with preparation of this manuscript. All permits and approval for use of an endangered species were obtained from the appropriate authority and are available for inspection upon request to the senior author.

aaron.fenner@flinders.edu.au

Anurans living in arid and semi arid environments have to overcome high temperatures and a seasonal lack of water (Bentley 1966). Many arid zone frogs avoid desiccation from high temperatures and water loss by burrowing (Bentley 1966; Main et al. 1959). Some species also form a cocoon for further protection from desiccation and water loss until the next heavy rains that may be three or more months away (Lee and Mercer 1967). Anurans living in arid environments must adapt their breeding strategies to take advantage of water when it is available. Consequently, desert species may not breed for several years (Bragg 1967; Main et al. 1959; Morton et al. 1993). Many species living in arid areas will breed whenever water becomes available regardless of the time of year, usually following heavy rain (Bragg 1967). Hence, they may have non-seasonal but extremely restricted breeding periods usually only lasting two or three days (Bragg 1967; Main et al. 1959). As water is only available for a limited amount of time, metamorphosis is often accelerated, ensuring offspring have enough time to complete development before the water source has dried up (Bragg 1967; Main et al. 1959; Read 1999).

The reproductive biology of some Australian myobatrachid frogs, including those in the genus *Neobatrachus*, is poorly understood. This is especially true when compared to the well-studied North American pelobatids, including *Spea* and *Scaphiopus*, that appear similar in their basic biology and ecology to Australia's myobatrachids, particularly those in the genus *Neobatrachus* (Read 1999). Opportunistic breeding occurs in pelobatids, usually following rain (Bragg 1967; Woodward 1982). Fast development from egg to metamorph (e.g., from 7 to 40 days) occurs in most *Spea* and *Scaphiopus* species (Bragg 1967; King 1960; Voss 1961). The speed of development has been shown to be affected by water levels, water temperature, food availability, and competition and cannibalism from conspecifics (Bragg 1967; Morey and Reznick 2000; Pfennig 1990; Semlitsch and Caldwell 1982). Skeletochronology studies suggest that these frogs are relatively long lived (> 13 years) and may take two or more years to reach maturity (Tinsley and Tocque 1995; Woodward 1982). However, comparable data are lacking for many of the species in the genus *Neobatrachus*.

Herein, I provide some new data on the general reproductive biology, occurrence of summer breeding and accelerated larval development in *N. pictus*. I also highlight similarities between the Australian *Neobatrachus* and the North American pelobatids.

Neobatrachus pictus is a locally common burrowing frog found in southern South Australia and in western Victoria (Cogger 2000). It occurs in a wide range of habitats from open grasslands and mallee woodlands, and in farmed and cleared land (Barker et al.

1995; Robinson 1995), usually near dams, claypans or ditches where water pools after rain (Robinson 1995). Currently, *N. pictus* is thought to breed at any time of the year, usually following heavy rain (> 25 mm) (Roberts 1978). Breeding and calling have been observed in the late austral summer and early autumn (February and March) as well as throughout winter and into the early spring (Roberts 1978). Males call from the water while floating (Roberts 1978). Larval life has been reported to be 4–9 months (Anstis 2002; Barker and Grigg 1977).

Methods and Results.—Frogs were observed at two study sites near Burra (33°42'S, 138°56'E), in the mid-north of South Australia. Site 1, Rosalea, is located approximately 10 km S of Burra and is surrounded by ploughed fields. Site 2 is located on the outskirts of Burra in natural grassland that is grazed by sheep. After a prolonged dry period (< 100 mm in previous 6 months), heavy rain fell consistently between the 18 and 21 January 2007. Total rainfall over the four days was 82 mm at Site 1 and 88 mm at Site 2. One dam was monitored at Site 1 (Dam 1, length × width = 38.8 m × 27.2 m) and two dams located approximately 1 km apart at Site 2, one small (Dam 2, 15.7 × 14.9 m) and the other large (Dam 3, 108 × 33.5 m). All three dams are man made and dug out of clay, and all were dry and empty prior to the rain event. On 23 January the water levels within the dams were measured and depths recorded were 1.7 m, 1.6 m, and > 2 m for Dams 1, 2, and 3 respectively. When possible, all three dams were inspected daily from the onset of rain to monitor larval development.

Breeding observations.—On 21 January *Neobatrachus pictus* called at all 3 dams from ~ 2100 h to at least 0100 h; there were no calls heard prior to 21 January. Ten captured specimens were confirmed to be *N. pictus*, based on their size, call and lack of skin connection from the knee to the side of the body that distinguishes them from other *Neobatrachus* spp. in the region (Roberts 1978), and were released back to their capture locations.

The choruses lasted 5 days, to 25 January, with no frogs heard or observed on or after 26 January. Male *N. pictus* called from the water and the water's edge and their numbers and location within the dam across the 5 nights at Site 1 were visually estimated (Table 1). From 22 to 24 January, egg masses were seen at night but were not visible the following mornings at ~ 0900 h. Amplexus, however, was not observed at any of the dams. Adult *N. pictus* were found over 300 m away from the dam at Site 1. A second frog species, *Limnodynastes tasmaniensis*, was present at Dam 1 from 23 to 25 January in much lower numbers (visual estimate: 15 animals per night). Ambient temperatures were recorded between the 21 to 25 January 2007 using a data logger located at Site 1. Temperatures ranged from 11.3–24.1°C between 2130 h and 0430 h, during the five days of the chorus.

Tadpoles.—Tadpoles were first observed in all three dams on 2 February 2007. Tadpoles aggregated in large groups, 50–100 individuals, in the shallow water and many appeared to come to the water's surface frequently to gulp air. The water at Site 2 was very clear and more than 1000 tadpoles could be seen at each of the dams. However, at Site 1 it was difficult to estimate tadpole numbers due to the muddy water.

Tadpoles were first observed with hind legs on 14 February. Front legs were observed in some individuals on 20 February. Tadpoles with no legs were present until 26 March 2007 at all three dams. However, by 6 April 2007, water levels were very low (< 30 cm) at Dam 1 (Site 1) and Dam 2 (Site 2) and all remaining tadpoles had died, with many seen dead in the shallows and on the banks of the dams.

TABLE 1. Estimated numbers of *Neobatrachus pictus* and their locations around the dam during five breeding nights at Rosalea, Site 1, in South Australia.

Date	No.	Location
21 Jan 2007	60+	Highly visible near waters edge
22 Jan 2007	60+	Highly visible near waters edge
23 Jan 2007	40+	Edge and in middle of dam
24 Jan 2007	20+	Few near edge most in water
25 Jan 2007	20+	Few near edge most in water

Metamorphs.—Metamorphs were first observed at all dams on 26 February 2007, and then were observed nightly until the 5 April 2007. There were no observable differences in metamorphosis rates between the frogs in ploughed land or natural grassland, or between large or small dams. This suggests that *N. pictus* can develop from egg to metamorph in ~ 37 days. On 27 February 2007, 16 metamorphs were collected from Site 1 between 2030 h and 2120 h, from up to 10 m away from the water's edge. The captured metamorphs were measured for snout–vent length, head length (snout tip to posterior tip of jaw articulation), head width (behind eyes and between the tips of the jaw), tibia length (leg flexed), remaining tail (vent to tip of tail) and weight (to the nearest gram) (Table 2). The metamorphs were then returned to their place of capture. Metamorphs were observed over 200 m from the nearest dam. Three specimens were collected and deposited into the South Australian Museum (SAM) (SAM reference numbers: R62503-5).

Discussion.—My study is the first to document summer breeding and accelerated development of *N. pictus* in the semi-arid landscape of South Australia. It is also the first reported case of *N. pictus* breeding in January, and confirms the temporal flexibility in breeding time in this species (Roberts 1978). This observation also highlights the similarities between the *Neobatrachus* of Australia and the North American pelobatids.

Neobatrachus pictus from near Burra, South Australia, had an accelerated rate of metamorphosis compared to other published accounts (Anstis 2002; Barker et al. 1995), reaching froglet stage after only a few weeks (37 days), rather than 4–9 months, if conditions are suitable (Anstis 2002; Barker et al. 1995). Fast meta-

TABLE 2. Metamorph *Neobatrachus pictus* body measurements (N = 16) of specimens collected from Rosalea, Site 1, South Australia.

Body Measurement	Range	Mean (SD)
SVL (mm)	21–27	23.5 (1.46)
Head length (mm)	8–10	8.75 (0.68)
Head width (mm)	8–10	8.75 (0.68)
Tibia (mm)	7–9	8.19 (0.75)
Tail remaining (mm)	3–21	7.56 (4.21)
Weight (grams)	2–3	2.19 (0.40)

morphosis has been recorded for *N. centralis* with metamorphosis taking as little as 17–40 days (Read 1999). This rapid development is comparable with the North American pelobatids living in similar environments (Bragg 1967). The benefits of fast metamorphosis include maximizing recruitment (Newman 1989; Wilbur 1987), and enhanced survival when early developers can attain larger sizes and mature earlier than slow developers (Berven 1990; Smith 1987). It is also an advantage to species living in environments with unpredictable rainfall and areas where water is only available for short periods of time (Bentley 1966). Many species of *Neobatrachus*, including *N. pictus*, may overwinter as tadpoles and develop in the spring (Anstis 2002). However, flexibility in the breeding strategy, as shown by *N. pictus*, may also be present in congeners, possibly allowing breeding or larval development to take place at any time of year if conditions are suitable. Further studies would need to be conducted to fully understand the factors that trigger the accelerated larval development in *N. pictus*.

In my study, there was no apparent difference in the rate of larval development in the dams in natural grasslands and ploughed fields, or between large and small dams. However, I only measured dam depth and size. Other studies have found differences between development rates due to water levels, water temperature, food availability and competition (Bragg 1967; Morey and Reznick 2000; Pfennig 1990; Semlitsch and Caldwell 1982). These factors should be considered in future studies.

Acknowledgments.—I thank C. M. Bull and M. N. Hutchinson for reading and commenting on the early version of this manuscript. I also thank the reviewers M. Tyler, J. D. Roberts, and D. H. Olson for their valuable comments for the revised manuscript. I would also like to thank the land holders R. Sawers and G. & R. Strachn for access to their properties. A museum incidental collection permit (M253661) was issued by the South Australian Department for Environment and Heritage, to M. N. Hutchinson (South Australian Museum), with A. Fenner as an affiliate.

Some Forgotten Descriptions of *Nasikabatrachus* (Anura: Sooglossidae)

INDRANEIL DAS
Institute of Biodiversity and Environmental Conservation
Universiti Malaysia Sarawak, 94300, Kota Samarahan, Sarawak, Malaysia
e-mail: idas@ibec.unimas.my

Much excitement was justifiably generated in the recent past in association with the description of a purported new family of amphibians (the Nasikabatrachidae) by Biju and Bossuyt (2003). Dubbed 'the coelacanth of frogs' (Hedges 2003), its sole described member, *Nasikabatrachus sahyadrensis*, is restricted to the Western Ghats complex of Southwestern India, a known biological diversity hotspot (see also Aggarwal 2004; Gadagkar 2004). Another research group described its tadpole and added details of adult morphology and confirmed a relationship with the African Heleophrynidae and the Seychellian Sooglossidae (Dutta et al. 2004). Most recently, Frost et al. (2006) synonymized Nasikabatrachidae under Sooglossidae. Two recent papers have discussed the distribution of this enigmatic frog (Andrews et al. 2005; Das 2006).

These recent papers, however, make no mention of several early papers that described in detail (for the first time), the tadpoles and post-larval stages of *Nasikabatrachus*, including osteological details of adults, and inference to an African relationship.

The first report of tadpoles that are clearly *Nasikabatrachus* is in Annandale and Rao ("1916" 1917), who provided a brief de-

scription, based on specimens from Kerala State, Southwestern India. In another paper, Annandale (1918) provided an extended description and measurements, and presented illustrations of the body and mouthparts, tentatively assigning the species to the family Cystignathidae (at present synonymous with Leptodactylidae). Subsequently, Annandale and Hora (1922) remarked on the similarities between their unidentified tadpole, which they considered closely related to *Heleophryne*, and wrote: "No frog of the family Cystignathidae is known from the Oriental Region, but the Batrachia of the hills of the Malabar Zone are still imperfectly studied and the adult of this tadpole is a burrowing form and, therefore, liable to escape notice. The Ethiopian affinities of the fauna of the Malabar Zone are well recognized by Zoogeographers." The larva was also discussed in a paper on convergent evolution of torrent fish and tadpoles by Annandale and Hora (1922). Later, Rao (1938) reexamined some of the early specimens, as well as a metamorph, and inferred a relationship of the Indian frog with the African Heleophrynidae (using *Heleophryne natalensis* as a representative) and Hemisotidae (comparisons made with *Hemisus*), rather than to any Asian taxa, but clearly diagnosed the Indian taxon as different, writing of the justification of "creation of a new genus or even a sub-family for their reception." The Sooglossidae, to which family *Nasikabatrachus* was allocated by Frost et al. (2006) was described by Noble only in 1931. Two other papers which describe the cranial osteology of *Nasikabatrachus* (tentatively allocated to the family Cystignathidae) include Ramaswami (1943) and Ramaswami (1944), while noting its non-confamilial status.

The description (p. 22) and images (Pl. I; figs. 6, 6a) of the tadpoles provided in Annandale (1918) of a species *incertae sedis* match the description of *Nasikabatrachus* provided by Dutta et al. (2004), including: 1) dorsoventrally flat; 2) reduced tail fin; 3) beak with keratinized labial teeth rows; 4) sinistral spiracle; 5) cloacal tube with flap-like extensions ventral to tail fin; 6) ventrally-located suctorial mouth; 7) head large; and 8) the dorsal orientation of the eyes and nostrils. Dutta et al. (2004) mentioned an additional character that is at variance with the description in Annandale (1918)—a white head. Specimens reported in that paper were examined several years after preservation, which might explain the discoloration of head and body, described as "dark grey with small black spots." A uniquely derived character of the Nasikabatrachidae—funnel-shaped cloacal tube—is not mentioned in the early description, perhaps because of the technical limitations of the optics of the time. Both Annandale (1918) and Dutta et al. (2004) describe the tadpoles as being torrenticole in habits. Adult and metamorph descriptions in Annandale (1918) and Rao (1938) match *Nasikabatrachus* in the following: 1) inner metatarsal tubercle spade-like; 2) sternum absent; 3) firmisternal pectoral girdle; 4) lateral end of coracoid wider than median; and 4) hind limbs dark with a white inner metatarsal tubercle.

Aggarwal (2004) pointed out that *Nasikabatrachus* was familiar to the local people, revealing once again the failure of science to pay enough attention to local knowledge. In this short communication, I show that early workers in India, in a series of forgotten papers published nearly a century ago, have remarkably predated the discovery of a new species and genus of an ancient group of frogs. They also arrived at a conclusion on relationships rather similar to that confirmed using contemporary knowledge on morphology and molecular techniques.

Acknowledgments.—I thank A. M. Bauer, G. V. A. Gee, D. J. Gower, A. Haas, V. Wallach, and an anonymous reviewer for literature and comments.

The New World coralsnakes are currently allocated to three genera: *Micruroides*, *Micrurus*, and *Leptomicrurus* (Campbell and Lamar 2004). The monotypic Sonoran coralsnake (*Micruroides euryxanthus*) is likely the sister taxon to all other New World coralsnakes, and is morphologically distinguished from the other genera by having a single pair of gular shields and by the presence of solid maxillary teeth situated posterior to the fangs. Zweifel and Norris (1955) recognized two subspecies of *M. euryxanthus* (*M. e. euryxanthus* and *M. e. australis*), distributed from southern Arizona and New Mexico south through Sonora and western Chihuahua, Mexico. *Micruroides e. australis* has subsequently been collected from extreme northern Sinaloa, Mexico. In 1967, Roze described the taxon *M. euryxanthus neglectus* on the basis of two male specimens collected between 25–32 km north of Mazatlán, in southern Sinaloa. Since its description, no additional specimens of *M. e. neglectus* have been reported. Furthermore, no specimens of *Micruroides* have been collected from the region intervening the type locality of *M. e. neglectus* in the south and extreme northern Sinaloa, a hiatus of over 400 km.

On 17 July 2006, we obtained a specimen of *Micruroides* from near Cosalá, Sinaloa (24.293°N 106.759°W; 289 m elevation) that we identified as *Micruroides e. neglectus* based on color pattern and scalation (Figs. 1A, B). The specimen is notable in that it is the first known female of the taxon to be deposited in a herpetological collection (Museo de Zoología, Facultad de Ciencias [MZFC], Universidad Autónoma de México: MZFC 19683), and is the first specimen reported since the original description. In most aspects of morphology MZFC 19683 is consistent with the description of the holotype provided by Roze (1967): the specimen has 13 black body rings and 2 black tail rings; black body rings 5–7 dorsal scales long; a pale nuchal ring 3.5 scales long not extending onto parietals; pale body rings 1.5–2 scales long; and 13 unmelanized red body rings. There are a total of 112 red scales along the middorsal line of the body (excluding the tail), which is the highest number reported for *Micruroides*. MZFC 19683 has 226 ventrals (males of *M. e. neglectus* have 206–207), and 24 subcaudals (males have 25–26). The specimen has a snout–vent length of 390 mm and a tail length of 28.9 mm.

Although broadly associated with the arid Sonoran Desert region of southern Arizona and northwestern Mexico, the distribution of *M. euryxanthus* is locally restricted to regions that receive

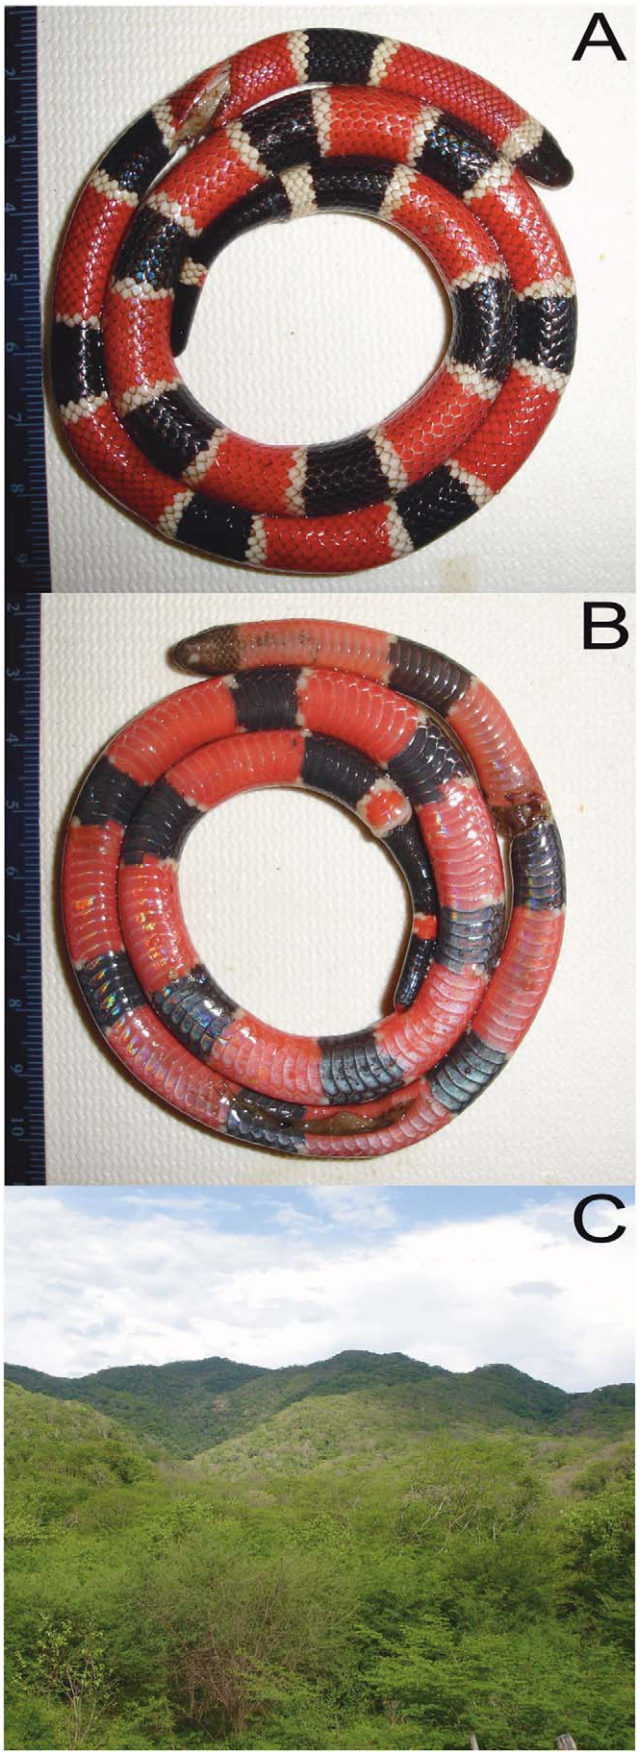

FIG. 1. Dorsal (A) and ventral (B) aspects of *Micruroides euryxanthus neglectus*, adult female (MZFC-19683); (C) tropical deciduous forest near the collecting locality.

relatively high amounts of summer rainfall; thus throughout most of its range its primary habitats are subtropical thornscrub and palo verde cacti desert (*sensu* MacMahon 1985). Over the north to south axis of Sinaloa, the transition from thornscrub to tropical deciduous forest is gradual; the new specimen was obtained from tropical deciduous forest (Fig. 1C), similar to that of the type locality of *M. e. neglectus*. It was found crossing a paved road (Sinaloa Hwy 8) during warm, humid conditions at approximately 2219 h. During the same night, several other snake species were encountered near the collecting locality, including a similarly patterned *Lampropeltis triangulum*.

Most coralsnakes are ophiophagus, consuming primarily small colubrids and typhlopids (Campbell and Lamar 2004). Considerable information exists on the diet of *Micruroides euryxanthus* but not from the extreme southern portion of its distribution. The specimen collected near Cosalá contained the partially digested remains of a small colubrid snake, *Hypsiglena torquata* (MZFC 19684). The snake had been swallowed head-first and only about the posterior third of the body was undigested. As far as we have been able to ascertain, this is the first reported incidence of a non-captive coralsnake consuming *H. torquata* (reviewed in Campbell and Lamar 2004).

The new locality for *M. e. neglectus* is situated approximately 100 km northwest of the type locality in the vast region indicated by Campbell and Lamar (2004) to be of probable, but unknown, occurrence for the species. The new specimen partially fills in this gap in the distribution of *Micruroides*; however, considerable distance still exists between the specimens assigned to *M. e. neglectus* and known *Micruroides* populations to the north. Future collecting efforts will likely substantiate the presence of *Micruroides euryxanthus* throughout Sinaloa. Furthermore, efforts are currently underway to evaluate and revise the taxonomy of all New World coralsnakes, including *Micruroides* (ENS et al., in prep).

Acknowledgments.—We are grateful to J. Campbell for reviewing a draft of this manuscript. Necessary permits were provided by SEMARNAT. We thank O. Flores-Villela for facilitating use of collecting permits. This study was partially funded by a grant from T&E Inc. to JMM. Funding for ENS was provided by the National Science Foundation (grant no. DEB-0416160) and the Instituto Bioclon.

An Anole Lizard Preserved in Colombian Copal

The term 'copal' is generally used for any hard, semi-fossilized resin produced by diverse broadleaf and coniferous trees found in both the Old and New World. In Colombia, large amounts of resin are often seen hanging from the branches of the leguminous tree *Hymenaea courbaril*, commonly known as the *algarrobo*. Through a process of oxidation and polymerization, this resin gradually hardens—particularly after exposure to sunlight (Lagenheim 1995). The result is a highly durable material named after the Aztec *copalli*, meaning 'resin.' Copal is easily mistaken for amber but is softer and, when heated, burns with a smoky flame (Rice 1980). A drop of a suitable non-polar solvent (e.g., acetone) on copal causes it to become sticky, whereas on true amber there is no reaction. It can take upwards of three to four million years for copal to acquire the properties of amber (Poinar 1992).

Large amounts of fossiliferous material from Colombia are readily available on the market as either semi-fossilized copal or fossilized amber, most of it from the Departamentos de Bolívar, Antioquia, Santander, Boyacá, and Tolima (Poinar 1996). Studies of the nuclear magnetic resonance (NMR) spectra of samples from the Departamento de Santander map almost perfectly to those of modern *H. coubaril*, indicating that they are geologically immature and should be classified as copal (Lambert et al. 1995). In addition, copal from Colombia has always contained recent, extant species of insects (DuBois and LaPolla 1999; Rice 1980).

In the late 1990s a polished piece of Colombian copal, 68.9 mm in length with a diameter of 20.6 mm and weighing 16.3 g, was purchased by Michael Oschin of Temecula, California, from a private collector in Florida (Fig. 1). The copal is from the Departamento de Santander, where most of it comes from near the towns of Bucaramanga, Vélez, and Girón (Poinar 1992, 1996). The piece is unusual for its anole lizard inclusion. The anole is approximately 31 mm in snout–vent length and consists primarily of skin fragments from the left side of the head, the left forelimb, the right forefoot, and the lower two thirds of the body; the latter is represented by a shell of skin and includes approximately the first third of the tail. Skeletal elements include the left maxilla, portions of the left forelimb and right forefoot, the pelvis, parts of the hindlimbs, and a number of tail vertebrae.

In a letter appraising the copal, dated November 16, 1999, James C. Wyatt of Garland, Texas, mentions site visits to the "Amazon Jungle, Santandre [sic] Province, Colombia" by "geologist Allen Gratham of Ardmore, Oklahoma." According to Wyatt, Gratham dated the piece from the Miocene series (23.8–5.2 mya) based on stratigraphy. Wyatt also mentions an unnamed "recent researcher, a geophysical chemist," who estimated the age of the copal at "less than two million years." After Wyatt assigned it a commercial retail value of US $25,000, Oschin donated the copal to the Natural

History Museum of Los Angeles County (LACM 153260), where it was included in an exhibit on organisms preserved in amber.

Five resin-preserved anoles have previously been documented (Böehme 1986; de Queiroz et al. 1998; Lazell 1965; Polcyn et al. 2002; Rieppel 1980), although others are known to exist. All five specimens are preserved in amber from the Dominican Republic, two of which were described as new species: *Anolis electrum* Lazell 1965, and *A. dominicanus* Rieppel 1980. The present study is unique in that it examines the first known resin-preserved anole from South America.

Materials and Methods.—The anole inclusion was X-rayed in the Ichthyology Section of the Natural History Museum of Los Angeles County with Faxitron Model 43855C, set at 2.5 mA and 30 kV. Exposure settings were at 60, 120, 180, and 240 sec. The radiograph images were then scanned and enhanced with the Microsoft computer program PhotoDraw. In the Museum's Section of Mineralogy, a 1.0 mm section was sliced from one end of the copal with a Buehler Isomet Precision Saw and sent to Beta Analytic Inc. in Miami, Florida, for radiometric analysis. The rest of the copal was transferred to the Section of Ichthyology for digital photomicrography. Using a Polaroid DMC 1 digital camera in tandem with a dissecting microscope, photographs were taken at 120× magnification of the left loreal region of the head, and at 250× magnification of the left forelimb, left forefoot, and base of the tail. The photographs were later enhanced using PhotoDraw and the following details noted: condition of scales on the anterior portion of the forelimb; condition of middorsal scales at the base of the tail; number of loreal rows under the second canthal; proximity of subocular scale rows relative to supralabials; number of supralabials to below center of eye; and number of subdigital lamellae under fourth toe of left forefoot.

Results.—The X-rays revealed the presence of transverse processes on the autotomic caudal vertebrae (Fig. 2), identifying the specimen as a β-anole (Etheridge 1959). These anoles have been found to be the most derived among the polychrotids (Poe 2004).

The following diagnosis was made from the digital micrographs: scales on anterior portion of forelimb unicarinate (Fig. 3A); middorsal scales at base of tail keeled and slightly enlarged (Fig. 3B); six loreal rows under second canthal, suboculars separated from supralabials by one row of scales, and eight supralabials to below center of eye (Fig. 3C); and 16 subdigital lamellae under fourth toe of left forefoot (Fig. 3D).

The results of the radiocarbon dating were reported in pMC (percent modern carbon) units rather than years BP (before present). With a measured radiocarbon age of 115.4 ± 0.4 pMC, the sample had more ^{14}C in it than the modern reference standard. This excess is attributed to thermonuclear bomb testing during the 1950s (D. Hood, in litt.).

Discussion.—The copal was still respiring carbon post-1950s, implying that the specimen was alive within the last 50 yrs. Of the three possible species of β-anoles currently known from the Departamento de Santander—*A. auratus*, *A. sulcifrons*, and *A. tropidogaster* (Ayala 1986), *A. auratus* was eliminated because of its large, keeled ventrals. *Anolis sulcifrons* was also ruled out because of its smooth supradigital scales (Myers 1971). After comparison with preserved specimens from Colombia, the copal anole agrees most closely with *A. tropidogaster*.

The results of this study emphasize the need for qualified scientists in preventing the misinterpretation of copal specimens. In

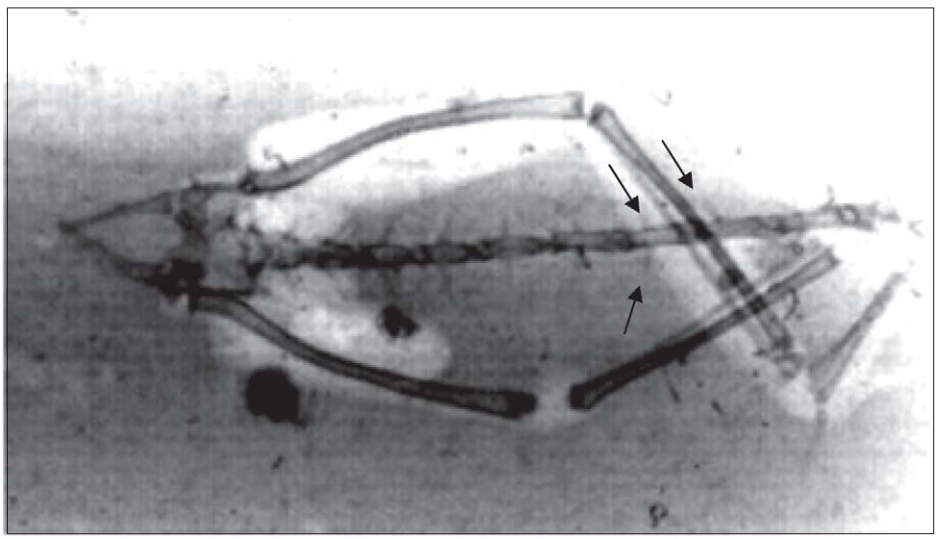

FIG. 2. X-ray radiograph of specimen, showing pelvic region with elements of the hindlimbs and tail. Arrows indicate the presence of transverse processes on the autotomic caudal vertebrae.

this instance, commercial fossil collectors and dealers were initially responsible for the authentication of the copal. The appraisal letter alone contained a number of egregious mistakes. To begin with, the Departamento (not Provincia) de Santander lies within the Valle del Magdalena and is entirely isolated from the Amazonian region by the Cordillera Oriental de Colombia. Second, the name of the geologist from Ardmore, Oklahoma, is Allen Graffham (not Gratham), of Geological Enterprises, Inc. (DuBois and LaPolla 1999). Finally, determining the age of copal based solely on stratigraphy can be highly misleading, as copal is easily re-deposited by water (it floats) or during landslides (DuBois and LaPolla 1999).

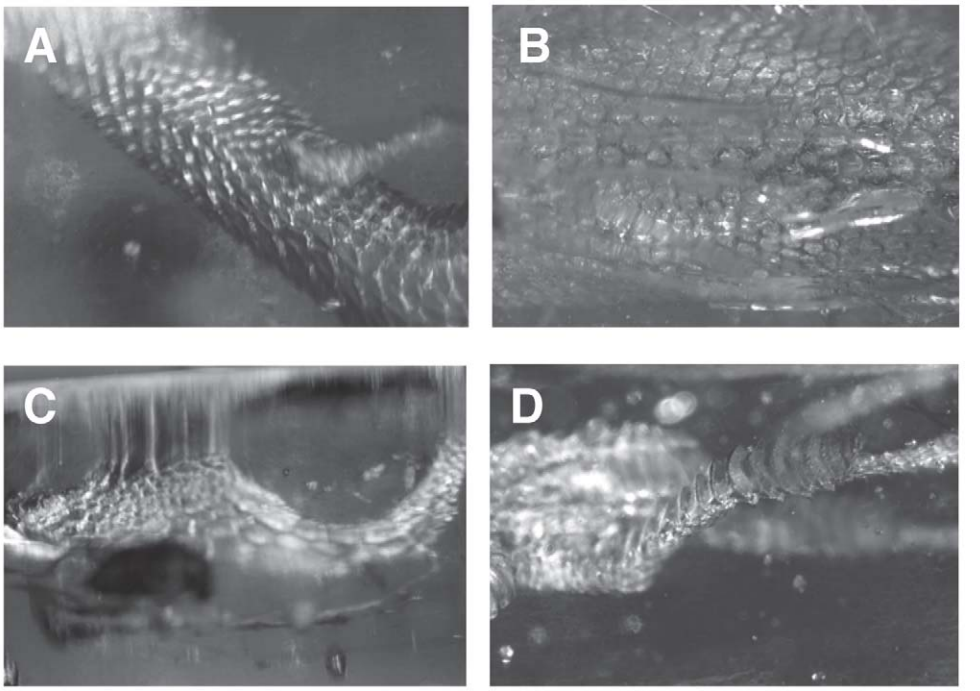

FIG. 3. (A) Scales on left forelimb (250× magnification); (B) dorsal scales at base of tail (250×); (C) scales of loreal region (120×); (D) subdigital lamellae under fourth toe of left forefoot (250×).

Acknowledgments.—This study would not have been possible without the kindness and generosity of M. Oschin. Thanks also to D. Kizirian and the following individuals, who contributed their valuable time and services: J. Seigel, R. Feeney, and D. Ettensohn; K. Oliva; A. Summers and R. Jacinto; D. Hood; and G. Poinar. Inspiration was provided by D. Buth.

Genetic Verification of Possible Gigantism in a Southern Toad, *Bufo terrestris*

D. BRUCE MEANS

1313 Milton Street, Tallahassee, Florida 32303, USA
e-mail: means@bio.fsu.edu

and
STEPHEN C. RICHTER
Department of Biological Sciences
Eastern Kentucky University, Richmond, Kentucky 40475, USA
e-mail: stephen.richter@eku.edu

Ectothermic vertebrates are well known for indeterminate growth, a process by which animals continue to grow throughout life, although the rate of growth slows with age. Maximum size is a morphological characteristic of amphibians and reptiles that is useful in species identification (Conant and Collins 1998), but because of indeterminate growth, older, larger individuals are occasionally found, necessitating periodic revisions of the size information available for species. Examples of true gigantism (abnormally large size) have not been reported in amphibians, probably because it is difficult to know whether an exceptionally large-sized individual represents the far end of the normal size distribution of a species or whether some other phenomenon is operating such as acromegaly, a genetic anomaly that influences the overproduction of growth hormones (Ferone et al. 2004).

The maximum reported size of *Bufo terrestris* is 113 mm SVL (Conant and Collins 1998). On 18 December 2003, Brenda Boland found a large toad (Fig. 1) in her yard near the town of Wacissa, Jefferson Co., Florida (30°21'31"N, 83°59'14"W). The female toad (sex later determined by dissection) measured 150 mm SVL and weighed 193.6 g. This specimen is 33% longer than the previous maximum SVL reported for *B. terrestris* and about 1335% larger by weight than the average Southern Toad (14.5 g) determined by weighing a sample of 10 live adults (8 males, 2 females) from a site (30°21'08"N, 84°18'30"W) 33 km to the west in adjacent Leon County, Florida. The normally pronounced knobs and high cranial crests, diagnostic for *B. terrestris*, were present but extremely exaggerated in this individual; dark, dorsal spots contained one to three warts, themselves larger than normal (Fig. 1). Although the external morphology of the giant toad was consistent with that of *B. terrestris*, we wanted to verify this with genetic data. Therefore, we compared its mtDNA with samples of known *B. terrestris* and previously published sequences of *B. americanus*, *B. fowleri*, and *B. terrestris* by Masta et al. (2002).

Toes were preserved in 95% ethanol from 5 *Bufo terrestris* collected on 4 March 2002 in Leon County, Florida just south of Tallahassee (30°21'08"N, 84°18'30"W). One toe from the large toad was collected on 5 June 2004. All samples were stored in 95% ethanol until DNA was extracted. DNA was extracted from each individual using a Qiagen® DNEasy Tissue Kit. For each individual, DNA was PCR amplified for a mitochondrial genome region that began at the 3' end of 16S gene and spanned $tRNA^{Leu(UUR)}$, ND1 gene, $tRNA^{Ile}$, $tRNA^{Gln}$, $tRNA^{Met}$, and to the 5' end of ND2 gene using primers Bw16S-L and BwND2-H developed by Masta et al. (2002). This region was chosen because primers had been developed and because sequence data were available on GenBank for *B. americanus*, *B. fowleri*, and *B. terrestris*.

PCR products were prepared for sequencing using a Qiagen® QIAquick PCR Purification Kit to remove carried over primers, dNTPs, buffers, enzymes, and non-target DNA. Purified products were then used in sequencing reactions. Sequencing reactions for each primer and individual were performed using ABI Prism® BigDye Terminator Cycle Sequencing Ready Reaction Kit (Applied Biosystems). These products were ethanol precipitated, dried, and resuspended in Template Suppression Reagent (Applied Biosystems) in preparation for loading into an automated DNA sequencer. Nucleotide sequence data were then collected using an ABI Prism® 310 Genetic Analyzer and DNA Sequencing Analysis Software™ Version 3.4.5 (Applied Biosystems). Sequences were aligned and edited using Sequencher™ version 4.1.4 (Gene Codes Corporation).

Two individuals each of the three morphologically similar toad species were haphazardly chosen from Table 1 of Masta et al. (2002) with the following GenBank accession numbers: *B. americanus* (AF462491; AF462500), *B. fowleri* (AF462507; AF462522), and *B. terrestris* (AF462529; AF462530).

A total of 1062 bases were sequenced and aligned for 5 *B.*

FIG. 1. Giant *Bufo terrestris* female with normal-sized adult female on her back.

terrestris and the large toad. Of these, 757 overlapped with sequences from the *Bufo* study of Masta et al. (2002). The sequence data for the 5 *B. terrestris* and gigantic toad had identical nucleotides at all 1062 positions. Based on the alignment of the four toads in this study and six GenBank sequences, six species-specific positions occurred within the 757-base segment of overlap. All identified the four toads in this study as *B. terrestris* (i.e., the nucleotide at each of the six positions were the same as the two *B. terrestris* from GenBank and differed from *B. americanus* and *B. fowleri* from GenBank.

Because this toad is so much larger than one would expect from a normal distribution of *Bufo terrestris* SVLs, we believe it is not simply the largest toad of its kind but represents a case of abnormal growth. Several causes are possible. Interspecific hybridization is unlikely because only *B. quercicus*, a tiny species, is sympatric with *B. terrestris* in the area where our giant toad was found. If our giant toad's father (mtDNA tells us the mother was a *B. terrestris*) was an escaped or naturalized alien species such as *B. marinus*, we should have seen some morphological expression of his genes, but in all external characteristics, the giant toad has only *B. terrestris* morphology. Moreover, the large natural size difference between a female *B. terrestris* and a male *B. marinus* would seem to preclude amplexus in this pair.

Acromegaly results from excessive growth hormone in adults and usually results in an overgrowth of bone and connective tissue that produces coarse facial features, hands, and feet (Van Der Lely et al. 2005). We have found no published studies of acromegaly in cold-blooded vertebrates, so we do not know how acromegaly presents in amphibians except to say that our giant toad does not have any grossly coarse features of the head, hands, and feet. We cannot rule out another possible cause, genome multiplication, because we didn't assay nuclear DNA. The simplest and most likely cause, in our opinion, is gigantism, the result of excessive growth hormone secretion that begins in juvenile humans and other animals (Tortora and Derricksen 2005).

Environmental pollutants such as fertilizers, herbicides, and pesticides have all been shown to influence amphibian growth and development (Boone and Bridges 2003; Halliday 2000; Relyea 2005). We cannot say whether the size of our giant toad is the result of the effects of one or more of these chemical agents, but body deformities, inhibition of larval growth, and survival of populations and species of amphibians are of increasing concerns to herpetologists (Lannoo 2005; Semlitsch 2003).

Abnormal size due to genome multiplication remains to be tested in our giant toad. We have been unable to locate any literature on gigantism or acromegaly in amphibians, so it is important that this example may be the first of its kind to be reported.

We were unsuccessful in getting the toad to breed. She was found dead in her cage on 02 February 2005, preserved in 95% ethanol, and was deposited in the Florida Museum of Natural History (UF 144211) and is available for further study.

Acknowledgments.—Kenneth L. Krysko, Wayne King, Kevin Enge, Paul Moler, and Max Nickerson of the Florida Museum of Natural History verified the size and identity of the giant toad. Michael P. Krick of Pet Paradise, Tallahassee, Florida, kindly loaned us the specimen for study.

A Simplified and Inexpensive Method for Extraction and Quantification of Tetrodotoxin from Tissue Samples

ELIZABETH M. LEHMAN
Department of Biology, Indiana University
1001 East Third Street, Bloomington, Indiana 47405, USA
e-mail: lehmanem@gmail.com

Tetrodotoxin (TTX) is a potent neurotoxin that blocks sodium channels, preventing the propagation of action potentials, causing paralysis and eventually death (Miyazawa and Noguchi 2001). It is perhaps most well known from pufferfish (e.g., Brillantes et al. 2003; Lin et al. 1998), but it is also known to occur in the tissues of newts and other amphibians (reviewed in Daly 2004). Among amphibians, the antipredator defensive role of TTX in the rough-skinned newt (*Taricha granulosa*) has been the subject of extensive study (e.g., Brodie et al. 2002; Hanifin et al. 2003; Hanifin et al. 1999; Lehman et al. 2004). Further, TTX was recently found to be retained in the liver of *Thamnophis sirtalis*, which is a natural predator of T. *granulosa* (Williams et al. 2004). The ecology and function of TTX in other amphibian, and potentially reptilian, species is not well known. Further study of *T. granulosa* and other species with TTX would be enhanced with easier extraction and quantification of TTX, particularly if the method is easily implemented. Here I describe a new technique (tissue sonication) for TTX extraction from tissue samples and the use of a quick and efficient indirect competitive-inhibition enzyme immunoassay (CIEIA) to quantify TTX.

TTX extraction protocols have previously used manual grinding of tissue samples in extraction buffer. This extraction method is labor-intensive and slow, not desirable traits for processing a large number of samples. Further, previous methods of identifying and quantifying TTX include gas chromatography-mass spectrometry and high performance liquid chromatography (HPLC; Noguchi and Mahmud 2001). These techniques require highly specialized equipment and training, and can be both expensive and time-consuming. The improvements I report here should make TTX quantification easier and more accessible to researchers with access to standard molecular biology equipment.

TTX Extraction

Some types of tissues are difficult to manually grind, leading to a physically demanding and time consuming extraction process. Manual grinding also requires a relatively large volume of extraction buffer to accommodate the tissue and pestle in the grinding vessel. By employing a tissue sonifier, the time, physical demand and expense associated with extracting TTX can be reduced. To prepare samples for sonication, a small amount of tissue (e.g., a single egg or a skin sample) is placed in a 2 ml microcentrifuge tube with a screw cap. 400 μL of extraction buffer (0.1 M acetic acid) is added to the microcentrifuge tube. In the case of larger amounts of tissue, more extraction buffer (e.g., 800 μL) may be necessary. Each sample is then sonicated for 15–20 seconds, or until the tissue is completely homogenized, using a sonifier (Branson Sonifier 450) fitted with a microtip probe at a power setting of 3 (medium-low). Care must be taken to not touch the probe to the side of the microcentrifuge tube, as this can melt the plastic. To prevent cross-contamination of samples, the sonicator probe should be cleaned with ethanol and water, and then manually wiped, after each sample is sonicated. Based on working with *T. granulosa* skin samples, 16 samples can be sonicated in less than 10 min; manually grinding the same number of samples may take upwards of 2 h. Following sonication, the homogenized samples are heated for 5 min in a boiling water bath or in a 100°C dry heat block, and then cooled to room temperature. The homogenate is then centrifuged at 13000 rpm for 20 min. After centrifugation, the supernatant is removed in 400 μL aliquots and transferred to Millipore centrifugal filter devices (Ultrafree®-MC, 10000 NMWL filter units). The final step in the extraction process is centrifugation at 13000 rpm for 20 min in the filter units. The extract can then be stored at -80°C until needed.

This protocol differs from previously used protocols primarily in the use of a sonifier to extract TTX from tissue instead of manual grinding, saving a large amount of time. Additionally, tissue sonication lowers expenses by reducing the volume of extraction buffer used, which subsequently lowers the number of costly Millipore centrifugal filter devices. Samples extracted using this protocol can be assayed both by indirect CIEIA (below) and HPLC. I have successfully used this method to extract TTX from *T. granulosa* eggs, and skin samples taken from both *T. granulosa* (5 mm diameter piece of skin) and *Notophthalmus viridescens* (3 mm diameter) using a skin punches (Hanifin et al. 2002).

Indirect CIEIA

Direct and indirect CIEIA methodologies have been developed for quantifying TTX (Kawatsu et al. 1997; Raybould et al. 1992). These methodologies differ in their use of a labeled (direct) or unlabeled (indirect) anti-TTX antibody. A labeled antibody is bound to a chromagenic enzyme (e.g., alkaline phosphatase), and the addition of a particular substrate (e.g., p-nitrophenyl phosphate (pNPP)) results in a color change indicating the amount of antibody present. However, only an unlabeled anti-TTX antibody is available commercially (Hawaii Biotech, Inc.), making the indirect (rather than direct) CIEIA is necessary. The method described here (indirect CIEIA) uses an unlabeled anti-TTX antibody and a secondary antibody that is bound to alkaline phosphatase to elicit a color change.

The TTX assay procedure begins by attaching TTX to the wells of a 96-well immunoassay plate. However, TTX does not bind to the surface of a plate because it is such a small molecule; therefore it must first be chemically conjugated to bovine serum albumin (BSA, Sigma, Inc.) with the aid of formaldehyde (F), forming the BSA-TTXF complex. To create the BSA-TTXF, the following ingredients are mixed in an amber glass vial: 700 μL of 1 mg/mL TTX in 1% (v/v) acetic acid, 300 μL 1M sodium acetate buffer (pH 7.4), 179 μL of 33.6 mg/mL bovine serum albumin (BSA) in 1M sodium acetate buffer, and 41 μL 37% formaldehyde. The vial is then sealed and incubated on a shaker at 37°C for 3 days. The solution is then dialyzed against four 1 L changes of phosphate buffered saline (PBS) spaced approximately evenly over 3 days at 4°C. The concentration of BSA in the solution is then determined spectrophotometrically using an extinction coefficient of 0.667 mg·cm/mL at 280 nm, with the spectrophotometer blanked with PBS. The solution can then be stored at 4°C and diluted to 10 μg/mL in PBS as needed for the assay.

The TTX assay procedure is outlined in Table 1. On each plate, a positive and a negative control are run, in addition to TTX stan-

Table 1. Instructions for the indirect CIEIA to measure TTX concentration.

1. Add 100 μL of 10 μg/mL BSA-TTXF, diluted in PBS, to each well of a 96-well microtiter plate (Nunc MaxiSorp).
2. Coat wells by incubating overnight at 4°C or at room temperature for 1 hour.
3. Wash all wells 3 times with 300 μL per well of PBS-T (PBS with 0.5 mL/L Tween-20®).
4. Block each well with 200 μL of 1% BSA in PBS (PBS+BSA) for one hour at room temperature.
5. Wash all wells 3 times with 300 μL per well of PBS-T.
6. Add 50 μL of sample or standard, diluted in PBS+BSA, to their assigned wells.
7. Add 50 μL of anti-TTX antibody, diluted to 2 μg/ml in PBS+BSA, to all wells except positive and negative controls.
8. Incubate plate for 1 hour at room temperature.
9. Wash all wells 3 times with 300 μL per well of PBS-T.
10. Add 100 μL per well of alkaline phosphatase-labeled goat anti-mouse IgG + IgM (H+L) conjugate, diluted in PBS+BSA, to all wells except the positive and negative controls.
11. Incubate for 1 hour at room temperature.
12. Wash all wells 3 times with 300 μL per well of PBS-T.
13. Add 200 μl per well of 1mg/ml pNPP solution.
14. Add 50 μl of goat anti-mouse IgG+IgM to the positive control wells.
15. Incubate at room temperature, protected from light, for 20 min.
16. Determine absorbance of each well at 405 nm.

dards and the samples of unknown TTX concentration. The positive control verifies that the chromagen pNPP (Sigma, Inc.) and secondary antibodies are functional. The negative control verifies that no color change occurs when no secondary antibodies are present. The protocol outlined in Raybould et al. (1992) was followed with the following exceptions: plates were coated with BSA-TTXF overnight at 4°C; plates were blocked with 1% BSA in PBS for 1 hr at room temperature; plates were washed 3 times with PBS-T (PBS with 0.5 mL/L Tween-20®) prior to application of pNPP. The following concentrations or dilutions were used: 10 µg/mL BSA-TTXF diluted in PBS; 2 µg/mL anti-TTX murine monocolonal antibody (Hawaii BioTech, Inc.) diluted in PBS+BSA; 1:4000 dilution of alkaline phosphatase-labeled goat antimouse IgG + IgM (H+L) (Jackson ImmunoResearch, Inc) diluted in PBS+BSA. TTX standards, diluted in 1% BSA in PBS, are used at the following concentrations (ng/mL): 100, 75, 50, 25, 10. After addition of pNPP to the wells, the plate is incubated at room temperature, away from light, for 20 min. The absorbance at 405 nm of each well is then read on a microplate reader. A strong linear relationship between absorbance and the log of the concentration for each standard is found between 10 and 100 ng/mL (Fig. 1). The linear equation from this standard curve is used to calculate the concentration of TTX in all the samples from the absorbance values of the corresponding wells. For accurate results, samples must be diluted into this linear range. The dilution factor used must then be accounted for when calculating the unknown concentrations. There is a negative relationship between absorbance and TTX concentration because this is a competitive inhibition assay—the strongest color change is seen in those wells that contained samples without TTX.

Following the protocol of Raybould et al. (1992) for preparation of a BSA-TTXF conjugate and the indirect CIEIA as described here, one is able to assay 40 samples (in duplicate) per microtiter plate. All samples, standards and controls are run in duplicate (or triplicate, etc.) to allow determination of variation in the readings.

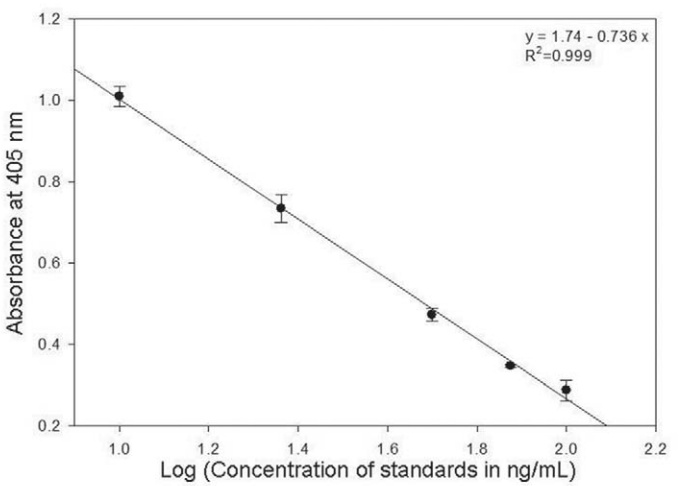

FIG. 1. An example standard curve for the linear portion of the curve (10 to 100 ng/mL). The mean absorbance values (± 2 S.E.) of two wells per concentration are shown. The equation shown in the upper right hand corner is used to calculate the log TTX concentration (x) of samples based on the absorbance value (y) for each well. The log concentration is then converted back into regular units (ng/mL).

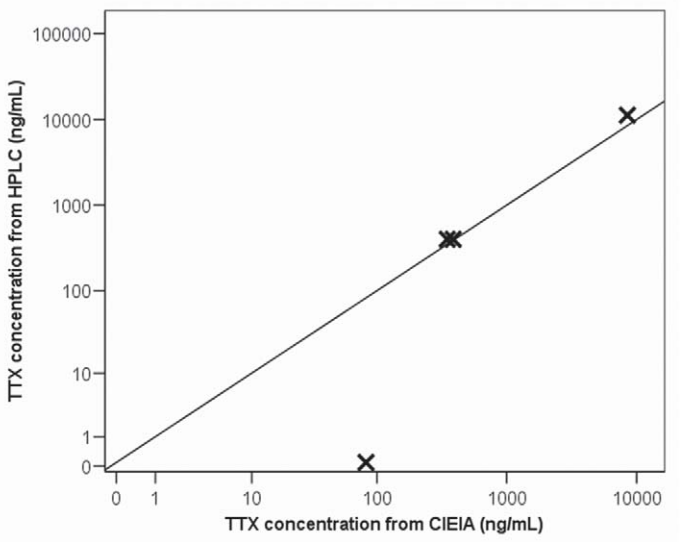

FIG. 2. Concentrations of TTX (ng/mL) in samples assayed by both CIEIA (x-axis) and HPLC (y-axis). These samples (provided by C. T. Hanifin) were from *T. granulosa* skin, extracted using manual tissue grinding and assayed by conventional HPLC techniques (Hanifin et al. 1999). The line is a 1-to-1 line illustrating identical results from CIEIA and HPLC; points fall along the line if both assay methods yield the same concentration.

One plate takes approximately 22 h to complete as described, but this could be reduced to approximately 6 h if the plate is coated with BSA-TTXF for 1 h at room temperature; careful record-keeping allows multiple plates to be run at the same time. Further, plates can be coated with BSA-TTXF and blocked with 1% BSA in PBS in advance, and stored at 4°C for a few days.

Results from this indirect CIEIA method are remarkably similar to those obtained using HPLC (Fig. 2). Samples tested were provided by C. T. Hanifin, from *T. granulosa* skin samples that were manually ground for TTX extraction and assayed using conventional HPLC methods (Hanifin et al. 1999). The primary discrepancy between the two methods is found at a low concentration of TTX, where the indirect CIEIA is more sensitive than HPLC. Samples with high TTX concentrations can be carefully diluted into the appropriate concentration range.

One potential limitation of CIEIA is that it does not allow identification of TTX analogs or structurally similar compounds that can be identified by HPLC (e.g., Yotsu-Yamashita and Mebs 2001). The quantification of TTX by CIEIA should not be affected by TTX analogs because the anti-TTX antibody does not bind to TTX analogs (Raybould et al. 1992), so there is no risk of false positives. Even when TTX analogs are identified by HPLC they are not quantified because the necessary standards are unavailable (C. T. Hanifin, pers. comm.), making this a limitation common to both TTX quantification methods. Thus, CIEIA is appropriate for TTX quantification but inappropriate for identification of TTX analogs that may be present.

Indirect CIEIA, as described here, provides a quantification method for TTX that is not only efficient but also easily employed by any researcher in a university or laboratory setting. No special equipment is needed other than a plate reader capable of reading at 405 nm, and plate washer for more efficient washing between

steps. The collective cost of this equipment is well below the cost of that needed to quantify TTX via HPLC. Further, individuals do not need much training to perform the indirect CIEIA because only general laboratory protocols (e.g., use of a pipette) and common reagents are used. It should be noted that particular care must be taken in the handling of samples and disposal of TTX waste, as is required for any TTX use. Implementation of the TTX extraction and assay procedures may require institutional approval.

Acknowledgments.—Greg Demas and Amy Eklund helped get the indirect CIEIA working. Greg Demas was also very generous in letting me use the sonifier, plate washer and plate reader in his lab. Charles Hanifin provided samples which had previously been assayed via HPLC. Funding was provided by the National Science Foundation to Edmund D. Brodie III (NSF DEB-9908829 and DEB-0316004). This research was conducted in compliance with Indiana University Biosafety Protocol #04-003 and Bloomington Institutional Care and Use Protocol #05-084.

Salamander skin secretions are effective defenses against both vertebrate and invertebrate predators (Arnold 1982; Barach 1951; Brodie 1983; Brodie et al. 1979; Digiovanni and Brodie 1981; Ducey and Brodie 1983; Pough 1971; Rand 1954). These secretions arise from granular glands located on the skin's surface (Brodie and Gibson 1969) and are generally a combination of adhesive compounds and noxious chemicals that act in a synergistic manner with stereotypical behaviors to effectively protect the salamander from predation (Brodie 1977). This combination of adhesiveness and noxiousness is often seen in the ambystomatid salamanders, which are known for their distinctive antipredator postures (Brodie 1977, 1983). Although the granular gland secretions of ambystomatids are distasteful to humans (Brodie 1983), shrews (Brodie et al.,1979), moles (Anderson 1963), and Sprague-Dawley rats (Mason et al. 1982), we know little about the chemical composition of their defensive secretions (Williams and Anthony 1994).

Research on the nature of granular gland chemistry has been extensively investigated in anurans (Clarke 1997; Daly 1998; Daly et al. 1987), but is notably sparse among urodeles (Brodie 1983; Williams and Anthony 1994) with a few exceptions (Brandon and Huheey 1981; Buchwald et al. 1964; Habermehl 1971). The adhesive nature of ambystomatid secretions often thwarts chemical investigations of granular gland secretions, and this has stymied secretion chemistry from progressing beyond the identification of proteinaceous material (Brodie and Gibson 1969; Hamning et al. 2000; Williams and Anthony 1994). Flocculence from adhesive components presents a challenge to further isolation of active compounds, and has hampered the testing of solutions at known concentrations (Hamning et al. 2000; Williams and Anthony 1994). Characterization and identification of the chemicals in granular gland secretions of salamanders may enable a deeper understanding of their evolutionary relationships as well as the evolution of salamander antipredator mechanisms. Therefore, we developed methods to (i) isolate adhesive-free secretion from ambystomatid

salamanders, and (ii) assay distastefulness of known concentrations of this secretion. This technique allows us to differentiate between the adhesive and noxious effects of salamander skin secretions against a reliable and consistent control.

We used three adult Jefferson's Salamanders (*Ambystoma jeffersonianum*), collected in Tompkins County, New York in 2000, five Spotted Salamanders (*A. maculatum*), collected in Tompkins County, New York and four near St. Louis, Missouri in 2000, and three Tiger Salamanders (*A. tigrinum*) collected near Portal, Arizona in 2000.

Salamanders were housed in clear plastic boxes (10 cm tall × 40 cm long × 20 cm wide) and provided with inverted black plastic food trays for shelter, and a substrate of moist paper towels. *A. tigrinum* specimens were part of a captive population that was fed crickets *ad libitum* once every two weeks during the duration of their captivity. Their secretions were collected at approximately six months into captivity. Although other amphibians obtain their defensive compounds from the diet (Daly et al. 1997a; Daly et al. 1997b), we did not expect this to have a significant effect on ambystomatid secretion composition because their secretions are proteinaceous (Williams and Anthony 1994). Peptides and proteins are generally produced endogenously and not derived from the diet (Apponyi et al. 2004). *A. jeffersonianum* and *A. maculatum* were locally collected during the breeding season, held overnight, sampled the next morning, and released within 24 h. Mean weight (± standard deviation) of salamanders was 6.3 ± 4.3 g (SVL: 5.5 ± 1.1 cm) for the *A. jeffersonianum*, 13.0 ± 4.3 g (SVL: 7.8 ± 1.3 cm) for the *A. maculatum*, and 49.0 ± 1.0 g (SVL: 12.5 ± 0.5 cm) for the *A. tigrinum*. All animals maintained or gained weight during captivity; no unhealthy salamanders were used in the study. Salamanders were not sexed because sexual dimorphism has yet to be described in the defensive chemistry of any amphibian.

As our predator we used Red Swamp Crayfish (*Procambarus clarkia*) obtained from Carolina Biological Supply Company (Burlington, North Carolina) and kept in plastic ice-chests. They were fed carrots and dry dog or cat food pellets *ad libitum* approximately twice per week. Mean weight (± standard deviation) of the twenty crayfish was 28.5 ± 6.3 g. Although they do not likely prey upon adult ambystomatids, crayfish are predators of many larval amphibians (Axelsson et al. 1997; Formanowicz and Brodie 1982; Gamradt and Kats 1996; Gamradt et al. 1997; Holomuzki 1989) and potentially might attack recent metamorphs that possess defensive glands. Furthermore, crayfish possess traits that make them good generalized predators for laboratory studies: they are omnivorous and use chemical cues to locate food (Dunham et al. 1997).

We collected crude secretions from individual salamanders by applying a benign electrical stimulus to the skin (Grant and Land 2002; Hamning et al. 2000; Tyler et al. 1992; Williams and Anthony 1994). We used a Transcutaneous Amphibian Stimulator (TAS) developed by Grant and Land (2002) to deliver the electrical stimulus, which ranged from 10 to 15 V pulsed for 2 msec at a frequency of approximately 50 Hz. We focused our collection efforts on the tail ridge of all species (Fig. 1) because it and the parotoid glands on the head contain the richest secretions (Williams and Larsen 1986). Before stimulation each salamander was lightly moistened with distilled water to facilitate transmission of the stimulus. Secretions were washed off the skin with approximately 50 ml distilled water and funneled into a flask.

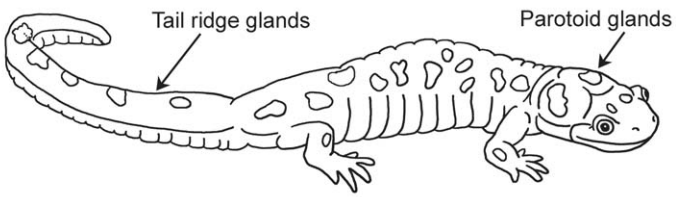

FIG. 1. Granular gland rich areas of a typical ambystomatid salamander (parotoid glands on head and areas of the tail ridge) are indicated with arrows. Illustrated by JBG.

Amphibian skin secretions consist of four major groups: biogenic amines, bufogenines and bufotoxins, alkaloids, and peptides and proteins (reviewed in Barthalmus 1994; Clarke 1997; Daly and Witkop 1971; Erspamer 1984, 1994). Preliminary high performance liquid chromatography (HPLC) data suggested that peptides and a *N*,*N*-dimethyl homolog of serotonin, bufotenine, were the major compounds in the secretion (Grant, unpubl. data). Because bufotenine and many amphibian skin secretion peptides are soluble in both water and methanol (Brodie and Gibson 1969; Daly et al. 1987; Erspamer 1984, 1994; Hamning et al. 2000; Mason et al. 1982; Williams and Anthony 1994), these were chosen as extraction solvents.

Crude aqueous extracts were filtered through glass wool to remove adhesive components of the secretion because they prevent proper measurement of the concentration of active components (Brodie and Gibson 1969). This aqueous solution was lyophilized (freeze-dried) to remove water and any remaining traces of adhesive compounds. The dried residue was washed twice with methanol then filtered through glass wool to remove suspended particulates, which were assumed to primarily consist of inactive adhesive flocculent. The methanolic extract was dried under nitrogen to obtain the residual weight of adhesive-free secretion obtained from each salamander. All solvent-free samples were stored in Teflon-lined vials at 0°C until use, at which time adhesive-free secretion from all fourteen salamanders was pooled to provide an adequate amount of material for testing during these pilot studies. The combination of secretion at this stage did not effect the extraction methods because we performed it post-extraction.

We used a modified method of Lindquist (1992) to make agar pellets suitable for testing feeding responses of the crayfish. Pellets consisted of water, agar, a crayfish feeding stimulant (0.25 g Fancy Feast™ salmon cat food mixed with 5 mL water then filtered through cheesecloth), and food coloring (green or blue). Control pellets were made by boiling 5 mL of water with 0.10 g of agar until the agar dissolved completely. Five ml of feeding stimulant solution plus one drop of blue food coloring were added to the hot agar solution to make a total of 10 ml. This solution was cooled to between 40°C and 45°C and immediately pipetted into prepared PVC molds (described below). The solution was cooled prior to pipetting into PVC molds to prevent leakage from under the PVC mold. Treated pellets were made by boiling 5 mL of water with 0.10 g of agar until the agar dissolved completely. Five ml of 9.6 mg/ml aqueous adhesive-free extract (AFS) were mixed with 0.25 g feeding stimulant then added to 5 mL of 45°C agar solution and one drop of green food coloring to make a total of 10

ml. This solution was mixed well and pipetted into prepared PVC molds where it solidified (described below). This preparation resulted in 10 ml of agar solution at a concentration of 4.8 mg/ml adhesive-free extract. Crayfish are essentially green blind (Crandall and Cronin 1997; Wald 1968) and did not demonstrate a color preference for either blue or green dyed pellets in our preliminary trials (unpubl. data, 1 h trials, blue pellet remaining wt. = 0.12 g ± 0.02 g; green pellet remaining wt. = 0.11 g ± 0.02 g; Wilcoxon rank sum test: N = 12, *Z* = -0.5449, P = 0.59). Therefore, we dyed all control pellets blue, and all treated pellets green in the secretion assays.

Pellet molds were made by cutting polyvinyl chloride (PVC) pipe (6.35 mm inner diameter) into 8-mm long sections with a band saw. The ends of the sections were filed to clean, flat edges. Dark gray, 7.62 cm × 7.62 cm PVC squares were used to anchor two circles (6.35 mm diameter) of adhesive backed, hook end Velcro® 7.5 cm apart along the diagonal of the square (Fig. 2). These Velcro® circles fit snugly into the piece of PVC molding and prevented semi-cooled agar solution from leaking out during the solidification process.

Pellet molds were filled with either treated (green) or untreated (blue) agar solution until a dome formed on top of the mold. Pellets were cooled for 20 minutes at room temperature until the agar solution solidified. Excess agar was cut off with a razor blade flush against the PVC mold surface. The PVC molds were carefully lifted off the agar pellets, which were retained in place by the Velcro® circles. Each 8 mm high agar pellet had an approximate volume of 0.25 mL and treated pellets contained 1.2 mg of adhesive-free extract.

Because pellets were molded onto Velcro®, we could not obtain their weight prior to a trial. Therefore, we made 40 untreated pellets (20 green, 20 blue), and sliced them off their Velcro® bases to determine the approximate weight of an intact, uneaten pellet. There was no bias in pellet weight between pellets dyed blue (0.21 g ± 0.003 g, N = 20) and those dyed green (0.21 g ± 0.003 g, N = 20; Wilcoxon rank sum test: N = 20, *Z* = -0.5873, P = 0.56). Therefore, these two dyes were used in all further assays and pellets that weighed less than 0.20 g after crayfish trials were considered to have been sampled by crayfish.

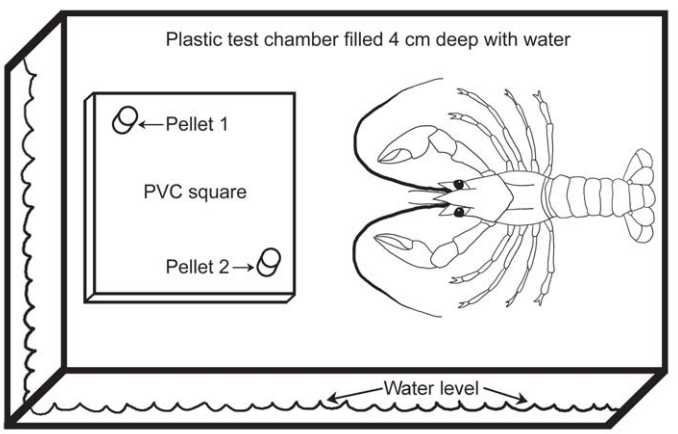

FIG. 2. Schematic representation of the experimental setup. (A) Pellet delivery system consisting of a PVC square with two Velcro® circles. (B) Bioassay chamber used to test crayfish response to treated and untreated pellets. Illustrated by JAE.

We developed a bioassay to determine if crayfish were repelled by AFS. Twenty crayfish were placed in 20 separate plastic containers (9.5 cm tall × 18.5 cm long × 13.0 cm wide) filled with water to a depth of 3 cm. Each crayfish was offered a plastic square to which control and treated pellets were affixed. Squares were placed in the test chamber such that pellet location was randomized with respect to the crayfish, which were allowed to feed for 4 h. Crayfish were prevented from seeing neighboring crayfish during assays. After 4 h we removed the crayfish, sliced pellets off their Velcro® bases with a razor blade, and blotted them dry. Pellets left longer than 5 h began to lose their color, which prevented their identification in cases where crayfish dislodged the pellet from its Velcro® base. All pellets were weighed to the nearest 0.01 g. Trials in which a crayfish did not consume any of either type of pellet were not considered for analysis. Crayfish activity during assays occasionally knocked pellets from the Velcro® base; this necessitated the marking of pellets with treatment-specific dye.

Six of 20 crayfish in the secretion deterrence assay did not eat either type of pellet and were removed from analysis. At 1.2 mg/pellet, adhesive-free salamander skin secretion deterred crayfish feeding as evidenced by a lower remaining pellet weight in control pellets (0.01 g ± 0.01 g, N = 14) than in treated pellets (0.05 g ± 0.02 g, N = 14; two-tailed permutation test for paired replicates: N = 14, P = 0.01). Crayfish avidly ate control pellets and generally avoided treated pellets until nearly all of the control pellet was eaten.

Our methods represent the first and most crucial step in development of a bioassay-guided fractionation scheme necessary to isolate and identify the active chemical compounds of amphibian defensive skin secretions. Bioassay-guided fractionation is an important tool in the identification and chemical characterization of natural chemical products (Debont et al. 1996; Ohta et al. 2000) and will be important in the chemical identification of active components in adhesive-free salamander secretions. Despite over 50 years of research on amphibian skin compounds, very few salamander skin compounds have been identified (Erspamer 1984).

Our approach confirms the antifeedant (*sensu* Eisner et al. 1981) properties of ambystomatid adhesive-free secretion and provides an improved method for quantitatively assaying the effects of salamander skin secretions in general. Brodie et al. (1979) measured predator response after they were offered palatable or unpalatable species. Our approach overcomes difficulties associated with the use of a separate species as the control, and removes the effect of salamander behavior from the effect of secretion. Other research tested aqueous volume/volume secretion solutions of unknown concentrations (Hamning et al. 2000; Mason et al. 1982). Our method eliminates the adhesive components that hamper reproducibility across test subjects due to individual variation among salamanders (Hamning et al. 2000) and loss of secretion as salamander glands are "milked" (Digiovanni and Brodie 1981). Because we pooled secretions from three species, we can not definitively say to which species crayfish were responding. Pooling of secretions from multiple species may cause confounding effects related to synergy among interspecific compounds. This is not expected to diminish the general utility of the method because crayfish response was robust. Our method is generally applicable

to most salamanders and will be useful for future studies on the distastefulness of secretion or assay-guided isolation of secretion components.

Acknowledgments.—We thank Thomas Eisner and Paul Feeny for support and advice, Kelly Zamudio and Christine Voyer for access to and care of salamanders, Kristin D'Aco and Joyce Tibbet for assistance with secretion collection, and several salamander donors. Funding was provided by a Sigma Xi Grant in Aid of Research (JBG). This work was approved under IACUC Protocol #0022 at Cornell University.

Mark-recapture studies are an important and sometimes essential means for developing a detailed understanding of all aspects of amphibian natural history. Toe-clipping has historically been regarded as the most appropriate marking technique for use in many anuran population surveys and ecological research. Unique combinations of multiple digits are removed from the hands and/or feet when the animal is first captured, to allow recognition of each individual (see Donnelly et al. 1994 for a summary). Bogert (1947) first described the procedure, and it has subsequently allowed some individuals to be followed for more than 34 years (Bell and Pledger 2005).

Often toe-clipping has involved amputation above the toe base or webbing (Clarke 1972; Davis and Ovaska 2001; Funk et al. 2003; Lemckert 1996; Reaser and Dexter 1996; Waichman 1992). Current practice by authors Phillott, Skerratt, McDonald and Alford is to remove the toe pad/disc only from a hylid digit or the most distal phalanx from a non-hylid digit. This procedure is more accurately defined as "toe-tipping" rather than "toe-clipping", as there is a substantial distinction between the length of the digit removed. Frequent surveys can rely on toe-tipping rather than toe-clipping as a reliable means of identifying individuals with minimal tissue regrowth (Lüddecke and Amézquita 1999).

Recently, the appropriateness of toe-clipping frogs has been called into question (Funk et al. 2005; May 2004) when studies by Parris and McCarthy (2001) and McCarthy and Parris (2004) predicted decreased recapture rates following toe-clipping. This was considered due either to mortality arising from digit/limb inflammation and infection (see Golay and Durrer 1994; Lemckert 1996; Reaser and Dexter 1996; Williamson and Bull 1996), disturbance resulting in movement of animals away from the study site, or inability to recapture marked animals. Although Parris and McCarthy (2001) and McCarthy and Parris (2004) only used statistical models to project the effect of toe-clipping on amphibian recapture rates and did not conduct studies to quantify this potential effect, these predictions brought into question the scientific validity and ethical status of toe-clipping (e.g., May 2004) and have led some research and government organizations to refuse permission to use this method. However, there has been little consideration given to the impacts of alternative methods of marking anurans (Funk et al. 2005), no real discussion of how these impacts occur and if they may be overcome, and no assessment of the necessity of toe-clipping for carrying out ecological research that may be critical for species conservation.

The actual reasons for the reduced return rates after toe-clipping described by Parris and McCarthy (2001) and McCarthy and Parris (2004) need to be further explored. Reductions in survival rates (due to infection or limited mobility leading to starvation or increased predation risk) and recapture rates may both contribute to reduced return rates. Actual increases in mortality as a result of toe-tipping or -clipping have not been directly measured, and the validity of the assumption that this is the only factor affecting recapture rates following toe-clipping is questionable. Behavioral changes of several types could lead to decreased recapture rates following toe-clipping. Animals could alter activity patterns or locations within their home ranges, decreasing the probability of recapture. The degree of site fidelity of many amphibians is unknown, and at least some are known to be nomadic (Schwarzkopf and Alford 2002). If toe-clipping increases the probability of animals moving away from the location at which it occurred, it will appear to reduce survival, since survival and emigration rates are very difficult to separate using mark-recapture techniques. Distinguishing the mechanisms responsible for changes in recapture probability following the application of toe-clipping and other marking techniques should be a priority subject for future research.

Even if increased mortality is the cause of decreased returns, it is possible that these increases can be minimized through a more considered approach to toe-clipping. Frequent surveys can rely on toe-tipping rather than toe-clipping as a reliable means of identifying individuals with slow or no tissue regrowth. It has long been

TABLE 1. Alternative marking techniques to toe-clipping/tipping.

Marking Procedure	Advantages	Disadvantages
PIT (Passive Integrated Transponder) Tags	Should not effect mobility[1]	Invasive Requires extensive handling, anaesthesia and recovery[1] Potentially suitable for inducing foreign body tumorigenesis[2] Tags can migrate or be lost[1] Cannot be applied to small frogs[1]
VIE (Visible Implant Elastomer) Tags	Relatively inexpensize[3] Should not effect mobility[4]	Invasive Can be difficult to visualise[3] Requires extensive handling and anaesthesia[3,4] Easiest when amphibians tagged in groups[4]
VIA (Visible Implant Alphanumeric) Tags	Relatively inexpensive Should not effect mobility[4]	Invasive Requires extensive handling, anaesthesia and recovery time[3] Tags can migrate[3] Can be lost[3] Can be difficult to visualise[3]
External Radio Transmitter	Non-invasive Allows researcher to find location of individual[5,6,7]	Normal movements and behaviour may be hindered[5] Skin lesions can occur[6] Restricted to medium to large amphibians[5] Time consuming[5] Limited battery life[5] Expensive[5] Tags can be lost[6]
Internal Radio Transmitter	Allows researcher to find location of individual[5]	Invasive Time consuming[5] Requires extensive handling, anaesthesia and recovery time[6,7] Tags can migrate[8] Tags can be lost[6]
Pattern Mapping	Non-invasive Can be applied to small animals[9]	Limited application due to lack of or limited patterns in many species[10] Temporal inconsistency of patterns in suitable species[9,11] Time consuming[9]
Pressurized Fluorescent Marking	Tagged amphibians do not require capture to identify[12]	Invasive Only reliable for few weeks[12] Can result in immediate mortality [12] Equipment heavy[12]

[1]Lane 2005a, [2]Vogelnest et al. 1997, [3]Nauwelaerts et al. 2000, [4]Lane 2005b, [5]Richards et al. 1994, [6]Werner 1991, [7]Weick et al. 2005, [8]Gray et al. 2005, [9]Donnelly et al. 1994, [10]Lemckert and Shine 1993, [11]Reaser 1995, [12]Schlaepfer 1998

recognized that toe-clipping could negatively affect anurans, and there are current guidelines for amphibian toe-clipping that provide guidance regarding how best to undertake these procedures (e.g., Herpetological Animal Care and Use Committee HACC [2004] and National Wildlife Health Centre NWHC [2001]). Some of the studies reviewed by Parris and McCarthy (2001) and McCarthy and Parris (2004) did not use, or at least did not report, the use of aseptic techniques such as those recommended by the National Wildlife Health Centre (2001) and NSW National Parks and Wildlife Service (2001). These recommend the use of single-use gloves, sterilized stainless steel scissors, and application of the antiseptic Bactine® to minimize infection (though the latter may not be effective for some species such as stream dwelling frogs that immediately wash off the antiseptic when they return to the water after capture). Higher infection rates are likely to occur if unsterilized instruments are used, and diseases may be transferred between multiple individuals if equipment and handling surfaces are not disinfected. The prevention of contamination and infection should be a primary concern in studies using any tagging technique, and toe-tipping/clipping is less likely to result in infection if the above standards are followed.

Alternatively, some increased mortality may result from a loss of mobility due to the loss of toes. This aspect does not appear to have been explored, and we recommend that controlled studies should be undertaken to compare the mobility and survival of clipped versus unclipped frogs. However, even given this lack of

knowledge, steps can be taken to minimize any possible effects on mobility. The effect of toe-tipping/clipping on populations can be minimized by careful consideration of frog activities. Species heavily reliant on toes (e.g., arboreal or burrowing species) should be given a minimal number of clips. Removal of the toe pad only, instead of the entire toe, still allows a reliable means of recognition. It is already recommended that toes essential for burrowing, climbing, amplexus or nest excavation should not be not removed (HACC 2004).

May (2004) describes the practice of toe-clipping as "casually barbaric." The relative pain of toe-tipping/clipping has not been assessed or compared with alternative marking procedures. We have rarely observed a clinical pain response after toe-pad removal. While invasive procedures should not be applied without due consideration of the pain and stress caused to the animal, it must be remembered that mammals have a greater capacity to perceive pain than do other vertebrates (Stevens 1992). Toe-tipping/clipping amphibians cannot be considered as causing the equivalent distress and pain as digit amputation in a human or other mammal. We acknowledge that amphibians are able to perceive pain, however we regard the use of anaesthetics, analgesics and sedatives as far more likely to negatively affect an amphibian's homeostasis because it may be difficult to localize effects of applications of chemicals associated with toe-clipping. No single anaesthetic is effective for all amphibians due to their species-specific responses (Fellers et al. 1994) so their use can be both difficult and harmful. Chemical intervention during minor procedures increases handling and recovery time, and is thus likely to impose further stress on animals. In addition, the HACC (2004) regards pain as an adaptive response that reduces the use of an injured limb during recovery, and describes the use of anaesthetics in procedures such as toe-clipping as undesirable. This reduces handling time and allows post-operative, field-released animals to adapt their activity to compensate for the affected limb/s.

While toe-tipping/clipping is the least expensive of the marking procedures suitable for amphibians, the decision to use this method should not be based on cost alone. We believe that toe-tipping/clipping is fast, reliable, and toe-tipping possibly the least stressful marking method for anurans. Furthermore, we note that in many countries, toe-tipping/clipping cannot occur without the approval of animal ethics committees at research institutions.

In recent times a range of alternative techniques have been proposed as suitable means to mark individuals over extended periods. Proponents of alternatives (e.g., May 2004) have provided no evaluation of impacts of the procedures on marked individuals. The only entirely non-invasive technique successfully used to identify individual anurans is pattern mapping by photograph or sketch. Alternative invasive techniques to toe clipping or toe tipping have included dye markers (e.g., Visible Implant Elastomer [VIE] tags and pressurised fluorescent marking techniques), individual recognition tags (e.g., Visible Implant Alphanumeric [VIA] Tags and Passive Integrated Transponder [PIT] tags), radio telemetry transmitters, and branding (using tattoos, silver nitrate, heat, or freezing). The advantages and disadvantages of all procedures are summarised in Table 1. It is clear that all marking techniques carry risks and may have adverse effects on marked animals, so all techniques violate assumptions related to population estimation models. However, more study is required to determine which techniques have the least adverse effects.

All invasive marking techniques have ethical considerations. The value of the work to the species as a whole should be weighed against the potential impacts on individuals. The stress imposed on a limited number of individuals needs to be balanced against the increased knowledge that can be gained for the species. Management plans must be based on an understanding of the natural history of the animal, including site fidelity, home range and longevity, and factors such as disease, which affect survival. Assured recognition of individuals is essential to determine such parameters.

As extinctions of frog species occur with the global emergence of chytridiomycosis, threatened and potentially-threatened populations must be studied to understand the epidemiology of this disease. Prevalence, incidence, survival and transmission rates cannot be calculated without absolute certainty of individual recognition. In the absence of another widely applicable tagging technique, known to have at most small effects on return rates, we suggest that toe-clipping is the only feasible option that can be applied to many species and to all post-metamorph members of a community. Additional research is urgently needed to evaluate the impacts of all marking techniques, and to develop new ones with lower impacts. Until this has been done, we believe that it is more ethical to use toe-clipping in studies aimed at understanding and preventing further loss of anuran diversity than it would be to stand by, leaving many species unstudied, or to use alternative techniques that have not been studied and which may have greater impacts on amphibians.

Non-Contact Infrared Thermometers Can Accurately Measure Amphibian Body Temperatures

JODI J. L. ROWLEY

Body temperature affects almost all biochemical and physiological processes in ectothermic organisms (Hutchinson and Dupré 1992), and thus affects movement, habitat selection and thermoregulatory behavior (Bartelt and Peterson 2005). A variety of devices have been used to determine the body temperatures of amphibians in the field. The most typical is a thermocouple probe connected to a quick-reading thermometer, which has been used to measure skin (Brattstrom 1963; Heath 1975; Lillywhite 1970; Navas 1996; Tracy 1976), oral (Brattstrom 1963; Lillywhite et al. 1973; Lillywhite et al. 1998), or cloacal (Brattstrom 1963; Cabanac and Cabanac 2004; John-Alder et al. 1988; Passmore and Malherbe 1985; Thorson 1955; Vences et al. 2002) temperature. These methods require manual handling of each individual, which may artificially elevate its body temperature (due to conduction; Navas and Araujo 2000), or may alter the behaviour of individuals in studies of a longer duration (i.e., by capture stress).

To date, non-invasive methods of measuring amphibian body temperature that do not require the manual handling of individuals have included the attachment of thermally sensitive radio-transmitters (Bradford 1984; Heath 1975; Seebacher and Alford 2002) and the use of physical models (Bartelt and Peterson 2005; Hasegawa et al. 2005; Navas and Araujo 2000; O'Connor and Tracy 1987; Seebacher and Alford 2002). More recently, an additional method of measuring amphibian body temperature has become available, via the use of hand-held, non-contact, infrared thermometers (e.g., Young et al. 2005). These thermometers have been widely adopted in the medical sciences, and have been shown to accurately measure body temperature in humans (Koçak et al. 1999; Rotello et al. 1996; Terndrup et al. 1997). Despite their promise as a rapid, non-invasive method of measuring amphibian body temperature, their accuracy for measuring amphibian body temperature has not been quantified. We designed this study to determine whether a non-contact infrared thermometer can be used to accurately measure the body temperatures of amphibians.

Materials and Methods.—Our experiment was designed to allow us to measure body temperatures of frogs allowed to experience a wide range of thermal environments in a laboratory setting. We set up three opaque plastic containers (60 cm × 40 cm × 40 cm), each with a small water bowl in the center and a metal fly-screen lid. The containers were housed in a constant temperature room, which maintained ambient temperature between 19.5 and 21.5°C. Relative humidity fluctuated between 64 and 96% (mean 74%). A 150-watt heat lamp was provided at one end of the container during the day (0930–2130 h) in order to provide a heat gradient within

the normal temperature range of the species.

Twelve adult Common Green or White's Tree Frogs (*Litoria caerulea*) were captured near Townsville, Queensland, Australia. They ranged from 74.1–91.8 mm SVL and 26–65 g body mass. Prior to experiments, they were maintained in the constant temperature room in which the experiments were carried out, but in smaller containers with no access to heat lamps. Frogs were fed crickets *ad libitum*. Each frog was used in a single run of the experiment. We ran four temporal replicates of the experiment, creating a total of twelve sets of measurements of frog and model temperatures for comparison. Each replicate ran for three days.

Body temperatures of frogs were recorded five times per day (0900, 1100, 1300, 1500, and 1700 h), producing 15 measurements for each of the 12 frogs. The first time (0900 h) was chosen because at that time the frogs had received no source of heat for almost 12 h, and their body temperature should have been similar to a nocturnal reading in the field. Each run of the experiment was set up at least 60 minutes before the first temperature reading was taken, allowing frogs to reach a thermal steady state.

At each reading, frog body temperature was recorded using three techniques. Firstly, temperature was recorded by holding a Raytek ST80 Pro-Plus Non-contact thermometer (RAYST80; "IR thermometer") approximately 5 cm away from the frog and aiming at the lower dorsal area near the thigh. The model of IR thermometer used in this study had a distance to spot ratio of 50:1, and the area measured is delineated by a circle of laser diodes. Emissivity was set on the IR thermometer at 0.95, as it is generally accepted that amphibians have a long-wave emissivity of approximately 0.95–0.97 (Carroll et al. 2005; Tracy 1976), regardless of their color (Nussear et al. 2000; Tracy 1979). In initial trials, we determined that measured frog body temperatures did not vary by more than 0.1°C when the emissivity setting of the IR thermometer was varied between 0.95–1.0.

After taking a reading using the IR thermometer, we then measured skin and cloacal temperatures (in that order) using a small, chromel-alumel "K" type thermocouple (diameter approx. 1 mm) with the tip coated in plastic, attached to a digital thermometer type 90000. To measure skin temperature, the thermocouple was held firmly against the skin on the lower dorsal area near the thigh while the frog remained in its original position in the container. During cloacal temperature measurement, each frog was held by a single leg, while still in the container, and the thermocouple was inserted 10–20 mm inside the cloaca and the reading was taken when the indicated temperature stablized.

Frogs were usually in the water conserving posture immediately prior to temperature measurement, except for several instances at 0900 h. It is probable that there are small differences among individual frogs, related to body size or individual behaviour, that affect how temperatures measured using the three techniques are correlated, so that the measurements for each individual frog are not entirely statistically independent. We therefore did not carry out any hypothesis tests, but concentrated on modelling the relationships between measurements taken using the three techniques, and determining how well our models fit the data. Because all three variables are measured with error, we constructed models of their relationships using major axis regression (Sokal and Rohlf 1995). We determined how well our regression models fit the data by calculating coefficients of determination, using standard correlation analysis.

Room temperatures were recorded every 30 minutes using thermal data loggers (Thermochron iButtons by Dallas Semicondictor, Dallas, Texas USA). Data loggers and thermocouples were calibrated against a high precision mercury thermometer in a magnetically stirred water bath.

Results.—Body temperatures measured using the IR thermometer and both skin and cloacal temperatures measured using the thermocouple probe were highly correlated. The major-axis regression lines relating each type of temperature measurement to the others were all very similar to the line of equality (Fig. 1). The major-axis regression lines never predict a mean difference greater than approximately 0.5°C between any two temperatures in the range of 18–34°C for any pair of measurements.

Discussion.—The surface of basking animals may reach slightly higher temperatures faster and decrease more rapidly after basking ceases than the body core (Remmert 1985). However, we found that skin temperatures measured either by contact thermocouple or IR thermometer were almost always within 0.5°C of cloacal temperatures (Fig. 1); this appears to be relatively common in small ectotherms such as frogs (Wygoda 1984), and other small ectotherms such as lizards (<10–20 g; Jones and Avery 1989). It is likely that the small number of points which depart to a larger-than-usual extent from the lines of equality and regression lines in Fig. 1 were measured on animals that had recently changed from basking to non-basking or the reverse.

We found that cloacal temperature was slightly better predicted by surface temperature as measured by the IR thermometer than it was by skin temperature measured using a thermocouple. This indicates that surface temperatures measured using the IR thermometer should provide accurate indicators of internal body temperatures in most amphibians.

Good quality IR thermometers have long-range optical resolution, allowing measurement of small targets at long distances. As the distance from the object increases, the spot size of the area measured by the unit becomes larger. Therefore, the smaller the target, the closer you must be to it in order to avoid measuring a combination of amphibian and background temperatures. Especially in the field, it is necessary to take the distance to spot ratio into account. When studying small frogs, it may only be possible to measure temperatures at short ranges (< 0.5 m). As the laser is located above the sensor in many models, it is also important to take parallax effects into account when aiming the sensor, as at near distances the point of aim of the sensor will be displaced from the point of aim of the laser diode.

It is likely that IR thermometers will be useful in measuring other small animals, such as reptiles, in the field. As all plants and animals act almost as black-bodies in the middle infrared (Sustare 1979), having an emissivity nearing 1.0, no major changes in the technique will be necessary when used on different species. Indeed, we are presently using IR thermometers successfully for measuring the body temperatures of a number of amphibian species in the field (Rowley and Alford, unpubl. data).

We have shown that non-contact infrared thermometers can be used to accurately determine the body temperatures of amphibians. Benefits of this technique include relatively low cost (approximately US $340), small size and therefore high portability, and the ability to rapidly record the temperature of a large number

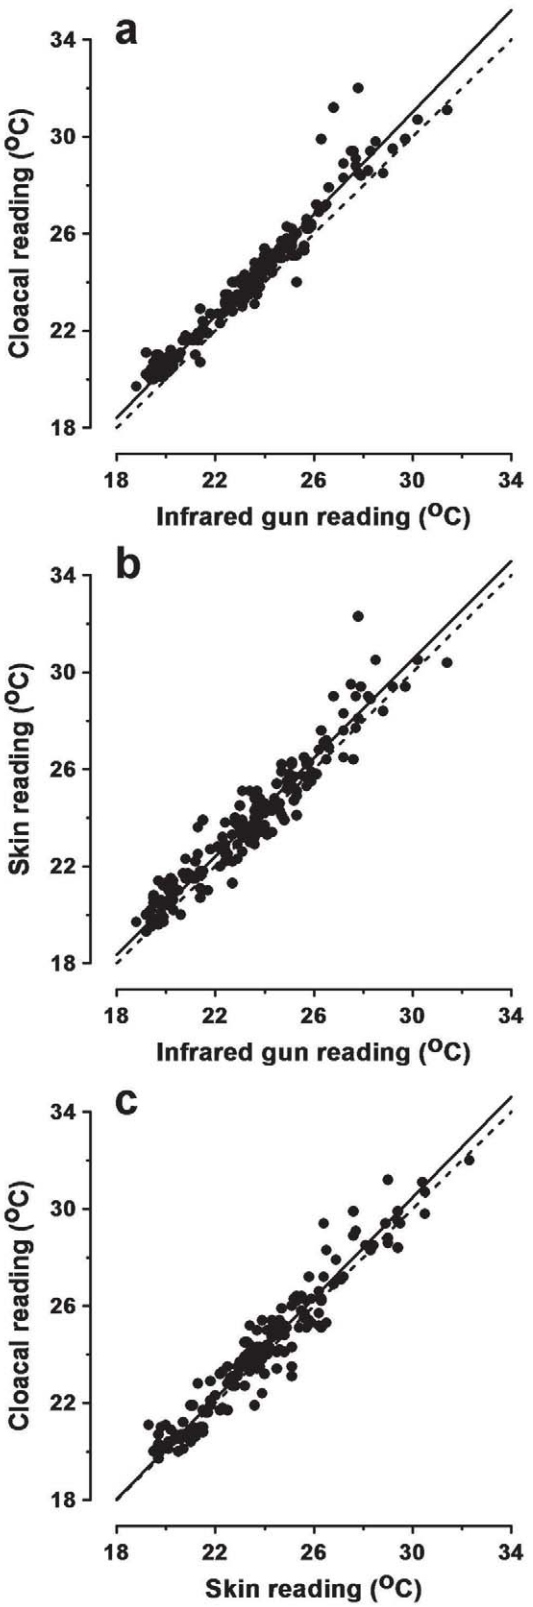

FIG. 1. (a) Measured cloacal temperature as a function of infrared gun reading. Dashed line is at y = x, solid line is the major axis regression $y = 1.052x - 0.535$ with $r^2 = 0.949$. (b) Measured skin temperature as a function of infrared gun reading. Dashed line is at y = x, solid line is the major axis regression $y = 1.014x + 0.1049$, with $r^2 = 0.922$. (c) Measured cloacal temperature as a function of skin temperature. Dashed line is at y = x, solid line is the major axis regression $y = 1.038x - 0.657$, with $r^2 = 0.932$.

of individuals. Perhaps the most important feature of the technique, however, is its ability to record the temperature of amphibians without handling them. This reduces disturbance, which can be important when the same individual is to be measured repeatedly, or when disturbance may cause an animal to abandon a retreat or basking site, exposing it to increased risks of predation or desiccation. In addition, such non-invasive methods of determining amphibian body temperature are likely to be increasingly important due to the need to minimise handling stress and the possibility of disease transmission, particularly when studying species of conservation concern.

Acknowledgments.—This research was supported by funding from the Australian Department of Environment and Heritage, Australian Geographic, a subcontract to R.A.A. from US NSF IRCEB grant DEB-0213851 (J. P. Collins, P.I.), the Society for the Study of Amphibian and Reptiles Grants in Herpetology and the Peter Rankin Trust Fund for Herpetology. JJLR was supported by an Australian Postgraduate Research Scholarship. This study was carried out under Scientific Purposes Permit issued by the Queensland Parks and Wildlife Service (WISP01715204) as approved by the James Cook University Animal Care and Ethics Committee (A955).

Measurement of cloacal temperature using a thermocouple (TC) is a standard and long-established method for determining body temperature (T_b) in reptiles. There are some disadvantages, however, to this method. The animal must first be captured and handled, and the thermocouple must be inserted into the cloaca; such manipulations potentially raise the animal's breathing rate (Langkilde and Shine 2006) and, if prolonged, could initiate a stress response involving elevated plasma corticosterone (e.g., Moore et al. 1991). Furthermore, the animal's retreat to a different microenvironment when chased, and/or its subsequent handling, potentially result in an unrepresentative measurement of T_b. An experienced researcher is able to minimize these outcomes in most cases; however, alternative non-invasive methods are desirable.

Useful alternatives for long-term studies of T_b include radiotelemetry and intra-coelomically implanted temperature loggers. While these methods do not require frequent recapture of the animal, they still require the initial attachment of the device, which itself sometimes requires surgery (Charland 1995; Forsythe et al. 2004; Taylor et al. 2004). Consequently, these methods are not suitable for very small animals.

The advent of infrared technology potentially offers a non-invasive alternative for on-the-spot measurement of T_b in small reptiles. Both infrared imaging systems and hand-held thermometers are now available. Imaging systems have proved useful in controlled laboratory environments where relatively large systems can be set up for a long period of time, and if properly calibrated produce highly accurate results (Jones and Avery 1989). Unfortunately these systems are too bulky for use in the field. However, hand-held infrared thermometers (IRT) are available, at much lower cost. These devices consist of a handle, a sensor, and a laser sight. The sensor beneath the laser sight measures infrared radiation of the surface at which the IRT is aimed, and produces a temperature reading precise to about 0.1°C (see Methods), comparable to many thermocouples. Studies using IRT are currently being evaluated for medical purposes, and show promising results for use in some non-critical applications, although some reservations have been expressed (Banitalebi and Bangstad 2002; Hoffman et al. 1999; Leon et al. 2005).

An IRT potentially offers several advantages for measuring T_b in small reptiles. The method has already been used to study temperatures selected by small geckos on a thermal gradient (Christian et al. 1998; Werner et al. 2005) but no rigorous comparison of

results with those from a cloacal TC is available. The main aim of the present study was to determine if skin temperature (T_{sk}) measured with an IRT was sufficiently accurate to substitute for the standard method (cloacal TC) for inferring T_b in small lepidosaurian reptiles. Measurements of T_{sk} and T_b were collected both in the field and laboratory from adults of McCann's Skink (*Oligosoma maccanni*), and in the laboratory from juvenile Tuatara (*Sphenodon punctatus*). The usefulness of substrate temperature (T_{sub}, measured with an IRT) as a substitute for T_b on a thermal gradient was also examined for Tuatara.

Methods.—Adult McCann's Skinks of both sexes, including pregnant females (mean mass 3.53 ± 0.11 g), were captured from rock outcrops at Cloverdowns Farm, near Macraes Flat, New Zealand (45°28'S, 170°28'E, 600–700 m elev.). Captures of this diurnal, heliothermic species were made by day during the austral spring (8–14 October 2004). Although a few skinks were captured from basking positions on rocks, cool and windy weather meant that most skinks were under rocks.

Preliminary tests showed that hand capture was necessary to determine T_{sk} because skinks would otherwise escape before the IRT could be brought close enough (ca. 100 mm) for a reading. Upon capture, the field T_{sk} of 36 individuals was immediately taken by an IRT (Raytek, Raynger® model ST80 ProPlus™, Santa Cruz, California), which provides a reading precise to 0.1°C. Accuracy as reported by the manufacturer is ± 2°C between -18 and 23°C and ± 1°C above 23°C for surfaces with an emissivity of 0.95; we verified this by comparison with a thermocouple (see below for model) for surfaces including terracotta tile and paper. We assumed that the skin of the reptiles we studied had a similar emissivity, which appears reasonable as most biological materials have an emissivity in the medium to long infrared of between 0.90 and 0.99 (Willmer et al. 2000). Taking care to ensure that the laser beam avoided the eyes of animals and researchers, the IRT was pointed at the dorsal surface of the skink such that the target laser sights all fell on the posterior abdomen or pelvic region. Adult skinks typical of those studied had a mean width (± SE) at the posterior abdomen of 6.68 ± 0.12 mm (measured later in laboratory, N = 40). During measurement, skinks were held by their pectoral girdle over the surrounding substrate to avoid the handler's body heat from influencing the readings.

Immediately following measurement of T_{sk}, which usually took only a few seconds, a cloacal thermocouple (Digi-Sense® model 8528-40, Cole-Parmer, Niles, Illinois, USA; hereafter, "TC"), which had been calibrated to within 1.0°C against a reference thermometer (SAMA-CT40, Eveready Thermometer Co., West Patterson, New Jersey, USA), was used to measure cloacal T_b. Ambient temperature (T_a) was then measured with the TC at 1 m height in the shade.

Field T_{sk} measured with the IRT was compared with T_b measured with the TC using linear regression analyses and paired *t*-tests. The absolute magnitude of the difference between T_b and T_{sk} was plotted against T_a, and a regression was used to determine whether T_a affected the difference. At the time of measurement, we noticed five readings of T_{sk} to be very different from T_b. We re-measured T_{sk} of these skinks over a different substrate (rock versus grass). The second IRT measurement for these five skinks was always more similar to the TC reading than the first one, and this value was used for analyses (as we show later, the discrepancy was likely due to the way the IRT was oriented relative to the lizard's body rather than to the nature of the substrate per se).

Nine adult *O. maccanni* (pregnant females, mean mass 3.91 ± 0.17 g) were brought to the laboratory and placed on a thermal gradient lined with clean brown paper over a metal base-plate. Individual runways (8.5 × 100 cm) offered a temperature range from 16°C at one end to 34°C at the other end (see Rock et al. 2000 for further details of gradient). After a familiarization period of 14 hours, T_{sk} and T_b were measured up to three times over the following 12 h (1000, 1500 and 2200 h). Measurements of T_{sk} were in most cases obtained without handling, although in a few cases the skinks ran along the gradient and had to be restrained before measurements of either T_{sk} or T_b were taken. Measurements at night (2200 h) were made with the aid of a dim red light. The inclusion of night measurements increased the range of skin/body temperatures selected by the skinks. In total, 19 paired measurements were obtained from 9 skinks, and for the purposes of the comparison between methods these were treated as independent measures (analysis of time-of-day effects on mean T_b will be reported elsewhere). Differences between T_{sk} and T_b were examined using regression analysis and paired *t*-tests.

Ten juvenile *S. punctatus* of approximately 7 months age (mean mass 4.18 ± 0.37 g) were also placed on the thermal gradient. These tuatara had been obtained from eggs laid and incubated in captivity and were maintained indoors under semi-natural conditions of temperature and photoperiod. Data for T_{sk} and T_b were collected and analyzed as for skinks, except that the familiarisation period lasted 8 h and measurements were subsequently collected at five time points (0600, 1000, 1400, 1800 and 2200 h, with 0600 and 2200 h being in darkness). Substrate temperatures available within the gradient ranged from a mean of 13.6°C at the cool end to 33.1°C at the warm end. In addition to measurements of T_{sk} and T_b, at each time point the substrate temperature (T_{sub}) selected by each tuatara was measured by IRT directly alongside a hind limb of the tuatara. In total, 50 paired measurements of T_{sk} and T_b were obtained from ten tuatara, and analyzed as for skinks. The relationship between T_{sub} and T_b was also examined.

Results from the above experiments led us to suspect that background (substrate) temperature had an influence on T_{sk} when the IRT was held at close distance and with a certain orientation (at 90° to the animal's body axis). With such an orientation, the laser sight does not provide an accurate indication of the spot at which infrared radiation is being measured (owing to the offset between laser source and sensor). The manufacturer's instruction booklet alludes to this possibility under a section entitled "Reminders," in which it is recommended that, at distances less than 0.5 m, a manual sight on top of the IRT should be used instead of the laser.

We therefore tested the effect of using either the laser or manual sight for determining T_{sk} (and hence inferring T_b) in skinks. We also tested, using the laser sight, the influence of orientation of the IRT (relative to the skink's body axis) on T_{sk}. For this trial, 20 skinks with a body temperature of about 18°C were placed on a warm ceramic tile with a surface temperature of about 30°C. The first measurement of T_{sk} was made using the laser sight and with the IRT oriented at 90° to the body axis. The second measurement of T_{sk} was made with the IRT in the same position but using the manual sight. The third measurement of T_{sk} was made using the laser sight but with the IRT oriented in-line with the skink's body

axis. Finally, T_b was measured with the cloacal TC. All measurements for each skink were completed within about 30 seconds. Paired *t*-tests were used to compare each T_{sk} measurement with T_b.

Results.—By day, wild skinks had cloacal temperatures (T_b, measured with the TC) of between 10.4 and 28.6°C. Skin temperature (T_{sk}, measured with the IRT) showed a significant relationship with T_b ($r^2 = 0.586$, $df = 1, 34$, $P < 0.001$, Fig. 1A). Mean values differed by 1.21 ± 0.62°C (T_{sk} = 20.53 ± 0.95°C, T_b = 21.75 ± 0.81°C) but this difference was not significant (paired $t = 1.996$, $df = 35$, $P = 0.057$). Individual differences ranged up to 12.9°C, even after re-testing over a different substrate. Ambient temperature played a significant, albeit small, role in explaining the absolute magnitude of the difference between T_{sk} and T_b (data not presented; $r^2 = 0.189$, $df = 1, 34$, $P = 0.008$); in other words, the discrepancy between T_{sk} and T_b was reduced at warmer temperatures.

Depending on time of day, skinks on the thermal gradient selected a T_b of between 17.6 and 31.9°C. The relationship between T_{sk} and T_b was highly significant ($r^2 = 0.899$, $df = 1, 17$, $P < 0.001$; Fig. 1B), and mean values for T_{sk} (29.03 ± 1.16°C) and T_b (28.37 ± 0.81°C) did not differ (paired $t = 0.17$, $df = 18$, $P = 0.173$). The maximum discrepancy between T_{sk} and T_b was 4.1°C.

Tuatara on the thermal gradient selected a T_b of between 12.8 and 28.1°C. The relationship between T_{sk} and T_b was highly significant ($r^2 = 0.936$, $df = 1, 48$, $P < 0.001$; Fig. 1C), and mean T_{sk} (21.22 ± 0.63°C) did not differ significantly from mean T_b (20.92 ± 0.57°C; $t = 1.787$, $df = 49$, $P = 0.08$). The maximum discrepancy between T_{sk} and T_b was 3.2°C. The relationship between substrate temperature (T_{sub}) and T_b of tuatara (Fig. 1D) was more variable than that between T_{sk} and T_b, though still highly significant ($r^2 = 0.847$, $df = 1, 48$, $P < 0.001$). Mean T_{sub} and mean T_b came close to differing significantly ($t = 1.979$, $df = 49$, $P = 0.053$), and individual differences ranged up to 5.4°C.

Measurements of T_{sk} made with the IRT oriented at 90° to the skink's body axis were highly influenced by background temperature, regardless of whether the laser sight or manual sight was used (Fig. 2). Mean values for T_{sk} measured in this way differed greatly from T_b measured by TC ($t \geq 17.592$, $df = 19$, $P < 0.001$). However, when T_{sk} was measured with the IRT oriented in line

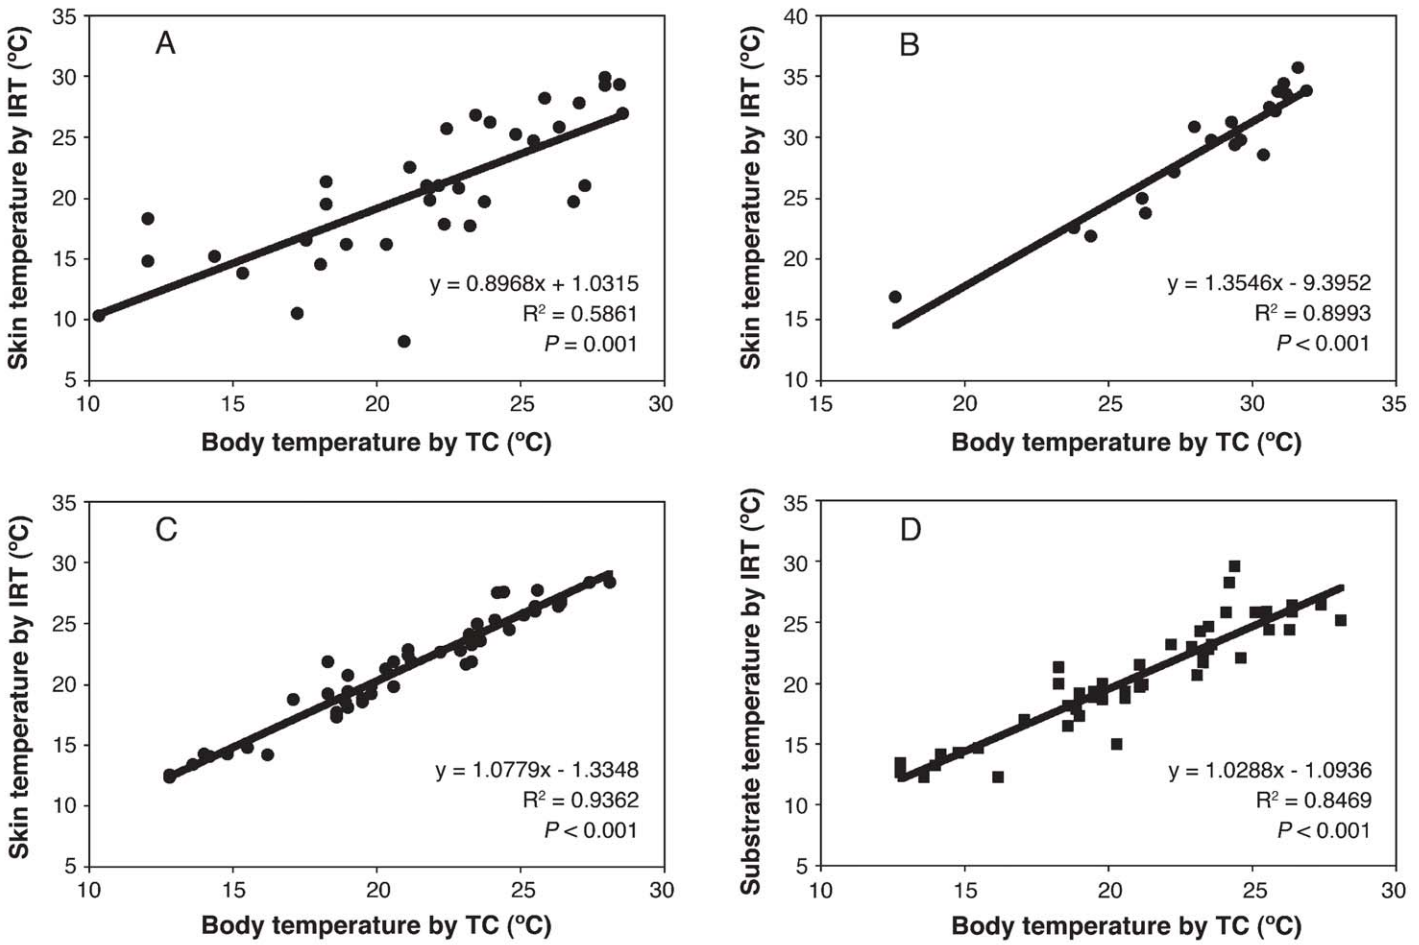

FIG. 1. Comparison of skin temperature (T_{sk}) or substrate temperature (T_{sub}), measured by infrared thermometer (IRT), with cloacal temperature measured by thermocouple (TC), in two small lepidosaurian reptiles. A) Skin temperature of adult McCann's Skinks (*Oligosoma maccanni*) in the field. B) Skin temperature of McCann's Skinks in the laboratory (free choice on thermal gradient). C) Skin temperature of juvenile Tuatara (*Sphenodon punctatus*) (free choice on a thermal gradient). D) Substrate temperature of juvenile Tuatara (free choice on a thermal gradient). Line equations and coefficients are for linear regression. In these data sets, the IRT was used without precise orientation relative to each animal's body axis.

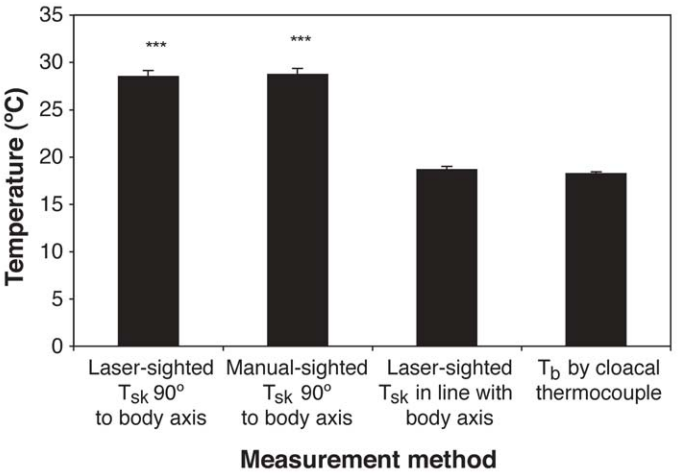

FIG. 2. Mean skin temperature (T_{sk}, measured by IRT) and body temperature (T_b, measured by TC) of the skink *Oligosoma maccanni* on a substrate of about 30°C. The first measurement of T_{sk} was made using the laser sight, with the IRT oriented at 90° to each skink's body axis. The second measurement of T_{sk} with the IRT was made with the same orientation but using the manual sight. The third measurement of T_{sk} was made with the laser sight and with the IRT oriented in line with each skink's body axis. Finally, T_b was measured (N = 20 for all measurements). Bars show standard error. *** indicates significantly different ($P < 0.001$) from T_b by TC.

with the skink's body axis, a much more accurate indication of T_b was obtained ($t = 2.012$, $df = 19$, $P = 0.059$). For the latter comparison, 95% of paired values differed by no more than 1.0°C (maximum difference 3.4°C).

Discussion.—In principle, the infrared thermometer (IRT) offers an attractive and non-invasive method for measuring T_b in small reptiles. In practice, we found its usefulness in the field with *O. maccanni* limited in that it needed to be brought to such a close distance that most animals had to be captured first, removing one advantage over the use of a thermocouple (TC). (In the thermal gradient, however, it was usually possible to measure T_{sk} without animal capture.) We also noted that in the field, although mean T_{sk} measured by IRT and mean T_b measured by TC did not differ significantly, the regression explained only 59% of the variation and there were several large discrepancies (up to 12.9°C) between T_{sk} and T_b. Many skinks had field body temperatures below 23°C, in a range where the accuracy of the IRT is reduced. Nevertheless, the discrepancies we observed were too great to be explained by this factor alone. Discrepancies could have also arisen from a real difference between skin and core body temperature, but we do not believe that thermal gradients of up to 12.9°C could exist over a few millimeters of body tissue in small skinks. This assumption is supported by research on the similar-sized *Lacerta vivipara* (3.5 g), in which core and skin temperatures differed by not more than 0.2°C (Jones and Avery 1989).

The most likely reason for occasional large discrepancies between T_{sk} and T_b in the field is that the IRT was not always precisely oriented in line with the skink's body axis. Thus, the background temperature is likely to have influenced some measurements. Further tests with *O. maccanni* in the laboratory showed that the influence of background temperature was substantial if the IRT was oriented at 90° to the skink's body axis, regardless of whether the laser or manual sight was used. However, with the IRT oriented in line with the skink's body axis, the effect of background temperature was eliminated, as the laser source and infrared sensor were now both in line with the skink's body.

Results for skinks and tuatara on the thermal gradient are consistent with the above interpretation. In these trials, the IRT may not have always been oriented in line with each animal's body axis, thus explaining occasional discrepancies between T_{sk} and mean T_b. However, the discrepancies were smaller than in the field for *O. maccanni*, probably because background temperature on the gradient was in most instances very similar to T_b. Overall, there was no significant difference between mean T_{sk} and mean T_b for either *O. maccanni* or *S. punctatus* on the thermal gradient, and the match between individual values is likely to be further improved with more care in orientation of the IRT.

Two previous studies have used T_{sk} measured with an IRT for inferring T_b selected by small lizards on a thermal gradient. In one study, T_{sk} was assumed to represent T_b of the gecko *Oedura marmorata* (mean species mass ~9–20 g) but no calibration was reported (Christian et al. 1998). In another, T_{sk} was calibrated against T_b for a combined sample of one or more individuals of the geckos *Goniurosaurus kuroiwae kuroiwae* (mean species mass 7.7 g) and *Eublepharis macularius* (mean species mass 47.1 g; Werner et al. 2005). A significant relationship was reported (regression $r = 0.83$; N = 21 measurements; $P < 0.0001$), although occasional discrepancies (magnitude not reported) were noted, especially in small individuals. Neither of these studies reported the orientation of the IRT relative to the lizards' bodies, so the possible influence of background temperature on the measurements is unknown.

Substrate temperature (T_{sub}) on a thermal gradient has sometimes been used as a surrogate for T_b in small reptiles, for example, for the semi-fossorial lizard *Chalcides ocellatus* on a substrate of sand (Daut and Andrews 1993). In our study with tuatara, although substrate temperature was easy to measure with little disturbance to the animal, it was not as precise an indicator of T_b as was T_{sk} measured with the IRT. Discrepancies presumably arise when animals occasionally move on the gradient to a region of cooler or warmer substrate than T_b. Given that further improvements in the accuracy of estimating T_b are probable with precise orientation of the IRT, we recommend measuring T_{sk} directly rather than T_{sub} when accurate estimates of T_b on a thermal gradient are required for small reptiles.

An IRT for measuring T_{sk} has considerable advantages over a cloacal TC for estimating T_b in small reptiles. Handling of animals is essentially eliminated when animals are confined (as on the thermal gradient), and thus the risk of a handling-induced increase in respiration rate (Langkilde and Shine 2006), as well as escape and other negative outcomes, is reduced. This could have benefits for both animals and researchers, making subsequent measures of animal temperature in a repeated-measures design (e.g., where time-of-day effects are of interest; Rock et al. 2000) less affected by previous disturbance. Werner et al. (2005) also pointed out a reduced risk of tail autotomy when using an IRT rather than a TC for measuring selected temperature in small geckos. Although we have not observed tail loss in either of our study species here (or the gecko *Hoplodactylus maculatus*: Rock et al.

2000) when measuring T_b by TC for animals on a thermal gradient, it is certainly true that handling and the risk of escape are reduced using the IRT.

Further studies are needed to assess the potential use of an IRT for inferring T_b in larger reptiles. Although some modeling suggests that reptiles under 30 g should act as though they have zero heat capacity (Bakken 1992), other work suggests that even in reptiles of this small size, lags between skin and core temperature could occur in animals that move into new thermal environments (Seebacher and Shine 2004). Differences between skin and core temperature will depend not only on animal size but also on the extent of temperature equilibration with the environment, and thus on the amount of movement by the animal and the extent to which the environment is thermally heterogeneous (Seebacher and Shine 2004). In a laboratory environment such as a thermal gradient where thermal equilibration is possible, or with sedentary wild animals in relatively homogeneous thermal environments such as adult tuatara emerged in forest, T_{sk} may yet provide a useful substitute for T_b. However, empirical studies are clearly needed before assuming the accuracy of an IRT for inferring T_b in reptiles larger than those studied here.

One area of biomedical interest where use of the IRT has been explored has been the measurement of body temperature in humans. Studies assessing the accuracy of IRT measurements of the inner ear in humans have found discrepancies of 2°C or more compared with the standard rectal temperature measured by a thermometer (Hoffman et al. 1999; Modell et al. 1998; Stavem et al. 1997). Similarly, in a comparison between IRT and TC methods for determining human skin temperature, differences between the two methods were often 1–2°C, precluding the use of IRT for studies where accurate measurements of T_b are necessary (Matsukawa et al. 2000). As in our initial trial with the IRT in the field for *O. maccanni*, a significant regression or correlation between the two measurements was not in itself a guarantee of accuracy (discussed further by Yaron et al. 1995).

In conclusion, the hand-held IRT is very easy, quick and convenient to use. If appropriately oriented when aiming at small reptiles, it records values for T_{sk} that can substitute for measurements of T_b taken with a cloacal TC, with the advantage for animal welfare that handling is reduced. If care is not taken with orientation and aiming, however, then discrepancies (potentially large) may arise due to the influence of background temperature. Our findings illustrate the importance of testing new equipment and methods against previously established methods, to ensure that the quality of data is acceptable for research purposes.

Acknowledgments.—Research was conducted under permits from the New Zealand Department of Conservation and approvals from the University of Otago Animal Ethics Committee. We acknowledge consultation with Ngati Koata regarding studies on tuatara and with Ngai Tahu regarding collection of McCann's Skinks. Our thanks to Lindsay Hazley and the Southland Museum and Art Gallery, Invercargill, for providing tuatara eggs from which juveniles were obtained, Keith and Margaret Philip for access to McCann's Skinks on their property, Karina Holmes and Jack Mace for field assistance, Marion Preest for assistance with equipment purchase, and Marion Preest, Anne Besson and two anonymous reviewers for comments on the MS. Research was supported by a University of Otago Research Grant to Alison Cree.

Comment on Papers by Hare et al. and Rowley and Alford

There is an uncertainty principle involved in measuring the body temperatures of small ectothermic animals: the mechanics of measuring are likely to affect the quantity measured. To take cloacal or core body temperatures, animals must be captured and handled, or logging or telemetry devices must be implanted or attached. Particularly for small animals with low thermal inertia, capture and handling may mean that body temperature changes before it is measured. Repeated capture and handling may disrupt normal behavior, so that accurate temperatures are measured, but are not relevant to normal behavioral patterns. Implantation or attachment of devices may lead to similar disruptions. Both papers demonstrate that, at least for frogs and small reptiles, the uncertainty can be reduced by measuring temperature using infrared thermometers (IRTs), which allow skin temperatures to be measured without handling. These temperatures are more likely to reflect the outcome of natural behavior, even when measured repeatedly, and to be unaffected by handling, so they should be more accurate estimates of the temperature of an undisturbed animal with normal behavior. This higher accuracy might be preferable to that of temperatures taken using other techniques, even if IRT temperatures were somewhat less precise. However, both papers demonstrate clearly that, if properly used, with an understanding of the parallax problems that arise when using IRTs to measure small areas at close distances, IRTs can provide both precise and highly accurate estimates of skin temperatures of frogs and reptiles. These mirror cloacal temperatures, at least in frogs and relatively small reptiles, and can thus be used as proxies for core body temperature. When it is important to avoid the effects of disturbance and handling, as when body temperatures are to be repeatedly taken during behavioral observations, this technique should prove to be an invaluable addition to the herpetologist's repertoire.

—Ross A. Alford and Jodi J. L. Rowley

Response to "Non-contact Infrared Thermometers Can Accurately Measure Amphibian Body Temperatures" by Jodi Rowley and Ross Alford

We agree with Rowley and Alford about the potential advantages of using an infrared thermometer (IRT) for measuring body temperatures in small amphibians and reptiles: reduced handling means potentially more reliable measurements, less stress to animals, and a reduced risk of disease transmission (especially relevant at present to amphibians)—and that IRTs can also allow more rapid data collection.

We also agree that the offset between the laser sight and infrared sensor raises the issue of parallax when IRTs are used with very small, narrow-bodied species that must be closely approached. This means, as we show, that care is needed when orienting the IRT to ensure that skin temperature, rather than temperature of the background, is what is being measured. This was presumably less of an issue with the larger and more compact frogs with which Rowley and Alford worked than with our small and elongate lepidosaurs.

Collectively, our studies seem broadly complementary, but largely or exclusively laboratory-based. We encourage more work by others to assess the significance of body size, body shape, and movements between different thermal environments on the potential lag between skin temperature (measured by an IRT) and core temperature, and on the practicality of using IRTs in the field with small species, which need to be closely approached.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 38, Number 1 (March 2007).

CAUDATA

AMBYSTOMA OPACUM (Marbled Salamander). **HABITAT**. Typically, adult *Ambystoma* utilize lentic habitats for breeding and egg deposition; such habitats include temporary and permanent ponds, flooded fields, and roadside ditches. However, previous reports indicate that up to six species of *Ambystoma* may utilize lotic habitats (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington. 587 pp.). Here we provide the first report of lotic habitat use by *Ambystoma opacum*.

On 25 Mar 2006 we encountered a stream pool containing *A. opacum* larvae in the Saline County State Fish and Wildlife Area (37°41'43"N, 88°23'19"W), Equality, Illinois, USA. The pool was ca. 180 cm in length, with a maximum depth of 45 cm and an average flow rate of 3 cm/sec. Initially, no larvae were visible in the pool, but disturbance of a submerged root system resulted in visible larval movement and subsequent identification. Five larvae were visible in the pool and three were collected for species verification. All larvae were between 15–17 mm total length, and none had developed rear legs. We also surveyed all stream pools within ca. 100 m upstream and downstream from the pool where the *A. opacum* larvae were collected, but no additional larvae were found.

To our knowledge, this is the first record of stream use by *A. opacum*. As all previous reports of lotic habitat use by *Ambystoma* concern species that deposit eggs directly into water, our observation is also the first record of lotic habitat use by a species of *Ambystoma* that typically deposits eggs in terrestrial nests (Petranka 1998, *op. cit.*). We thought it plausible that *A. opacum* larvae might have washed into the stream channel from upland ponds during a rain event; therefore, we searched the surrounding upland for > 300 m upstream and downstream from the pool for the presence of temporary ponds. No ponds or dry pond basins were found, and analyses of topographical maps support our observations. Whether adult female *A. opacum* deposited eggs directly into this pool, into terrestrial nests along the pool margin, or in the surrounding upland is unknown. The small sizes of pools in this stream suggest that during dry periods, these stream pools may be reduced to isolated pools similar in appearance to the temporary ponds typically utilized by *A. opacum*. In addition, we failed to encounter fish in this stream, suggesting that larval *A. opacum* could survive in these

pools until metamorphosis. Continued monitoring of this stream and surrounding streams in future years will help us determine if our observation represents a single occurrence or a common behavior.

Larvae were verified by Ronald A. Brandon. Specimens were deposited in the SIUC Fluid Vertebrate Collection (SIUC H-08675).

WILLEY** (e-mail bwill@siu.edu), Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA.

SIREN LACERTINA (Greater Siren). **DIET.** On 10 Sept 2006, a dead *S. lacertina* was retrieved from a minnow trap in Dry Bay, a 5-ha fishless Carolina bay located on the Dept. of Energy Savannah River Site, Aiken Co., South Carolina, USA. The siren was returned to the laboratory and frozen. On 28 Nov 2006, the siren was dissected and an *Ambystoma talpoideum* (Mole Salamander) was found in its stomach. The siren was 310 mm SVL, 485 mm TL, and mass was 236 g. Its mouth had a maximum vertical gape of ca. 10 mm with a horizontal opening of ca. 15 mm. The remains of the *A. talpoideum* weighed 3.27 g and appeared to be in the early stages of digestion (e.g., the skin was mostly digested, but the organs were relatively identifiable). The head was separated from the rest of the body and was possibly decapitated during mastication. Although *S. lacertina* are known to consume small fish (Hanlin 1978. Copeia 1978:358–360), this is the first report of a non-fish vertebrate consumed by *S. lacertina*.

Salamanders were captured under scientific research permit 56-2003 from the South Carolina Dept. Natural Resources. Funding was provided by the National Science Foundation (Awards DEB-0242874 and DBI-0139572) and the Savannah River Ecology Laboratory under Financial Assistance Award DE-FC09-96SR18-546 between the University of Georgia and the U.S. Dept. of Energy.

TARICHA GRANULOSA (Rough-skinned Newt). **PREDATION**. On 6 Aug 2006, JRT and SF observed an immature Great Blue Heron (*Ardea herodias*) catch and swallow an adult *Taricha granulosa* at a small pond at Point Reyes National Seashore, Marin County, California, USA (UTM 505530E, 4219240N). The heron was observed at Abbott's Lagoon pond at 1225 h on a clear, sunny day. The heron was seen catching the newt, holding the newt in its bill (Fig. 1), moving to a shallower part of the pond, and then repeatedly dunking the newt in the pond. The heron also dropped the newt a few times, only to pick it back up and proceed to dunk it in the water. After 5–8 minutes the heron tilted its head back and swallowed the newt whole. The heron was photographed >10 min after it ate the newt. This same behavior had been observed by SF on several occasions at the same pond during August. On 12 Aug, a Great Blue Heron was observed by SF eating three newts over a 45 min period. This suggests that the heron survived eating newts, and continued to include newts as part of its diet. We subsequently searched the perimeter of the pond and did not find any dead herons.

FIG. 1. Great Blue Heron (*Ardea herodias*) holding a *Taricha granulosa* in its bill. A single heron was observed eating as many as three newts in 45 min.

The newt can be identified to species from the photo, but we have also conducted 72 amphibian surveys at the pond since 1993. We found *T. granulosa* on 12 occasions and have never found *T. torosa*, the only other *Taricha* present in the area. Based on 1426 amphibian surveys conducted throughout the park since 1993 (309 sites), the nearest known *T. torosa* localities are 8.5 km and 12 km away.

Brodie et al. (1974. Copeia 1974:506–511) described the skin toxins of *T. granulosa* as more toxic than any known substances from the skin of other salamanders. The Common Gartersnake (*Thamnophis sirtalis*) is the only species reported to regularly feed on *T. granulosa*. Of the six species of North American newts, birds have been reported to eat only *T. granulosa* (Lannoo 2005. Amphibian Declines: The Conservation Status of United States Populations. Vol. 2. Univ. California Press, Berkeley, California, xxi + 1094 pp.), and in all cases, the birds had been found dead (Marks and Doyle 2005. *In* Lanoo [ed.], Amphibian Declines: The Conservation Status of United States Populations. Vol. 2, pp. 894–900. Univ. California Press, Berkeley, California). The birds included a Pied-Billed Grebe (*Podilymbus podiceps*), Mallard (*Anas platyrhynchos*), and domestic chicken (*Gallus domesticus*). Brodie (1968. Copeia 1968:307–313) placed the tail of a *T. granulosa* in the rear of the mouth of a Great Blue Heron and reported that the heron was unable to stand upright after 90 sec, and was dead after 120 sec. This suggests that Great Blue Herons have little tolerance for tetrodotoxin and that the apparent washing behavior reported above might be effective at reducing the level of toxin on the skin of the newts. However, Hanifin et al. (1999. J. Chem. Ecol. 25[9]:2161–2175) reported variation in *T. granulosa* toxicity, both within populations and between populations. *Taricha granulosa* at the Point Reyes pond almost certainly have low toxicity.

ANURA

ASCAPHUS TRUEI (Tailed Frog). **SPIDER PREY**. Few data describe the diet of the postmetamorphic *Ascaphus truei*. Springtails (Collembola), amphipods (Amphipoda), stonefly nymphs (Plecoptera), fly larvae (Diptera), and beetle larvae (Coleoptera) dominated the prey of 11 adult and 39 juvenile *A. truei* from Trinity County, California (Bury 1970. Copeia 1970:170–171). Bury (1970, *op. cit.*) also reported that six juvenile *A. truei* had each taken a spider (Araneae), but these were not identified to species, a condition necessary to properly interpret predator-prey natural history. Here, we report the first observation of spider prey identified to species for adult *A. truei*.

On 14 Aug 2006 at 1530 h, FTW found an adult male (36 mm SVL) *A. truei* along an unnamed headwater tributary of the South Fork Willapa River, Pacific County, Washington (46.5790N, 123.7239W, NAD 27, 224 m elev.). The stream is 2nd-order (*sensu* Strahler 1952. Geol. Soc. Am. Bull. 63:1117–1142), ca. 0.8 m wide, and located within a 55-year old second-growth mixed Western Hemlock (*Tsuga heterophylla*) and Douglas-fir (*Pseudotsuga menziesii*) managed forest on an intrusive basalt geology. The riparian canopy was undifferentiated from Western Hemlock/Douglas-fir vegetation upslope, but the riparian understory was differentiated by scattered Stink Currant (*Ribes bracteosum*), Salmonberry (*Rubus spectabilis*), Lady Fern (*Athyrium filix-femina*), and Fringecup (*Tellima grandiflora*). Skies were clear; air temperature was 18°C. The frog, captured <1 m from the stream, had an adult (ca. 13 mm cephalothorax–abdominal length) male Folding-door Spider, *Antrodiaetus pacificus*, in its mouth. FTW removed the spider from the frog, preserved it, and measured and released the frog at the capture site.

Antrodiaetus pacificus is a soil-dwelling spider in the Suborder Mygalomorphae, which also includes tarantulas (Coyle 1971. Bull. Mus. Comp. Zool. 141:269–402). Though relatively small for a mygalomorph, it is one of the larger spider species in Willapa Hills conifer forests. Females live in burrows, whereas mature males wander seasonally in search of mates. As the species is often recorded from riparian forest habitats in the Pacific Northwest (Parsons et al. 1991. Invertebrates of the H. J. Andrews Experimental Forest, Western Cascade Range, Oregon. V: An Annotated List of Insects and Other Arthropods. USDA Forest Service, GTR, PNW-GTR-290, Portland, Oregon; Johnston 1994. California Forests and Woodlands: A Natural History. Univ. California Press, Berkeley. 222 pp.; Hocking and Reimchen 2002. BMC Ecology 2:4), terrestrial stream-margin wandering of males may make them vulnerable to adult *A. truei*, which can be common in this habitat (Jones et al. 2006. Amphibians of the Pacific Northwest. Seattle Audubon Society, Seattle, Washington. 227 pp.). However, at any given site, availability of male *Antrodiaetus* as prey is likely limited to a few days each year, varying from early August to October for different coastal Washington populations of the spider (Coyle, *op. cit.*; RLC, unpubl. data). Many more common spiders are available as frog prey in this habitat, including some ground dwellers in the same size range as *Antrodiaetus* (e.g., *Cybaeus* spp. [family Cybaeidae], which are abundant much of the year in coastal conifer forests).

The *A. pacificus* was deposited in the Arachnology collection at the University of Washington Burke Museum. This is contribution No. 13 of the Forests and Fish Section of the Washington Department of Fish and Wildlife's Habitat Program Science Division.

BUFO AMERICANUS (American Toad). **HINDLIMB DEFORMITIES.** Amphibian ecologists and the public have recently given a great deal of attention to the issue of amphibian limb deformities. It has become evident there are many causes of amphibian deformities (e.g., Blaustein and Johnson 2003. Front. Ecol. Environ. 1:87–94; Sessions 2003. *In* Semlitsch [ed.], Amphibian Conservation, pp. 168–186. Smithsonian Press, Washington, D.C.). To better understand the extent and effects of amphibian limb deformities, additional information is needed on the rates of amphibian limb deformities from a variety of locations and species, particularly from ponds that appear relatively undisturbed or contaminated, to provide a better baseline for comparison to mass deformity events.

While collecting information on the performance of metamorphs from three local ponds, we examined several hundred American Toad tadpoles for limb deformities. The three ponds (Spring Peeper, Olde Minnow, and Taylor-Ochs) examined were on the Denison University Biological Reserve (Granville, Licking County, Ohio, USA) and are apparently free from any major pollutants or disturbance (see Schultz and Mick 1998. Ohio Biol. Surv. Notes 1:31–38 for a description of the ponds). We collected American Toad metamorphs from the water's edge of each pond from 2–9 June 2006. Each metamorph was examined for deformities and the type of deformity, if present, was recorded. We found hind limb deformities of varying degrees in two of the three ponds (Table 1). The observed frequencies of hind limb deformities in the three ponds ranged from 0–3.6%. These values fall within the range of frequencies observed in other species for historical records (i.e., prior

TABLE 1. Incidence of hindlimb deformities in American Toad, *Bufo americanus*, metamorphs from three ponds in central Ohio. All deformities were ectromelia of the femur or the tibiafibula (*sensu* Meteyer 2000. Field Guide to Malformations of Frogs and Toads with Radiographic Interpretations. USGS Biol. Sci. Rep. USGS/BRD/BSR-2000-0005).

	N Examined	N Deformed	% Deformed
Spring Peeper Pond	172	1	0.6%
Olde Minnow Pond	215	8	3.6%
Taylor-Ochs Pond	155	0	0%

to 1980) or for relatively undisturbed sites (e.g., Ouellet et al. 1997. J. Wildl. Dis. 33:95–104; McCallum and Trauth 2003. J. Wildl. Dis. 39: 522–528; Eaton et al. 2004. J. Herpetol. 38:283–287). The two ponds (Spring Peeper and Olde Minnow) where we found deformities were also the ponds with the slowest tadpole growth rates, smallest metamorphs, and highest numbers of predators (mosquitofish and dragonfly nymphs) (G. R. Smith et al., unpubl. data).

Submitted by **GEOFFREY R. SMITH, CHRISTOPHER J. DIBBLE, ALLISON BOYD, MEGAN E. OGLE**, **ANDREW J. TERLECKY,** and **CHRISTOPHER B. DAYER**, Department of Biology, Denison University, Granville, Ohio 43023, USA (e-mail: smithg@denison.edu).

BUFO TERRESTRIS (Southern Toad). **ARBOREAL BEHAVIOR**. North American *Bufo* are highly terrestrial ground-dwellers. Only a few accounts describe climbing behavior: a *Bufo americanus* climbing a steep rocky incline in Tennessee, USA (G. Lepera, pers. comm.), *B. marinus* found in natural tree holes in Venezuela (Mijares-Urrutia et al. 1996. Herpetol. Rev. 27:138), and *B. valliceps* in arboreal refugia in Texas, USA (Neill and Grubb 1971. Copeia 1971:347–348). Here, I report an observation of a *B. terrestris* using an arboreal tree cavity as a refuge on Cumberland Island, Camden County, Georgia, USA.

At 2230 h on 23 Sept 2006, I found a funnel-shaped cavity (ca.10 cm wide by 15 cm deep) at a height of ca. 1.6 m on a mature oak (*Quercus* sp.). The cavity likely originated from a branch that broke at its base, with subsequent decomposition of the heartwood. Inside the hollow, I found an adult *Bufo terrestris* resting about 10 cm from the entrance. The toad retreated inside the hollow, which slightly curved towards the trunk of the tree and stopped at what coincided with the middle of the branch. I probed the hollow with a piece of grass in an attempt to determine whether it continued past the curve, but I was unsuccessful in finding an opening. The toad inflated its body, raised its back, and pointed its paratoid glands at me, but did not retreat further.

I was unable to discern how the toad reached the cavity. Because of the relative remoteness of the locality, it is unlikely that humans put it there. Either the toad climbed up the outside of the vertical trunk until it reached the hollow's opening, or it used a vertical open space within the tree's trunk and followed it until it reached the cavity. However, no external opening to such an internal cavity was found at the base of the tree.

I thank C. Kenneth Dodd, Jr. for helpful comments on the manuscript.

BUFO WOODHOUSII (Woodhouse's Toad). **CANNIBALISM.** Little information exists on the feeding habits of *Bufo woodhousii* although they are presumed to feed on a variety of invertebrates (Lannoo 2005. Amphibian Declines. The Conservation Status of United States Species. Univ. California Press, Berkeley. 1094 pp.). In Kansas, *B. woodhousii* has been reported to feed on bees, beetles, insect larvae, spiders, and ants (Smith 1934. Amer. Midl. Nat. 15:377–528). Smith and Bragg (1949. Ecology 30:333–349) examined the stomach contents of 517 adult and 43 juvenile *B. woodhousii* from Oklahoma and reported no vertebrate remains. However, Smith and Bragg (*op. cit*.) reported the consumption of a small lizard by a juvenile *B. woodhousii* maintained in captivity. In Nebraska, *B. woodhousii* is reported to feed on beetles, ants, spiders, and other invertebrates (Hudson 1942. Nebraska Cons. Bull. 24:1–146).

During summer 2006, 56 *B. woodhousii* were collected at Beckius Pond (41.12529°N, 101.37276°W) Keith Co., Nebraska. Twenty-eight toads were collected during the night (2230–2330 h) on 23 July 2006 and 28 toads were taken during the day (1430–1530 h) on 27 July 2006. Toads were placed in refrigeration until dissection. Toads were euthanized and SVL and gape size were recorded to the nearest mm for each individual. The stomach, small intestine, and large intestine were removed, and the stomach was separated from the rest of the gastrointestinal tract. Each stomach was opened and preserved in 70% ethanol. The stomach contents were examined under a dissecting microscope, and identified into several broad categories and recorded as frequencies of organism ingested. Arthropods were identified to order according to Triplehorn and Johnson (2005. Borror and Delong's Introduction to the Study of Insects. 7th ed. Thomson, Grooks/Cole. 864 pp.).

Toads ranged from 2.9–7.3 cm SVL (mean 4.5 ± 1.2 cm) and gape size 8–28 mm (mean 1.67 ± 0.47 cm). Toads fed on 11 different groups of arthropods; 1944 items were recovered from stomach contents, including Diptera (1440), ants and other Hymenoptera (378), Coleoptera (93), Orthoptera (10), Hemiptera (8), Odonata (6), Pseudoscorpiones (3), Araneae (2), Lepidoptera (2), Homoptera (1), and Isopoda (1). Additionally, three toads contained remains of four smaller *B. woodhousii*. A single male collected at night (SVL 6.7 cm) contained one partially digested *B. woodhousii* (ca. 2.5 cm), and two toads (one female SVL 6.1 cm; one male SVL 6.6 cm) collected during the day contained one and two partially digested *B. woodhousii* (ca. 2.0–2.5 cm), respectively.

Although there are reports of ranids feeding on bufonids (Pearl and Hayes 2002. Am. Midl. Nat. 147:145–152) and ranid cannibalism (Stuart and Painter 1993. Herpetol. Rev. 24:103) we are not aware of any reports of bufonid cannibalism. These are important observations as many bufonids are considered ant and beetle specialists (Clarke 1974. Am. Midl. Nat. 91:140–147; Smith and Bragg, *op. cit.*).

We thank K. J. Hubbard, T. M. Humphrey, J. A. McNair, B. G. Powers, and M. R. Waltke for help in collecting toads, Cedar Point Biological Station, Univ. Nebraska-Lincoln for providing facilities, and M. Bolek for comments on the manuscript.

CHAUNUS ARENARUM (Argentine Toad). **ENDOPARASITES.** *Chaunus arenarum* ranges from northern Jujuy Province to the southern borders of Neuquén Province reaching 2400 m in La Rioja Province, Argentina. The species also occurs in southern Brazil, Uruguay, and Bolivia (Cochabamba) (Cei 1980. Amphib-

ians of Argentina. Monit. Zool., Italia, Firenze, Monogr. 2:1–609). Previous reports of nematodes in *C. arenarum* are in Baker (1987. Mem. Univ. Newfoundland, Occas. Pap. Biol. 11:1–325). The purpose of this note is to report the nematodes *Oswaldocruzia proencai* and *Ophidascaris* sp. in *Chanus arenarum* from Argentina.

Three *C. arenarum* (one male SVL 80 mm and one female 110 mm SVL) from Itaú River (22°20'51"S, 64°05'47.7"W; 483 m elev.), and one male (SVL = 83 mm) from Astilleros (22°23'01"S; 64°06'14.4"W; 493 m), General San Martín Department, Province of Salta, Argentina were collected in Sept 2005. They were deposited in the Herpetology Collection, Fundación Miguel Lillo as 17186–17187, and 17196. The body cavity was opened by a mid-ventral incision and the digestive tract was removed. The esophagus, stomach, and small and large intestines were longitudinally slit and the contents were examined for helminths using a dissecting microscope. Two species of Nematoda were found: *Oswaldocruzia proencai* (1 male, 3 females) in the large intestines and *Ophidascaris* sp. (2 juveniles) in the stomach. They were deposited in the Helminthological Collection, Fundación Miguel Lillo as *O. proencai* (CH 07443; CH 07448) and *Ophidascaris* sp. (CH 07445).

Slimane and Durette-Desset (1995. Revue Suisse Zool. 102:635–653) redescribed *Oswaldocruzia mazzai* as a parasite of *C. marinus* from Argentina, and in so doing reassigned specimens from *C. schneideri* (as *Bufo paracnemis), Leptodactylus ocellatus*, and *L. bufonius* collected in Paraguay by Lent et al. (1946. Mem. Inst. Oswaldo Cruz 44:195–214) to a new species, *Oswaldocruzia proencai. Oswaldocruzia proencai* differs from *O. mazzai* in morphology of the cephalic vesicle, that of *O. mazzai* is simple, that of *O. proencai* is in two parts. Hendrikx (1983. Zeits. fur Parasiten. 69:119–126) reported oral infection of toads by *Oswaldocruzia* sp.

Ophidascaris sp. is a member of the Ascaridae, which typically utilizes vertebrates as intermediate hosts in which development to the stage infective to the definitive (final) host occurs (Anderson 2000. Nematode Parasites of Vertebrates. Their Development and Transmission. CABI publishing, Wallingford, Oxon, U.K. 650 pp.). *Oswaldocruzia proencai* and *Ophidascaris* in *C. arenarum* are new host records.

CHAUNUS MARINUS (Cane Toad). **PREDATION**. *Chaunus marinus* is native to South and Central America and produces cardiac poisons known as bufotoxins in their paratoid glands and skin. In northeastern Australia, Hawaii, the Philippines, South Florida, and the Caribbean, where the species has been introduced, the Cane Toad is noxious or lethal to many vertebrate predators, including quolls (*Dasyurus* spp.), monitor lizards (*Varanus* spp.), snakes, and domestic dogs (Lever 2001. The Cane Toad: The History and Ecology of a Successful Colonist. Westbury, Otley, UK, 230 pp.; Phillips et al. 2003. Conserv. Biol. 17:1738–1747). After a predator bites or mouths a toad, death or temporary paralysis occurs within minutes, with foaming at the mouth, vomiting, and convulsions often being observed (Covacevich and Archer 1975. Mem. Queensland Mus. 17:305–310; Lever 2001, *op. cit*.; Phillips et al. 2003, *op. cit*.).

On a late afternoon in mid-November 2001, we observed an adult Common Opossum (*Didelphis marsupialis*) climb a 5-m tall avocado tree outside our kitchen window in Gamboa (9°07'N, 79°38'W), a small township that borders the Panama Canal and Soberania National Park in central Panama. It was holding in its mouth a large and apparently recently killed Cane Toad, with an estimated SVL 12–13 cm. To our surprise the opossum completely consumed the toad, initially gnawing and swallowing its rostrum and head, and then proceeding to its hindquarters and rear legs, over a period of several minutes. The opossum was 6 m away from us and we watched it closely with 10-power binoculars. The large paratoid glands of the Cane Toad were readily visible, and we anticipated that the opossum would attempt to avoid these, but it consumed the entire toad with apparent impunity.

After the toad was entirely eaten, the opossum remained in the tree and under our observation for about 20 min until darkness approached. As it rested in the tree it thoroughly licked clean its bloody paws and face and showed no signs of poisoning or distress. We do not know the ultimate fate of the opossum, but there was no dead body anywhere in the vicinity the following morning. The Cane Toad is common in the mosaic of lawns and secondary forest in Gamboa, and the combination of its large body size, distinctive head shape, massive paratoid glands, mottled yellow-brown dorsal coloration, and warty skin surface easily discriminate it from other toad species in the area (e.g., *Rhaebo haematiticus, Rhinella alatus* (*typhonius*); Ibañez et al.1999. The Amphibians of Barro Colorado Nature Monument, Soberania National Park, and Adjacent Areas. D'Vinni Editorial Ltd., Bogota, Colombia. 187 pp.). Aside from the resilience of the opossum to Cane Toad poisoning, we were surprised to see the event occurring before nightfall, as both the opossum and Cane Toad are typically nocturnal (Emmons and Feer 1997. Neotropical Rainforest Mammals: A Field Guide. Univ. Chicago Press, Chicago. 307 pp.; Ibañez et al. 1999, *op. cit*.).

We described our observation to various herpetologists including the late Stanley Rand (a Smithsonian Institution herpetologist and long-term resident of Gamboa). None had observed or heard of similar accounts. There are several possible explanations for our observation. It is possible that bufotoxins are toxic to opossums but are manifested only slowly, or that the toad we observed was somehow deficient in toxin production. Alternately, the Common Opossum, whose geographic range in Central and northern South America overlaps broadly with the natural range of the Cane Toad, might have evolved specific resistance to bufotoxins. Perhaps the most plausible explanation, however, is that Common Opossums might be broadly immune or resistant to a wide range of organic toxins. This latter interpretation is supported by the observation that *Didelphis* opossums are immune to the venom of crotalid vipers, on which they are known to prey (R. S. Voss, American Museum Natural History, pers. comm.), and that this immunity is conferred by a so-called Lethal Toxin Neutralizing Factor, originally isolated from *D. virgianus*, which neutralizes a

wide range of snake, scorpion, and bee venoms as well as many animal, plant, and bacterial toxins (Lipps 1999. J. Venom. Anim. Toxins 5:56–66). The remarkable physiological tolerance of opossums is in striking contrast to most predatory vertebrates in areas where Cane Toads have been introduced, especially in Australia where no native toads occur, for which the Cane Toad is highly toxic.

Our thanks to A. Crawford, R. Kays, J-M. Hero, S. Rand, and R. Voss for discussion or comments on the manuscript.

CHAUNUS POMBALI (Pombali's Toad) **PREDATION.** *Chaunus pombali* is found extensively in Minas Gerais State, southeastern Brazil, where this species occurs in the Atlantic rainforest and transition areas with the Cerrado formation (Baldissera et al. 2004. Arq. Mus. Nac., Rio de Janeiro 62:255–282).

During an anuran survey on 30 Aug 2006 in Viçosa, Minas Gerais State (20°45'S, 42°51'W), we observed predation of *C. pombali* by the exotic American Bullfrog (*Rana catesbeiana*). The observation occurred at a permanent dam on the Universidade Federal de Viçosa campus. At 1840 h, we observed an adult male *R. catesbeiana* holding an individual *C. pombali*, with the head and forelimbs protruding out of the mouth. For ca. 5 min. the *R. catesbeiana* remained motionless, then jumped into the water still holding the *C. pombali*. Stomach content analysis of a *R. catesbeiana* collected on 28 Sept 2005 (SUL 147.95 mm, Museu de Zoologia João Moojen de Oliveira, Universidade Federal de Viçosa, MZUFV 6374) from the same locality revealed a whole *C. pombali* (SVL 56.1 mm), indicating that predation on this species is not uncommon.

Rana catesbeiana was introduced into Brazil in the 1930s for commercial breeding. Poor management practices and high survival of individuals in wild habitats have allowed this species to establish viable populations in many regions of the country. Amphibians represent a substantial part of the diet of *R. catesbeiana* (Pearl et al. 2004. Copeia 2004:11–20). Our observations suggest that the poison glands of *C. pombali* do not deter predation by *R. catesbeiana*.

We thank Jorge A. Dergam for his comments on this note. ETS thanks CNPq for financial support.

COPHIXALUS ORNATUS (Ornate Nursery Frog). **CHYTRIDIOMYCOSIS.** Chytridiomycosis is an emerging infectious disease linked to amphibian population declines worldwide (Berger et al. 1998. Proc. Natl. Acad. Sci. 95:9031–9036). The chytrid fungus *Batrachochytrium dendrobatidis*, causative agent of chytridiomycosis, has an incredibly broad host range: it is currently known to infect over 160 amphibian species in two orders and 14 families (Speare and Berger 2004. www.jcu.edu.au/school/phtm/PHTM/frogs/chyglob.htm, updated with recently published accounts). Only seven of these species, however, are direct developers that bypass the free-swimming tadpole stage (*Eleutherodactylus cruentus, E. emcelae, E. melanostictus, E. karlschmidti, E. saltator, E. coqui*, and *Leiopelma archeyi*). Tadpoles are thought to be an important life stage with respect to disease transmission; they stand a high chance of being exposed to the fungus' aquatic zoospores and they do not succumb to chytrid infections, making them likely disease reservoirs (Daszak et al. 1999. Emerg. Inf. Dis. 5:735–748). Currently, there are no records of chytridiomycosis in Australian direct-developing frog species.

On 23 Sept 2005, KMK captured a male *Cophixalus ornatus* that was calling while perched on a leaf 2 m from the edge of Babinda Creek (70 m elev.), in Queensland, Australia. KMK firmly ran a cotton swab over the frog's dorsum, ventrum, sides, thighs, and the webbing of its feet, and used quantitative PCR (Boyle et al. 1994. Dis. Aquat. Org. 60:141–148) to test for the presence of *Batrachochytrium dendrobatidis*. Thirty-one chytrid zoospores were detected on the swab. This represents the first record of chytridiomycosis in an Australian direct-developing frog species, and only the eighth record worldwide.

There are no published reports of population declines in *C. ornatus*, a species whose large geographic range encompasses the localities of many of north Queensland's recent amphibian declines and disappearances, including that of *Taudactylus acutirostris* (the last known individual of which died of chytridiomycosis in 1995; Wright et al. 2001. J. Herpetol. Med. Surg. 11:14–27). Our finding of chytridiomycosis in *C. ornatus* supports the hypothesis that while all frog species may be exposed to the disease, there are ecological differences among sympatric species that might lead to differing disease outcomes, ranging from no effect on the population to mass mortality events and local extinctions (Daszak et al. 1999, *op. cit.*; Hero et al. 2005. J. Zool. Lond. 267:221–232).

Submitted by **KERRY M. KRIGER** (e-mail: kerry@savethefrogs.com), and **JEAN-MARC HERO** (e-mail: m.hero@griffith.edu.au), Centre for Innovative Conservation Strategies, Griffith University, PMB 50 Gold Coast Mail Centre, Queensland, 9726, Australia.

DENDROBATES AURATUS (Green and Black Poison Dart Frog). **LARVAL PREDATION.** *Dendrobates auratus* was intentionally introduced onto the island of O'ahu, Hawai'i in 1932 from Taboga Island, Panama for mosquito control. *Phelsuma laticauda* was accidentally introduced from Madagascar in 1996 to the University of Hawaii at Manoa. Both species are well established in the Manoa Valley.

While observing *D. auratus* tadpole depositions in the axils of a large *Vriesea imperialis* (Bromeliaceae), we often noticed adult *P. laticauda* on the leaves. At 0835 h on 1 Aug 2005, we witnessed an adult *P. laticauda* staring at the water in an upper axil of a large (ca. 1 m diameter at the base) *V. imperialis*. The skies were clear and the temperature was 26.2°C. The *P. laticauda* did not appear to notice our observations and continued to stare at the surface of the water. It moved lower into the axil until its snout was ca. 0.5 cm from the surface and continued to stare at the surface. It did

this for ca. 3 minutes. At this point, a *D. auratus* tadpole ca. 2 weeks old (2.5 cm total length) swam to the surface. Almost instantly, the *P. laticauda* struck at the tadpole and pulled it out of the water headfirst. It shook the tadpole back and forth three of four times and cocked its head back and swallowed all but the tip of the tail. It then quickly walked up the leaf and finished swallowing the tadpole. We observed the gecko for ca. 30 min after the predation event before it disappeared into the leaf litter at the base of the bromeliad.

A second predation event occurred at 1200 h on 28 Aug 2005 that was practically identical to the previous event. A different adult *P. laticauda* consumed a *D. auratus* tadpole of comparable size in a different *V. imperialis* ca. 0.4 km away. To our knowledge, this behavior has not been observed in the field. This is probably due to the fact that the natural distribution of these two species does not overlap.

We thank the Harold B. Lyon Arboretum, specifically Ray Baker, the Hawaii Department of Land and Natural Resources, specifically Norma Bustos, Jimmy Clark, and Warren Wong, for assistance and access to private property.

DISCOGLOSSUS GALGANOI (West Iberian Painted Frog). **PREDATION.** *Discoglossus galganoi* is endemic to the western half of the Iberian Peninsula (Spain and Portugal). Much information exists about predators of adults and juveniles (review in Martínez-Solano 2003. Sapillo pintojo ibérico - *Discoglossus galganoi*. Enciclopedia virtual de los vertebrados españoles. Museo Nacional de Ciencias Naturales, Madrid. www.vertebradosibericos.org; García-París et al. 2004. Fauna Ibérica. 24. Amphibia, Lissamphibia. Museo Nacional de Ciencias Naturales, CSIC, Madrid. 640 pp.), although relatively little is known about predators of the larvae. Aquatic insects, fish, water snakes (*Natrix maura*, *N. natrix*), and amphibians (*Triturus marmoratus*) have been cited as predators of the larvae (García-París 1985. Los Anfibios de España. Publicaciones de Extensión Agraria, Madrid. 287 pp.; Barbadillo 1987. La Guía de Incafo de los Anfibios y Reptiles de la Península Ibérica, Islas Baleares y Canarias. Ed. Incafo, Madrid. 694 pp.; Salvador and García-París 2001. Anfibios Españoles. Canseco Ed., Talavera de la Reina. 269 pp.).

Discoglossus galganoi reproduces in shallow seasonal ponds, thus larvae may suffer high mortality when these ponds dry. It tolerates moderate concentrations of salt in breeding pools, therefore it can breed in marine cliff rainwater pools very close to the sea (Curt and Galán 1982. Esos Anfibios y Reptiles Gallegos. Ed. J. Curt, Pontevedra. 166 pp.; Galán 2003. Anfibios y Reptiles del Parque Nacional de las Islas Atlánticas de Galicia. Faunística, Biología y Conservación. Organismo Autónomo Parques Nacionales, Ministerio de Medio Ambiente, Madrid. 276 pp.). Reproduction in Galicia (northwest Spain) lasts from December until July (Galán and Fernández 1993. Anfibios e Réptiles de Galicia. Ed. Xerais, Vigo. 501 pp.; Vences 1994. Salamandra 30:81–83).

In some marine cliffs near the Hércules Lighthouse in the city of A Coruña (Galicia, northwest Spain; UTM 29T NJ 48 03; 43°23'N, 8°24'W), a population of *D. galganoi* reproduces in a series of small (average 250 × 100 cm; 7 cm average depth, range 1–35 cm) seasonal rainwater pools and run-offs, situated in the cracks and hollows of the cliff rock. These pools are located in the upper region of the marine cliffs, 9–15 m from the sea (depending on the tides). During the frequent storms, they receive spray from the surf, thus during these periods the water salinity is relatively high. The only amphibian that reproduces in these pools is *D. galganoi*. These seasonal pools have practically no larval predators. In this area, *D. galganoi* reproduces from November to June, with larvae present from the end of December until the ponds dry, typically in July (Galán, unpubl. data).

On 12 Jan 2006, at a rain pool (340 × 210 cm; max depth 12 cm; 11 m from the sea) with a rock bottom and 30% of its surface covered with vegetation formed by submerged *Paspalum vaginatum* and small *Armeria maritima* and *Ulex europaeus* shrubs at the edge, where *D. galganoi* larvae were found, one could observe a turnstone (*Arenaria interpres*) pecking at the edge (1230 h). This bird was observed with binoculars, verifying that it was capturing *D. galganoi* larvae with its beak. The turnstone scoured the periphery of the pool, submerging its head to a depth of 4–6 cm to capture larvae. On other occasions, it lifted up the submerged vegetation with its beak, capturing larvae that it found among the submerged stalks. At 1330 h, two turnstones were observed feeding in the same way at this pool and two other nearby ones of similar size, where there were also *D. galganoi* larvae. The density of *D. galganoi* larvae decreased in the pools where the turnstones fed, from an average of 350 larvae per m^2, estimated the previous day, to 62 larvae per m^2 after the predation.

This species of turnstone occupies the coastal cliffs in northern Spain from August until March, where it is a common wintering bird (Cramp and Simmons 1983. The Birds of the Western Paleartic. Vol. 3. Waders to Gulls. Oxford University Press, Oxford. 913 pp.; Díaz et al. 1996. Aves Ibéricas. Vol. 1. No Paseriformes. J. M. Reyero Ed., Madrid. 303 pp.; Penas-Patiño et al. 2004. Guía das Aves de Galicia. 2nd ed. Bahia Ed., A Coruña. 463 pp.). Its diet includes insects, mollusks, crustaceans, plant matter, fish, and carrion; amphibians are unrecorded (Cramp and Simmons 1983, *op. cit.*; del Hoyo et al. 1996. Handbook of the Birds of the World. Vol. 3. Hoatzin to Auks. Lynx Ed., Barcelona. 821 pp.). It frequently gets its food in tidewater pools formed in the rocks of the cliffs and some individuals specialize in certain prey types (Cramp and Simmons 1983, *op. cit.*).

Northwest Spain is one of the few areas where *D. galganoi* and *A. interpres* can be found together. This is true both in terms of location (coastal cliff pools) and time (the reproduction period of the *D. galganoi* and the wintering period of *A. interpres* overlap). Therefore, it seems logical that a bird with an opportunistic winter diet would consume amphibian larvae found near the seacoast.

Submitted by **PEDRO GALÁN**, Departamento de Bioloxía Animal, Bioloxía Vexetal e Ecoloxía, Facultade de Ciencias, Universidade da Coruña, Campus da Zapateira, s/n. 15071-A Coruña, Spain; e-mail: pgalan@udc.es.

ELEUTHERODACTYLUS RIDENS (Pygmy Rainfrog). **PREDATION**. Workers of the large ponerine ant *Paraponera clavata* typically forage on small to medium-sized arthropods or collect pieces of plants or nectar (Janzen and Carroll 1983. Univ. Chicago Press, pp. 752–753.) but have been suspected of predating small vertebrates (Fritz et al. 1981. Biotropica 13[2]:158–159). Under experimental conditions (Fritz et al. 1981, *op. cit.*) individual *Paraponera* have been shown to sting and kill unidentified *Eleutherodactylus* that were restrained and presented to these ants. Here we present the first record of *P. clavata* potentially predating on *Eleutherodactylus ridens* under natural conditions.

At 0845 h on 6 Dec 2005, TE observed a single *P. clavata* transporting a dead adult male *E. ridens*. This observation was made in primary forest near Selva Verde Lodge in the vicinity of Guaria, Heredia Province, Costa Rica (10°26'59.6"N, 84°04'02.3"W). The insect was found on a leaf of a ca. 50 cm high plant (Maranthaceae), holding the already dead *E. ridens* in its mandibles and maneuvering its prey through the vegetation. It is possible that a recently dead individual was scavenged, although it is more likely that the ant stung and killed the frog, as Fritz et al. (*op. cit.*) demonstrated that the sting and powerful poneratoxins of *P. clavata* are sufficient to kill *Eleutherodactylus* spp. *Eleutherodactylus ridens* is abundant in the area (TL, pers. obs.) and is commonly found sleeping on low vegetation during the day, primarily relying on crypsis to avoid detection by predators and only fleeing when the leaf it is resting on is moved by a potential predator (TAL, pers. obs.). Foraging *P. clavata* would be able to readily approach and attack sleeping *E. ridens* as their small size and low body weight would not trigger an escape response by the frog.

Photographs of this event have been deposited in the media collection of the Division of Vertebrate Zoology at the Yale Peabody Museum of Natural History (YPM HER M 1142–43).

HYLA ARENICOLOR (Canyon Treefrog). **DIET**. Although there have been several recent studies on various aspects of the ecology of *Hyla arenicolor* (e.g., disease, Bradley et al. 2002. J. Wildl. Dis. 38:206–212; parasites, Goldberg et al. 1996. J. Parasitol. 82:833–835, Sladky et al. 2000. J. Zoo. Wildl. Med. 31:570–575, Jung et al. 2000. Herpetol. Rev. 32:33–34; thermoregulation and water economy, Preest et al. 1992. Herpetologica 48:210–219, Snyder and Hammerson 1993. J. Arid. Environ. 25:321–329), there are few, if any, reports on its diet. Here we report observations on the stomach contents of six *H. arenicolor* collected during 2003 and 2004 from Milpillas, Municipio Chínipas, Chihuahua (N = 1; 27°12'9.7"N, 108°38'47.3"W; WGS 84; 1259 m elev.), Huisivo, Chihuahua (N = 1; 27°23'39.9"N, 108°32'36.0"W; WGS 84; 469 m elev.); km 17 Creel-San Rafael, Municipio Urique, Chihuahua (N = 1; 27°40'1.1"N, 107°44'42.7"W; WGS 84; 2233 m elev.), and Yécora, Sonora (N = 3; 28°22'4.0"N, 108°55'32.6"W; WGS 84; 1545 m elev.) (see Lemos-Espinal et al. 2004. Bull Chicago Herpetol. Soc. 39:107–109; Smith et al. 2005. Bull Chicago Herpetol. Soc. 40:45–51). All six individuals contained identifiable stomach contents. The diet of *H. arenicolor* contained a fairly large diversity of organisms (Table 1). Numerically, termites and beetles were the most important prey, but volumetrically, beetles and orthopterans were most important.

TABLE 1. Stomach contents of 6 *Hyla arenicolor* from Chihuahua and Sonora, México.

LEPTOBRACHIUM SMITHI (Smith's Litter Frog). **ANTIPREDATOR BEHAVIOR**. *Leptobrachium smithi* is a megophryid frog described from "Ton Nam Plu Waterfall" Khao Chong, Trang Province, southern Thailand (7°34'N, 99°49'E, 260 m elev.) (Matsui et al. 1999. Japan J. Herpetol. 18:19–29). Distribution includes Thailand, Myanmar, India, Bangladesh, and Laos (Nabhitabhata et al. "2000" [2004]. Checklist of Amphibians and Reptiles in Thailand. Office Environmental Policy and Planning. 152 pp.; Das et al. 2004. Asiatic Herpetol. Res. 10:245–246;

FIG. 1. An adult male *Leptobrachium smithi* exhibiting antipredator behavior.

Sengupta et al. 2001. J. Bombay Nat. Hist. Soc. 98[2]:289–291; Asmat et al. 2003. Univ. J. Zool. 22:141–143; Stuart 2005. Herpetol. Rev. 36:473–479). Defensive behavior in *L. smithi* has not been reported previously.

On 30 June 2006, an adult male *L. smithi* was collected as it called in hilly evergreen forest (47 Q 0700022, UTM 1834963, 714 m elev.) at Nong Mae Na Protected Unit of Thung Salaeng Luang National Park, Khao Khor District; Phetchabun Province by Y. Chuaynkern and C. Inthara. While being manipulated for photographs, the frog assumed an antipredator behavior when touched near the vent. The individual arched its back with its head elevated ca. 90°, the eyes were bulged which prominently displayed the contrasting orange and black eye color (Fig 1). The limbs were outstretched and the frog remained motionless. A somewhat similar behavior is well known in *Bombina variegata*, with the frog resting on its belly, the chin elevated, and the bright orange palms and soles of the feet upturned (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill Book Co., New York. 670 pp.).

Fieldwork was financed by a grant to PD from the Office of Environmental Policy and Planning (OEPP), and permitted by the National Park, Wildlife, and Plant Dept., Ministry of Natural Resource and Environment (Thailand). We thank Thaweesak Kaentong and Panya Chanma (Nong Mae Na Protected Unit, Thung Salang Luang National Park) for the assistant in the field.

LEPTODACTYLUS MELANOTUS (Sabinal Frog). **DIET**. Little is known about the ecology of *Leptodactylus melanotus*. Here we report observations on the stomach contents of seven *L. melanotus* collected during 2004 from Río Mayo at the gates of Presa Mocuzari, Sonora, México (27°13'25.6"N, 109°6'30.6"W; WGS 84; 90 m elev.) (see Smith et al. 2005. Bull Chicago Herpetol. Soc. 40:45–51). Of the seven individuals, five contained identifiable stomach contents, one contained unidentifiable stomach contents, and one had an empty stomach. Table 1 lists the prey items. Numerically, beetles and collembolans were the most important prey items, but volumetrically beetles were the most important.

TABLE 1. Stomach contents of *Leptodactylus melanotus* from Sonora, México.

Prey Type	Prey Items N	(%)	Volume cm^3	(%)	Number of Stomachs

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog). **DIET**. Anurans are generally cited as the prey and not the predators of aeshnid dragonflies (Buskirk 2000. Ecol. 81:2813–2821; Caldwell et al. 1980. Oecologia 46:285–289). Dragonflies have been occasionally recorded in *Osteopilus septentrionalis* diet (0.6 % of stomachs examined), but the species taken were not identified (Meshaka 2001. The Cuban Treefrog in Florida. Univ. Press Florida, Gainesville. 192 pp.). Here we document the first observation of *O. septentrionalis* preying on the dragonfly *Anax junius* (Green Darner).

Osteopilus septentrionalis and *A. junius* have been observed on many occasions to perch on the window shutters of the Environmental Learning Center at Rookery Bay National Estuarine Research Reserve, Collier County, Florida, USA. At ca. 1130 h on 14 July 2006, TMB observed an adult female *O. septentrionalis* (6.4 cm SVL) capture and eat an adult (7.8 cm TL) female *A. junius*. Conditions at the time were hot (33°C) and humid (65% RH), with light wind (5 mph), high pressure (1018.6 mb) and overcast. The treefrog lunged at the dragonfly with its mouth open and its tongue pad protracted. The dragonfly was captured sideways, and its wings and abdomen protruded from the treefrog's mouth. Subsequently, the treefrog used its forelimbs to push the prey headfirst into its mouth. Handling time was ca. 15 min. The treefrog was immediately captured, and subsequent dissection revealed a rapid digestion of the *A. junius* abdomen and no other prey within the stomach, few fat bodies, and a nearly gravid reproductive status.

Osteopilus septentrionalis is a sit-and-wait predator capable of eating very large prey (Meshaka 2001, *op. cit.*). The wide variety of prey items in the diet of *O. septentrionalis* indicates that it is not a specialized feeder, but Coleoptera and Blattaria are the prevailing categories of items in stomach contents (Meshaka 2001, *op. cit.*). *Anax junius* is one of the largest (60–80 mm) dragonflies in South Florida (Dunkle 1989. Dragonflies of the Florida Peninsula, Bermuda, and the Bahamas. Gainesville, Florida, Scientific Publishers. 154 pp.). The geographic range of *A. junius* overlaps with that of *O. septentrionalis*. Although it is unlikely to be preyed upon by the smaller native treefrogs, the depredated individual was ca. 122% of the predator's body length, and average body sizes of female *O. septentrionalis* exceeding 6 cm are typical of Florida populations (Meshaka 2001, *op cit.*). Furthermore, the *O. septentrionalis* was yolking and had little fat development. Thus, it would seem that in chance encounters between these species on sultry days or near dusk, even large *A. junius* are susceptible to the depredations of *O. septentrionalis*, and in turn mature females are provided with a nutritious meal.

MESHAKA**, State Museum of Pennsylvania, 300 North Street, Harrisburg, Pennsylvania 17120-0024, USA (e-mail: wmeshaka@state.pa.us).

PLEURODEMA NEBULOSA (NCN)**. REPRODUCTION.** *Pleurodema nebulosa* occurs in the arid areas of western Argentina, from Catamarca to Rio Negro (Cei 1980. Amphibians of Argentina. Monit. Zool. Ital. [NS]. Monogr. 2, 609 pp.). Herein we present the first data on the reproductive ecology of *Pleurodema nebulosa* in Argentina. Our study area was located 40 km N of San Juan City on National Route N40. This area is in the Monte Phytogeographic Province (Cabrera and Willink 1980. Biogeografía de América Latina. O.E.A. Washington, DC. 109 pp.). Dominant vegetation includes *Prosopis* sp., *Bulnesia retama*, *Solanum eleagnifolium*, *Caparis atamisquea*, *Grabousquia obtusa*, and *Tamarix gallica*.

Individual male and female *P. nebulosa* were captured by hand after heavy rains occurred in the area on 17–18 and 20 Jan 2004. Ovarian mass was determined by weighing to 0.001 g. The number of mature ova was calculated by counting a subset of the entire mass, and ova diameter was measured to 0.02 mm under a binocular magnifying glass. Testicular volume was calculated using the formula for an ellipsoid sphere (Dunham 1983. *In* Huey et al. [eds.], Lizard Ecology, pp. 261–280. Harvard Univ. Press, Cambridge, Massachusetts).

The mean number of mature ova was 547 (SD = 318.3, range = 175–962, N = 11); mean ova diameter was 0.91 mm (SD = 0.13, range = 0.74–1.2 mm, N = 11). As female size increases so does fecundity, i.e., the number of ovules produced increases ($R^2 = 0.55$, $p < 0.0059$). Mean testicular volume was 2.39 mm^3 (SD =1.36, range = 0.55–5.8 mm^3, N = 22). A positive and significant relationship exists between testicular volume and SVL ($R^2 = 0.54$, $p < 0.00005$) and between testicular volume and mass of the individuals ($R^2 = 0.57$, $p < 0.00002$).

Submitted by **EDUARDO A. SANABRIA, LORENA B. QUIROGA** and **JUAN C. ACOSTA,** Departamento de Biología e Instituto y Museo de Ciencias Naturales, Facultad de Ciencias Exactas, Físicas y Naturales, Universidad Nacional de San Juan, Avenida España 400 (N), Caixa Postal 5400, San Juan, Argentina; e-mail (EAS): sanabria_eduardo@hotmail.com; e-mail (JCA): jcacosta@sinectis.com.ar.

PLEURODEMA TUCUMANA (NCN). **REPRODUCTION.** *Pleurodema tucumana* is a small leptodactylid frog that occurs in northern and west-central Argentina (Lavilla et al. 2000. Categorización de los Anfibios y Reptiles de la República Argentina. Asoc. Herpetol. Arg. 97 pp.). Information on the species is restricted to preliminary data on reproduction (Perotti 1997. Rev. Chilena Hist. Nat. 70:277–288). Herein, we report the first reproductive data of the species from Chaco Phytogeographic Province, Distrito Chaco Serrano in western Argentina (Cabrera and Willink 1980. Biogeografía de América Latina. O.E.A. Washington D.C. 109 pp.).

We collected 30 *P. tucumana* (20 males and 10 females) from the Las Tumanas River (30°52'S, 67°19'W. 750 m elev.), Valle Fértil Department at 137.5 km from San Juan city during January 2000. Flora at the study site was dominated by *Schinopsis haekeana* and *Aspidosperma quebracho-blanco*. Frogs were captured by hand, preserved, and deposited in the Facultad de Ciencias Exactas, Físicas y Naturales of the Universidad Nacional de San Juan Collection (MCN-UNSJ4100-4129).

Mean SVL of males (N = 20) was 32.7 mm (range 27–35 mm; SD 1.68 mm), mean body mass was 3.34 g (1.18–4.96 g; SD 0.82 g), and mean testicular volume was 0.83 mm^3 (0.31–1.27 mm^3; SD 1.44 mm^3). SVL was not associated with testicular volume ($r_s = -0.025$; $p = 0.91$) nor body mass ($r_s = 0.16$; $p = 0.49$).

Mean SVL of gravid females (N = 10) was 37.3 mm (range 36–39 mm; SD 1.05 mm), mean body mass was 5.16 g (3.37–6.77 g; SD 1.07 g), mean mature ovum count was 993 (255–2933; SD 838), mean mature ovum diameter was 0.68 mm (0.04–0.98 mm; SD 0.37 mm), mean ovary mass was 0.33 mg (0.04–1.1 mg; SD 0.33 mg), and mean factor of ovarian size was 22.2 (0.29–34.1; SD 22.8). The mature ovum count was not correlated with SVL ($r_s = 0.33$, $p = 0.35$) nor body mass ($r_s = 0.56$, $p = 0.08$). There was a significant relationship between mature ovum diameter and mature ovum count ($r_s = 0.74$, $p = 0.01$). The ovary mass averaged 6.8% of the body mass in females.

The reproductive data presented herein for *P. tucumana* from Chaco serrano is similar to that from Chaco semiarid (Perotti 1997, *op. cit.*).

RANA CATESBEIANA (American Bullfrog). **DIET**. On 27 Aug 2006, three adult *R. catesbeiana* were collected from Big Muskego Lake (42°51.241'N, 88°07.456'W), Muskego, Waukesha County,

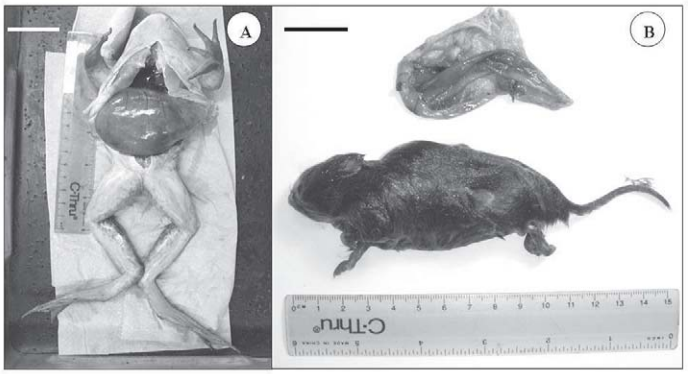

FIG. 1A. Adult male *Rana catesbeiana*; note the distended stomach. Bar = 40 mm. 1B. Adult male meadow vole, *Microtus pennsylvanicus*. Bar = 25 mm.

Wisconsin, USA. Frogs were captured by hand with the help of a headlamp (ca. 030 h). All frogs were euthanized and SVL and gape size were recorded to the nearest mm for each individual. The stomach, small intestine, and large intestine were removed, and the stomach was separated from the rest of the gastrointestinal tract. Each stomach was opened and contents examined under a dissecting microscope. A male *R. catesbeiana* (SVL 13.5 cm; gape size 5.2 cm) had a greatly distended stomach (Fig. 1a), which contained a small mammal (Fig. 1b). The two other specimens had empty stomachs.

The mammal was identified as an adult male meadow vole, *Microtus pennsylvanicus* (Jackson 1961. Mammals of Wisconsin. Univ. Wisconsin Press. 504 pp.). The vole was 11.5 cm in total length; 4.8 cm tail length; hind foot 20 mm with six plantar tubercles; was dark brown above, and somewhat paler below with short ears (length 11 mm from notch). Few reports exist on species identification of small mammals in bullfrog stomachs (Lannoo 2005. Amphibian Declines. The Conservation Status of United States Species. University of California Press, Berkeley. 1094 pp.), and no reports exists of *R. catesbeiana* feeding on small mammals in Wisconsin (Vogt 1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, and Friends of the Museum, Inc., Milwaukee, Wisconsin, 205 pp.).

We thank M. and G. Bolek for allowing access to the field site, S. Gardner, T. Haverkost, D. Tinnin, and A. Jiménez-Ruiz, Harold W. Manter Laboratory of Parasitology, Univ. Nebraska State Museum, for identification of the meadow vole, and M. Bolek for comments on the manuscript.

RANA YAVAPAIENSIS (Lowland Leopard Frog). **REPRODUCTION**. *Rana yavapaiensis* typically exhibit a bimodal breeding season in Arizona. Most reproductive activity occurs in early spring (February–April), with a second season of lesser activity in late September and October (Sartorius and Rosen 2000. Southwest. Nat. 45:267–273). In Arizona, winter months are generally periods of relatively low activity with no reports of reproductive behavior (Sredl 2005. *In* Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 596–599. Univ. California Press, Berkeley, California). The only documented January reproduction in *R. yavapaiensis* was at –38 m elev. in the Coachella Valley, California (Ruibal 1959. Copeia 1959:315–322; reported as *Rana pipiens*).

On 29 Dec 2005, 2115 h, at Walnut Springs, a tributary to the Verde River, Mazatzal Mountains, Maricopa County, Arizona (UTM 3750734N, 451734E, NAD 27, 1119 m elev.), JBV observed an amplexing pair of *R. yavapaiensis* and heard several adult males calling. On 6 Jan 2006, there were two freshly laid *R. yavapaiensis* egg masses in the spring pool. We believe this is the first report of reproductive activity in mid-winter (December or January) in Arizona. Walnut Springs is a thermally stable system (T_w = 17°C on 29 Dec 2006) and perhaps provides a suitable microhabitat for successful winter breeding. Therefore, reproductive patterns in *R. yavapaiensis* might be more labile than previously thought, depending on local conditions.

SMILISCA FODIENS (Lowland Burrowing Treefrog). **DIET**. Little is known about the ecology of *Smilisca fodiens* beyond reports of its distribution (Sullivan et al. 1996. Great Basin Nat. 56:38–47), endoparasites (Goldberg et al. 1999. Great Basin Nat. 59:195–197), cocoon formation (Ruibal and Hillman 1981. J. Herpetol. 15:403–408), and metabolism (Taigen et al. 1982. Oecologia 52:49–56). To our knowledge there have been no reports on its diet. Here we report observations on the stomach contents of 15 *S. fodiens* collected during 2004 from Valle de Tacupeto, Sonora, México (28°15'20.5"N, 109°18'1.9"W; WGS 84; 435 m elev.) (see Smith et al. 2005. Bull Chicago Herpetol. Soc. 40:45–51). Of the 15 individuals, nine contained identifiable stomach contents, five contained unidentifiable stomach contents, and one had an empty stomach. Table 1 lists the prey items. Numerically and volumetrically, beetles were the most important prey, followed by orthopterans. Beetles were found in seven of the nine stomachs containing identifiable stomach contents. It seems that the diet of *S. fodiens* at this site is made up primarily of beetles.

TABLE 1. Stomach contents of *Smilisca fodiens* from Sonora, México.

Prey Type	Prey Items N	Prey Items (%)	Volume mm^3	Volume (%)	Number of Stomachs
Coleoptera	17	(70.8)	3.26	(56.4)	7
Hymenoptera (ants)	4	(16.7)	1.20	(20.8)	2
Lepidoptera	1	(4.2)	0.08	(1.4)	1
Orthoptera	1	(4.2)	0.21	(3.6)	1

TESTUDINES

ACTINEMYS MARMORATA (Pacific Pond Turtle). **EGGS**. As with nearly all turtles, *Actinemys marmorata* typically deposits its eggs in a terrestrial, excavated nest (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington DC, 578 pp.). On 11 August 2006, six eggs of *A. marmorata* were found submerged in a natural pool (4 m long, 2.5 m wide, and 0.8 m deep) along a tributary of Adobe Creek, Sonoma County, California, USA. The six eggs were not damaged or predated and were located under water 12 cm deep within 30 cm of the shoreline. The eggs were slightly dispersed from each other. Most eggs had a slight silt deposit on the shell, suggesting that the eggs were not recently deposited. At this pool two *A. marmorata* adults had been observed basking on a log three weeks earlier. There were no signs of depredated turtle nests around the bank of the pool.

Weight and size of eggs: 11.3 g, 35.4 mm (total length), 22.9 mm (largest width); 12.3g, 36.4 mm, 23.9 mm; 10.8 g, 35.4 mm, 22.9 mm; 12.9 g, 36.4mm, 24.9 mm; 10.1g, 34.3 mm, 23.9 mm; 11.7g, 36.4 mm, 22.9 mm. Mean weight was 11.5 g, and mean length 35.7 mm, and width 23.6 mm.

ACTINEMYS MARMORATA (Pacific Pond Turtle) and ***TRACHEMYS SCRIPTA ELEGANS*** (Red-eared Slider). **REPRODUCTIVE BEHAVIOR**. Attempted mating between native and introduced turtle species in the wild rarely has been documented (e.g., Ernst et al. 1994. Turtles of the United States and Canada, Smithsonian Inst. Press, Washington, D.C.), let alone between different genera. Although there have been several observations of aggressive behavior between Pacific Pond Turtles (*Actinemys marmorata*) and various species of sliders (*Trachemys* spp.), mostly in association with competition for prime basking sites (Spinks et al. 2003. Biol. Cons. 113:257–267), this is apparently the first documentation of attempted mating between the two.

On 9 May 2005, one of us (BML) observed an attempted mating between a male Pacific Pond Turtle and a female Red-eared Slider (*Trachemys scripta elegans*). The observation occurred along Oso Creek in the City of Mission Viejo, south Orange County, California (USA). Habitat consisted of a large pool formed at the base of a rip rap outflow structure where 1.2-m corrugated metal pipes conduct stream flow under the Interstate 5 freeway. Large willow (*Salix* sp.) and Western Sycamore (*Platanus racemosa*) trees overhang a portion of the pool partially shading the area. Several partially submerged rocks (riprap) and emergent logs provide suitable basking sites. The source of water is primarily urban runoff, with residential developments and a golf course along Oso Creek immediately upstream (on the other side of the freeway).

At approximately 0900 h, the two turtles were observed swimming together parallel to the edge of the pool, with the male Pond Turtle swimming on top of the female Slider, his head and legs fully extended. The female appeared to be intentionally moving away from the male, and moved out of the water onto the shore, with the male partially on her back. The male continued his pursuit of the female, mounting and balancing on the carapace of the female while they were out of the water. At this time the male was continuously probing the tip of his tail back and forth along the posterior edge of the female's plastron attempting copulation (at which he appeared to be successful). The female finally returned to the water and the male slid off her back as she swam away. The entire encounter lasted approximately two to three minutes and was photographed with a hand-held, digital camera.

Only two adult male *A. marmorata* were observed in the habitat during a total of eleven visits to the site through the spring and summer of 2005; the second male was observed basking in a pool approximately 300 m downstream. Because Pacific Pond Turtles are relatively long-lived (Jennings and Hayes 1994. Amphibian and Reptile Species of Special Concern in California. California Dept. of Fish and Game, Inland Fisheries Division, Contract No. 8023. 255 pp.), adults may persist for many years in degraded, human-modified habitats where upland habitat suitable for egg deposition is absent, resulting in an adult-biased age structure (Jennings and Hayes, *op. cit.*). It is possible that the Oso Creek population at this location has been reduced to two adult males, and the attempted mating by the male only occurred because conspecific female turtles were unavailable.

ACTINEMYS* (=*CLEMMYS*) *MARMORATA MARMORATA (Northwestern Pond Turtle). **COURTSHIP BEHAVIOR.** Courtship behavior of the southern subspecies *A. m. pallida* has been observed in the field in May, June, and late August and in captivity in late August and early September (Buskirk 1991. *In* Beaman et al. [eds.], Proceedings of the First International Symposium on Turtles and Tortoises: Conservation and Captive Husbandry, pp. 16–23. Chapman University, Orange, California; Goodman 1997. The Biology of the Southwestern Pond Turtle [*Clemmys marmorata pallida*] in the Chino Hills State Park and the West Fork of the San Gabriel River. Master's thesis, California State Polytechnic University, Pomona, California; Holland 1988. Herpetol. Rev. 19:87–88). Here I provide a detailed description of the courtship behavior of *A. m. marmorata* observed in the wild, and note the timing of two other observations of probable courtship behavior.

At 1215 h on 19 September 2003, while snorkeling in the south

fork of the Trinity River near Hyampom, California (UTM 465160E, 4474972N), I observed two *A. m. marmorata* engaged in presumed courtship activity. I was floating near the left bank, hidden by overhanging vegetation, where I had a clear view of two turtles below without them noticing me. The water was clear and sunlit from directly overhead, and visibility was excellent. Water temperature was 15.3°C and air temperature was 23.4°C.

Both turtles were adults, of similar size, and the genders were easily discerned from standard dimorphic characters. The female was resting on the bottom of the pool on sandy substrate. She was orientated away from the left bank with her head and forelimbs retracted beneath the carapace. Her hind limbs were partially extended and in firm contact with the substrate. The male was facing the female, scratching the anterior of her carapace with the claws of his forelimbs. He would first scratch three times with the left forelimb, three times with the right, then three times with both forelimbs simultaneously, and then repeat this cycle. The scratching was usually in sets of three. He did this for about a minute then he reared up on his hind limbs with his anterior raised off the substrate at about a 45° angle and waved both forelimbs side to side in a symmetrical manor for 10–15 seconds. This action seemed to push him up and backward until he was nearly vertical on his hind limbs. Then he would stop waving, settle back down to the bottom of the pool in front of the female, and within a few seconds, resume scratching on her carapace following the same pattern as previously described. He went through this cycle of scratching and front limb waving three times. After a few minutes of this behavior the female extended her head and forelimbs, turned approximately 120° to the left, and began walking downstream. The male quickly followed. The female only moved about 2 m downstream before he swam over the top of her carapace and settled down in front of her, again face to face, blocking her forward movement. She tucked back into her shell, in the same position previously described, with hind limbs extended like braces. The male immediately began the scratching behavior, again following the same pattern of threes. This lasted for several minutes, until the female's head protruded from under her carapace and she suddenly turned 180° and began to walk quickly upstream as if attempting to flee the male. The male followed and swam up over her and settled down on the substrate facing her, again blocking her forward progress. At this point the two turtles were directly below me at about 1.5 m in depth. The male once again resumed the scratching and waving behavior, but during the first bout of waving the female looked up, appeared to see me and immediately fled, swimming along the bottom towards the middle of the river and deeper water. The male watched her flee, but did not follow. She took refuge beneath large submerged boulders near the deepest part of the river (ca. 5 m away and 5 m deep). Once the female was out of sight, the male slowly turned and began to swim toward the surface as if surfacing to breathe. He came straight up towards me in a relaxed manor. At about 30 cm from my face mask, he looked straight at me, paused a second, then fled rapidly to the deep water mid-channel. He went under a boulder about 3 m from the female's retreat. Although I had remained motionless during the encounter to avoid detection and thus did not consult my wristwatch for exact timings, the entire observation lasted approximately 8 minutes.

In late May, 1994, I briefly observed a similar interaction on the mainstem of the Trinity River near Junction City, California, but in this instance the male turtle noticed my presence in less than a minute and both turtles attempted to flee. Similar courtship behavior was observed by James Bettaso (USFWS) in the South Fork Trinity River, near the confluence of Surprise Creek near dusk on 28 September 2005. Observations of courtship behavior in both spring and fall are consistent with previous reports.

CHELODINA* sp.** (Kimberley Long-necked Turtle) and ***EMYDURA AUSTRALIS (Northwest Red-faced Turtle). **PREDATION**. Freshwater turtles have been noted as prey taken by pelicans, jabirus, hawks, sea eagles, and wedge-tail eagles (Worrell 1966. Australian Snakes, Crocodiles, Tortoises, Turtles, and Lizards. Angus and Robertson, Sydney). However, published life history data that quantify turtle species, number, and size classes taken by avian predators are lacking. Here we report on predation by White-bellied Sea Eagles (*Haliaeetus leucogaster*) on two turtle species of inland rivers in northwestern Australia.

During turtle surveys of the Kimberley Plateau (by ADT and NNF) in June 2006, residents from Tirralintji Station (SW, BW) reported carcasses of freshwater turtles predated by White-bellied Sea Eagles at the Traine River (-17.198°S, 126.436°E). A partial carcass of *Chelodina* sp. (reconstructed straight-line carapace length [SCL] estimated at 18 cm) was beneath an eagle nest on the southern bank. Beneath a feeding station tree on the northern bank were shells of four *Chelodina* (16.4, 18.8, 19.1, 19.8 cm SCL) and one *Emydura australis* (16.2 cm SCL). Voucher specimens were deposited with the Western Australia Museum (specimen numbers pending). Several carcasses had injuries to the anterior carapace as described for bird-predated adult *Chelodina rugosa* reported by Cann (1989. Australian Freshwater Turtles. Beaumont Publ. Pty. Ltd, Singapore).

The lengths of these predated turtles was compared to the size range of turtles trapped from the same pool and a nearby section of the Traine River (-17.195°S, 126.456°E). The trapped sample of *Chelodina* sp. ranged from 18.0 to 21.3 cm SCL (N = 3) and *E. australis* ranged from 12.9 to 22.3 cm SCL (N = 23). The carcass sizes reported here are similar to lengths of carcasses recovered at sea eagle nests at other inland and coastal locations (Clark 1982. J. Field Ornithol. 53:49–51; Mitchell et al. 2006. Herpetol. Rev. 37:216–217; Woodall 1982. Sunbird 12:11–14). Taken together, these observations suggest that small freshwater turtles generally comprise a minor dietary resource of large coastal raptors.

Tirralintji residents observed that the sea eagles reside locally only for nesting, and migrate elsewhere after the young fledge. The billabong is from 190 to 275 km distant from coastal areas near Flatback Turtle (*Natator depressus*) nesting and/or developmental habitats. Given that sea eagles are identified predators of juvenile Flatbacks (Walker 1991. Mar. Turt. Newsl. 55:6), two speculative scenarios may apply—foraging tactics developed for juvenile Flatback Turtles at sea would facilitate switching to similar-sized freshwater turtles, or the opposite scenario. Tirralintji residents noted that eagle predation occurred during the late dry season (September–November) when turtles often migrate over-

land from drying billabongs to permanent pools. Further observations will be necessary to determine whether turtle predation by eagles is a localized phenomenon due to unique site characteristics at the pool, or possibly represents opportunistic scavenging.

We thank Earthwatch Institute, Australia for funding and field volunteers. Specimens were collected with permission of the Australian Wildlife Conservancy (property owners and managers) and also the Tirralintji community (traditional owners). Fieldwork was facilitated by T. Vigilante of Kimberley Land Council and S. Legge of Australian Wildlife Conservancy. J. Mitchell and R. Welsh gave helpful critique on an early draft. Surveys were covered by animal ethics board approval of the University of Canberra and collecting permit SF5344 from the Department of Conservation and Land Management, Western Australia.

CHELUS FIMBRIATUS (Matamata). **REPRODUCTION.** On 21 September 2006 we found a clutch of *Chelus fimbriatus* eggs in the Caño Guaritico, at the Estación Biológica El Frío (Apure, Venezuela; UTM: 0508375 N; 0872150 W). The ten egg clutch was found at the edge of the stream (7 cm above the water level), inside a hole excavated by fishes locally called "bagres" (Loricariidae: *Hypostomus plecostomus*, *Liposarcus multirradiatus*, and *Glyptoperichthys gibbiceps*). The hole was partially collapsed by stream flow, which allowed us to find the clutch. There were no signs of depredation. The eggs were transferred to a polyurethane box filled with sand and taken to the biological station. The eggs were spherical, with a smooth, white shell. Egg diameter in this clutch ranged from 37.8 to 39.4 mm (mean 38.4 mm); egg mass ranged from 33.5 to 36.5 g (mean 34.9 g). Although the deposition date of this clutch is unknown, it is earlier than most previous reports, such as October in Colombia (Medem 1969. Caldasia 8:341–351) and October–November in Venezuela (González Ortiz, in Mondolfi 1955. Memorias Sociedad Ciencias Naturales La Salle 15:177–183; Lasso, pers. obs.). This report is apparently the earliest date for a clutch of *Chelus fimbriatus* in the wild, although in all cases the reported dates for egg laying coincide with decreasing water levels at the start of the dry season.

Clutch size reported here is smaller than clutches reported by Medem (*op. cit.*), Mondolfi (*op. cit.*) and Hausmann (1968. Int. Turt. Tort. Soc. J. 2[4]:18–19, 36), who note a range of 12–28 eggs. Our egg size data agree with those compiled by Pritchard and Trebbau (1984. Turtles of Venezuela, SSAR, Ohio), who reported that egg diameter ranged from 3.4 to 4.0 cm.

We thank Javier Castroviejo, Ramón Nieves, and Franklyn Silva for field assistance, and Julio García for helping with translation.

CHRYSEMYS PICTA BELLII (Western Painted Turtle)**. COLORATION**. Variations in pigmentation, independent of subspecies characteristics, have been observed in many indigenous populations of *Chrysemys picta* throughout North America. These variations have been attributed to a number of biotic and abiotic factors such as sexual cycles, age, differences in habitat quality such as minerals or tannins in the water, or variable substrate colors (Rowe et al. 2006. Herpetol. Rev. 37:293–298). Here we report the first published account of reticulate blue coloration in *C. picta*. On 9 September 2005, we captured a large male *C. picta bellii* (171 mm PL) in an irrigation ditch adjacent to the South Platte River in Brush, Colorado (Morgan County). In addition to the usual red and black markings, this individual displayed distinct blue reticulate coloration along the marginal scutes. This coloration was especially striking on the inframarginal scutes and bridge. These reticulate blue marking appeared to have completely replaced the yellow markings typically found on these scutes. On 28 May 2006, two other *C. picta* males (141 mm and 142 mm PL) displaying similar blue coloration, were captured in a small pond near Limon, Colorado (Elbert County) ca. 160 km S of the Morgan County location. Although reticulate melanism is well documented for older males of this subspecies (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington DC. 578 pp.), it is not known if the blue reticulation pattern follows a similar pattern of expression. To date, no females have been discovered with similar coloration. Differences in habitat quality and distance between these two locations make it unlikely that environmental conditions alone would account for this unusual color pattern.

CYCLEMYS DENTATA (Asian Leaf Turtle). **FIRE SCARS**. On 25 November 2004, during a larger study on freshwater turtles in Loagan Bunut National Park (LBNP) (03°44'–03°N, 114°09'–114°17'E), Sarawak, Malaysia, a small adult *Cyclemys dentata* (straight carapace length 130 mm) was collected, measured, and released. On the left side, marginals III–VII were damaged; scutes were partially missing, and portions of marginals V–VII missing (Fig. 1). All edges of the remaining portions of the marginals appeared to have undergone trauma presumably from exposure to fire. The injury was not new and had apparently healed.

Cyclemys dentata is known to occur in both highlands and, more commonly, in lowlands near small streams and ponds throughout Southeast Asia. Out of five individuals located at LBNP, all but one were found in secondary forest and the burnt individual was found on the eastern edge of the park, near an oil palm plantation. Fire is a common, yet controversial, tool used in the region to quickly clear brush and weeds for planting, particularly on oil palm and pulp wood plantations (Kinnaird and O'Brien 1998. Conserv. Biol. 12:954–956). Fires are routinely set at or near the end of the southwest monsoon, which corresponds to the dry season, and has

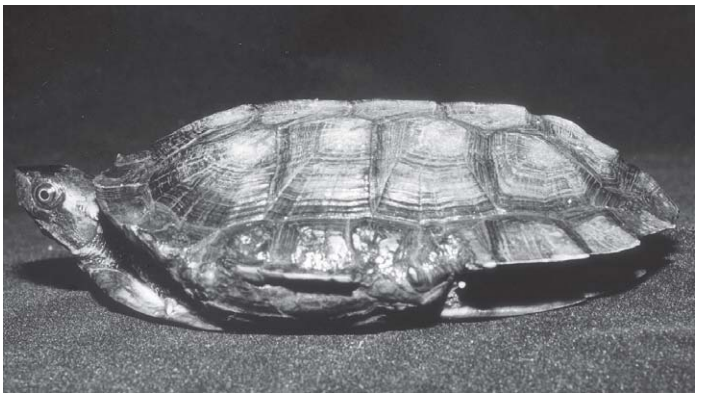

FIG. 1. View of the left aspect of an individual of *Cyclemys dentata* showing scarred and missing marginals.

been known to affect other turtle species in the region (Mitchell et al. 2005. Herpetol. Rev. 36:169).

DERMOCHELYS CORIACEA (Leatherback Seaturtle). **DIET**. Leatherback Seaturtles are dietary specialists, consuming planktonic gelatinous prey such as medusae (Scyphozoa, Siphonophora), salps and pelagic tunicates (Bjorndal 1997. *In* Lutz and Musick [eds.], The Biology of Sea Turtles, pp. 199–232. CRC Press, Boca Raton, Florida). Small quantities of other organisms are sometimes identified in gut contents, such as amphipods, other crustaceans, and fish, thought to have been consumed coincidentally together with commensal jellyfish (Frazier et al. 1985. J. Herpetol. 19:159–160). Here, we report the consumption of two new dietary items for this species

On 5 April 2005, an adult female Leatherback Seaturtle (CCL= 143.0 cm), was found stranded and dead on San Luis Beach, Canelones, Uruguay (34°46'34"S, 55°35'18"W). The turtle was probably captured by a trawling vessel of the Uruguayan fleet, evidenced by a rope tied around its front flippers, used to discard the animal off the ship (Martin Laporta, pers. comm.). We examined the contents of the digestive tract and identified remains of the jellyfish *Lychnorhiza lucerna* (Scyphozoa, Rhizostomeae) and seven spider crabs *Libinia spinosa* (Decapoda, Majidae). The crabs were determined to be juveniles because of the relatively small size of their carapaces (10.8–18.2 mm. length, 8.7–14.5 mm. width, N = 7). Additionally, an adult Weakfish (*Cynoscion guatucupa*) (size = 250 mm) was also found in the esophagus of the turtle.

Lychnorhiza lucerna is a scyphozoan jellyfish that belongs to the Order Rhizostomeae, Superfamily Inescapulatae (Mianzan and Cornelius 1999. *In* D. Boltovskoy [ed.], South Atlantic Zooplankton, pp. 513–559. BACKHUYS Publishers, Leiden). It is common in the region, with a known geographic range that extends from San Clemente del Tuyú, Argentina, north to the Guyanas (Mianzan 1989. Inv. Mar. CICIMAR Vol. 4 nº 1). However, to our knowledge this is the first report of *L. lucerna* consumption by *D. coriacea*. A mutualistic-commensalistic relationship between the spider crab and *L. lucerna* has been documented in Uruguay by Vaz-Ferreira (1969. Bol. Soc. Zool. Uruguay 2:64–66), indicating that the crabs were ingested incidentally with the jellyfish. We believe that the presence of a Weakfish in the turtle's digestive tract is likely to be accidental, and suspect that was ingested while the turtle was captured within the trawl net.

We thank Antonia Bauzá and the local fishermen Cacho and Tincho for their help with the necropsy work. Jack Frazier, Fabrizio Scarabino, and Hermes Mianzan provided literature and comments on earlier drafts. Funding for Karumbé activities at San Luis Field Station came from the BP Conservation Programme. Karumbé field permit nº 200/04 is provided by MGAP-Division Fauna.

ERYMNOCHELYS MADAGASCARIENSIS (Madagascan Sidenecked Turtle). **DIET**. A number of authors (Siebenrock 1903. Abhandlungen der Senckenberg Naturforschenden Gesellschaft 27: 241–259; Vaillant and Grandidier 1910. *In* Histoire Physique, Naturelle et Politique de Madagascar, Paris, Librarie Hachette 17:1–86; Decary 1950. Les reptiles Chapitre III. La faune malgache. Paris: 77–89; Tronc and Vuillemin 1973. Bulletin de l'Academie Malgache, T. 51/1:190–224) described *Erymnochelys madagascariensis* as carnivorous, feeding primarily on molluscs, arthropods, fish, and amphibians. More recent studies (Kuchling and Mittermeier 1987. IUCN SSC 2:121–124; Jenkins et al. 1990. Expedition Final Report, Oxford Univ.: 13 pp.; Kuchling 1993. Salamandra 28:231–250) suggested the species was omnivorous because significant amounts of plant material were found in sampled guts. These authors identified three main components in the turtle's diet; animal matter (mostly made up of the small gastropod, *Melanoides tuberculata*), fish, and green shoots and root-tips of the reed *Phragmites mauritaunicus*. However, these data were collected over short time periods and are not representative of all ages, sizes, or habitats. In 1998–2000 the first author completed a study of the dietary preferences of the species by analyzing stomach contents (stomach flushing: Legler 1997. Herpetologica 33:281–284) and fecal samples of turtles trapped or accidentally collected at Ankarafantsika National Park, Madagascar, as part of his PhD thesis research (García 2005. DICE Institute, University of Kent, Canterbury. 299 pp.). A total of 298 stomach samples from 243 turtles and a total of 499 fecal samples from 72 turtles were collected from seven localities during the study period.

Juvenile and mature turtles differed in percentage animal and plant material identified in gut samples (juveniles: 59% animal and 41% plant; matures: 28% animal, 72% plant), but no significant differences were found between sexes. Aquatic arthropods and then seeds, fruits, and freshwater snails were the main items in the diet in juvenile turtles. In mature turtles, the most common items were fig fruits, seeds, nuts, and freshwater snails. This study suggests that *E. madagascariensis* at this site were more carnivorous in the smaller class sizes (<125 mm PL), shifted to opportunistic, omnivorous feeding habits as they got larger (125–200 mm

PL), and finally become opportunistic herbivores as adults (>200 mm PL), although they did continue to opportunistically take animal prey.

During the study period three fecal samples from juvenile *E. madagascariensis* revealed remains of the scorpion *Grosphus hirtus* Kraepelin (Lourenço and Goodman 2006. Zool. Anz. 244:181–185). The first sample was from a juvenile #215 (105 mm PL) caught at Antsilomba Lake (16°16'25.2"S, 46°43'04.3"E) on 22 February 1999. The second sample came from juvenile #585 (160 mm PL) on 3 March 2000 from the locality of Ambarindahy (16°15'11.7"S, 046°43'21. 8"E), and the third sample was collected from juvenile #711 (75 mm PL) at Lake Antsilomba on 13 March 2000.

This is the first record of turtles preying on scorpions in Madagascar, and possibly the first record of turtles eating scorpions anywhere (McCormick and Polis 1990. *In* The Biology of Scorpions, pp. 294–320. Stanford, Stanford Univ. Press).

GOPHERUS POLYPHEMUS (Gopher Tortoise). **MORTALITY**. *Gopherus polyphemus* has declined precipitously in range and numbers in Florida and recently was state-listed as a "threatened" species under the Florida Wildlife Code (Chap. 39, Florida Administrative Code). At ca. 1000 h on 27 July 2006, GK observed a 23 cm carapace length male *G. polyphemus* between the North-South railroad tracks on the eastern boundary of Savannas Preserve State Park (SPSP) in St. Lucie County, Florida (Fig. 1). The tortoise seemed uninjured, but was deceased. Eastern Box Turtles (*Terrapene carolina*) were recently shown to have great difficulty escaping railroad tracks, with overheating to critical levels likely to occur in 4.5–5 h (Kornilev et al. 2006. Herpetol. Rev. 37:145–148). Similarly, the most logical explanation for the Gopher Tortoise death would be entrapment between the tracks, followed by critical overheating and/or dehydration (high and average temperatures for the previous day had been ca 31°C and 28°C, respectively). Recent re-contouring of the railroad track right-of-way corridor with crushed rock had coincidentally created "ramps" (Fig. 2) increasing the feasibility for tortoises to scale the track rail to reach the interior portion of the tracks. Alternatively, access to the interior of the tracks could have been accomplished at the crossing intersection at nearby Walton Road, 186 m south of where the carcass was found, with the tortoise continuing to move along the tracks, instead of escaping by retracing its route. Turtle species with superior climbing abilities to *G. polyphemus* might be more able to escape entrapment between the 19 cm high rails (if they are of sufficient size). For example, Engeman (*in press*, J. Kansas Herpetol.) observed a 33 cm carapace-length *Apalone spinifera* climb a series of 14 stairs, each 18–19 cm high, indicating that such an individual might be able to escape the railroad tracks.

FIG. 2. View of tracks showing re-contouring of right-of-way with crushed rock, possibly allowing easier access to the interior of the tracks by *G. polyphemus.* Photo by G. Kaufmann.

Tortoises are subject to a variety of anthropogenic sources of mortality, with collisions with vehicles the most apparent for *G. polyphemus* in southeastern Florida State Parks (HTS, pers. obs.). Vehicles have likewise been well-documented as hazards for the related *G. berlandieri* (Engeman et al. 2004. Herpetol. Rev. 35:54–55), and *G. agassizii* (e.g., Boarman and Sazaki 1996. *In* Evink et al. [eds.], Trends in Addressing Transportation Related Wildlife Mortality, pp. 179–184. State of Florida Dept. Transportation, Tallahassee, Florida; Luckenbach 1982. *In* Bury [ed.], North American Tortoises: Conservation and Ecology, pp. 1–38. USFWS Wildl. Res. Rpt. 12). Additional causes of anthropogenic mortality for *Gopherus* spp. have included entanglement in wire fences (Engeman et al. 2004, *op. cit*.), although we have not detected this for *G. polyphemus* during fenceline searches in nearby Jonathan Dickinson State Park. Similarly, numerous patrols down the SPSP track corridor since Jan 2004 have not identified railroad related tortoise mortality prior to this observation. Therefore, we speculate that the re-contouring of the railroad track right-of-way may

have had made track entrance more likely for *G. polyphemus*.

HYDROMEDUSA TECTIFERA (South American Snake-necked Turtle). **COPULATION**. The freshwater chelid turtle *Hydromedusa tectifera* is distributed in rivers and streams of northeastern Argentina, Paraguay, eastern and southeastern Brazil, and part of Uruguay (Cei 1993. Mus. Reg. Sci. Nat. Torino Monogr. 14). The province of Córdoba (central Argentina) is home to a population that is isolated from the species' core distribution area and inhabits streams in the central region of the Sierras (Cabrera 1998. Las Tortugas Continentales de Sudamérica Austral. Privately printed, Córdoba, Argentina. 108 pp.). We report three observations of copulation of this species in two streams in Córdoba. In all observations, males were on top of females, grabbing them with the front and rear claws by the carapace edge, and continuously biting the central region of the neck. Males folded the tail to have it closer to the tail of the female. Copulation lasted less than 60 minutes on all three occasions. After copulation, the male released the female, which then swam rapidly away. The first copulation was observed at 2100 h on 11 October 2005 (spring) in Toro Muerto stream (31°23.5'S, 64°35.8'W). The specimens (carapace length 243 mm, male; 257 mm, female) were submerged at a depth of 40 cm, in a river section with sandy substrate, at a water temperature of 16.5°C and air temperature of 10°C. On 4 August 2006 (winter), we made a second observation, at 2015 h in Toro Muerto stream (31°22.7'S, 64°36.3'W). The specimens (carapace length 264.6 mm, male; 256.9 mm, female) were submerged at a depth of 30 cm, on a rocky, well vegetated substrate. Water temperature was 9°C and air temperature 3.5°C. The third observation was made in Tanti stream (31°21.2'S; 64°33.9'W) at 1920 h on 5 September 2006 (winter). The specimens (carapace length 240 mm, male; 251.2 mm, female) were submerged at a depth of 90 cm, on a rocky bed with sand and submerged aquatic vegetation. Water and air temperatures were 17°C and 20°C, respectively. *Hydromedusa tectifera* is one of the least documented reptile species in Argentina, especially concerning aspects of its ecology. This is apparently the first description of copulation of this species in the wild.

Submitted by **JULIÁN LESCANO**, **MARCELO BONINO**, and **GERARDO C. LEYNAUD**, Centro de Zoología Aplicada, Facultad de Ciencias Exactas, Físicas y Naturales, Universidad Nacional de Córdoba, Rondeau 798, CC 122, Córdoba (5000), Argentina (e-mail [GCL]: gleynaud@efn.uncor.edu).

KINOSTERNON SCORPIOIDES (Scorpion Mud Turtle). **BEHAVIOR.** Semiaquatic mud turtles (genus *Kinosternon*) are broadly distributed in a variety of habitats from eastern North America to northern Argentina. The southern two-thirds of this range is occupied by its largest member, *Kinosternon scorpioides*, of which various regional subspecies have been described based upon head and plastron coloration, extent of carination of the carapace, plastral seam ratios, and adult size (Ernst and Barbour 1989. Turtles of the World. Smithsonian Inst. Press, Washington DC. 313 pp.). The natural history of this species is not well known; its penchant for turbid shallow water, including anthropogenic habitats, outside of rain forests in northern South America is noted in the most exhaustive account of the species to date (Pritchard and Trebbau 1984. The Turtles of Venezuela. SSAR Contrib. Herpetol. No. 2, 403 pp. + 47 color plates + 16 maps).

On 11 November 1999 six specimens of *K. scorpioides* were found in a roadside pool and in a roadside ditch between Mariscal Estigarribia, Depto. Boquerón, and Parque Nacional Defensores del Chaco, Dept. Alto Paraguay, Paraguay. The GPS coordinates are 21°29'885"S, 59°52'736"W and 21°11'184"S, 59°45'188"W. The first individual was seen from a moving vehicle as it sat motionless, possibly basking, on the far embankment of the pool at 1115 h. Seconds later, upon my approach, the turtle moved quickly upwards, away from the water, towards the dense, spiny vegetation locally known as "chañar" consisting of various species of *Bromelia*, *Dyckia*, and *Aechmea*. More than 2 h later, in a roadside ditch stretching to the horizon, movement seen from the vehicle prompted investigation. Within 2 minutes, three searchers found 5 *K. scorpioides* (2 males, 2 females, 1 juvenile) in water no deeper than 30 cm. As they were pursued, two of the turtles emerged from the water body, climbed the embankment, and moved towards the adjacent chañar. The larger male and one female bore several ticks in the soft parts of their anterior portions, whereas the juvenile's carapace had a dense growth of algae.

There appear to be few literature records of aquatic turtles (i.e., those known to largely live and feed in aquatic habitats) purposely seeking immediate refuge away from the water. In this case, the spiny vegetation may have offered better protection from predators than did the open, shallow water.

Terrestrial refugia are apparently used by non-estivating aquatic chelonians elswhere in the Gran Chaco, in most of which there is no permanent surface water. In January 1987 and 1988, 7 of 26 specimens of *Acanthochelys pallidipectoris* were found beneath broad leaves of living bromeliads on dry land during the rainy season in nearby northern Argentina, in the vicinity of abundant, seasonal shallow bodies of water (Monguillot and Fabius 1993. Bol. Soc. Zool. Uruguay 2nda época 8:196–203). The seeking of terrestrial refugia (rather than nearer aquatic habitat) upon release by the third species of non-terrestrial chelonian in the region, *A. macrocephala,* following capture in shallow water has been recently documented by Métrailler (2006. Manouria 9[33]:26–32). This observation took place in February 2002.

LEPIDOCHELYS KEMPII (Kemp's Ridley Seaturtle). **DEVELOPMENTAL HABITAT**. Kemp's Ridley Seaturtle is unique because it nests primarily on a single beach in Tamaulipas, Mexico (Rancho Nuevo), and it nests during the day in large groups called

arribadas. Unfortunately, the population was severely reduced by the 1960s from intense egg harvesting and further reduced by the 1980s because of incidental capture in commercial fishing gear (Márquez-M. et al. 2005. Chelon. Conserv. Biol. 4[4]:761–766).

Studies describing the coastal developmental habitats of hatchling and juvenile Kemp's Ridley Seaturtles are important to scientists, conservationists, and resource managers for drafting sound recovery plans. A newly discovered developmental habitat has recently been described in Gullivan Bay, Ten Thousand Islands, southwestern Florida, USA (Witzell and Schmid 2004. Gulf Mexico Sci. 22:54–61; see also Schmid and Barichivich 2005. Chelon. Conserv. Biol. 4[4]:828–834). This area is centered just north of the Everglades National Park boundary. After the original turtle research was completed in Gullivan Bay, a visual survey was conducted southwards through the Everglades Park because tagging data suggested that the Gullivan Bay turtles were possibly transient.

The survey was conducted from December 2003 to August 2004. Each survey consisted of five individual days and was conducted bimonthly from a 7.6-m flat-bottom commercial fishing vessel. Each day typically lasted from 0700 h to 1600 h with two persons in the vessel at all times looking for turtles. We moved southwards from the village of Goodland through Gullivan Bay into the Everglades National Park, stopping in likely places and waiting for Ridleys to surface to breathe. We stayed within 1 km of the shore and frequently stopped at passes between islands where ridleys often congregate and waited at least 4–6 h before moving southwards to a new location. It was impossible to synoptically survey the entire area because stormy weather conditions frequently dictated where we could safely go. All sightings were recorded using a portable global positioning system (GPS).

There were 92 immature Ridley, 24 Loggerhead (*Caretta caretta*), 2 Green (*Chelonia mydas*), and 2 unknown turtle sightings recorded. Because of the possibility of duplicate sightings, these figures do not represent an actual turtle census, but they do indicate that Ridleys are utilizing this entire coast as developmental habitat. Turtles were seen on each survey in sea surface temperatures ranging from 17.3°C in December to 31.1°C in August. The sightings extended from Gullivan Bay to Lostmans River, a distance of approximately 68.6 km (Fig. 1). We were not able to safely travel beyond this point in this particular vessel so we do not know if Ridleys inhabit the waters further south in the Park. Immature Kemp's Ridleys were sometimes seen in small groups of 2–3 individuals but never consistently in the same locations, and no particular area seemed to consistently be more productive than other areas. This indicates possible movement throughout the entire area as they feed. There were proportionately more sightings in the north because we traveled through this area more often as we moved southward from Gullivan Bay (Fig. 1).

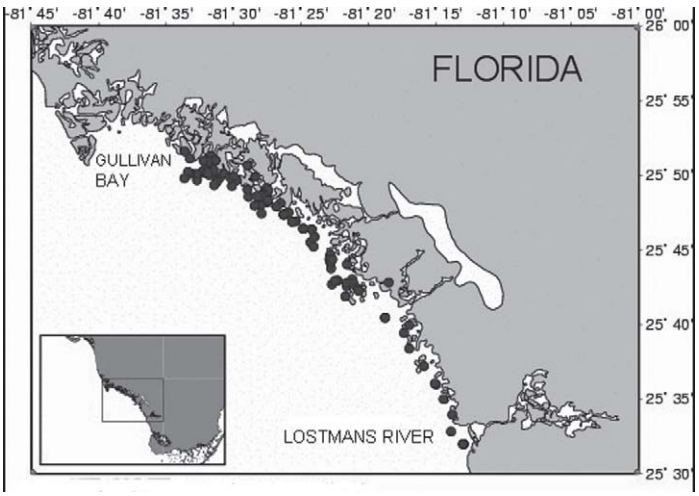

FIG. 1. Sightings of immature Kemp's Ridley Seaturtles from Gullivan Bay to Lostmans River, Ten Thousand Islands, Southwest Florida.

This stretch of Florida coast is the largest developmental habitat for immature Kemp's Ridley turtles discovered to date (76 km including Gullivan Bay). This habitat remained hidden until now because the area is remote and because there is little opportunity for turtles to be impacted by human activities (e.g., commercial fishing or channel dredging). Additionally, the coastline is not conducive for turtle strandings to be found due to the dense mangrove habitat, so the presence of these turtles remained unknown to sea turtle researchers until now. The other developmental habitats reviewed by Witzell and Schmid (*op. cit.*) are all important for the continued expansion of the population but they are relatively insignificant in size and possibly importance compared to the potentially huge habitat of the Ten Thousand Islands along the southwestern tip of Florida. This area will become more important as the population continues to rebuild and it is critical that it remain as pristine and undisturbed as possible. Fortunately, this area is protected from commercial fishing and coastal development by the Everglades National Park and it is suggested that National Park personnel be involved in the Kemp's Ridley Recovery Team as they draft a new Recovery Plan.

I thank the many volunteers from the National Marine Fisheries Service Laboratory in Miami who participated in the survey, M. Finn for logistical support, and to SEATURTLE.ORG for providing the Maptool graphics program.

MACROCHELYS TEMMINCKII (Alligator Snapping Turtle). **TERRESTRIAL REFUGIUM.** With the exception of nesting, *Macrochelys temminckii* has rarely been reported leaving the water (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, D.C., 578 pp.; Ewert 1976. Herpetologica 32:150–156). The few reported occurrences have been described as basking attempts (Ewert 1976, *op. cit.*; Farr et al. 2005. Herpetol. Rev. 36:168; Shelby and Jensen 2002. Herpetol. Rev. 33:304). On 7 July 2006 at 1251 h in the East Fork of Cadron Creek, Arkansas (USA), a male *M. temminckii* (354 mm carapace length, 309 mm carapace width) was located out of the water. This turtle was part of an ongoing telemetry project and was located every 3–5 days prior to and after the aforementioned observation. Between 2 July (previous location) and 7 July 2006, the turtle left the water and entered an exposed beaver den within the bank of the stream. The opening to the burrow was located under a large maple tree (*Acer* sp.) and was ca. 200 mm from the water. The

TABLE 1. Air, stream, and burrow temperatures for a *Macrochelys temminckii* refugium. All values are mean ± SD. Statistical differences, determined by a Tukey test, are indicated by letters.

	Air Temperature (°C)	Stream Temperature (°C)	Burrow Temperature (°C)
Mean	26.3 ± 3.6 [A]	25.7 ± 0.7 [B]	21.8 ± 0.5 [C]
Maximum	40.7	26.7	22.8
Minimum	17.3	24.1	20.3

entrance to the burrow was 450 mm in width and 250 mm in height. The burrow depth and width was unknown, but the turtle was located ca. 3 m from the burrow entrance using a long pole. Within 300 mm of the entrance, the burrow angled upward at ca. 30°. Humidity was high enough within the burrow to cause droplets of water to form on overhanging roots and the substrate was slightly muddy. On first location of the turtle (7 July 2006), the burrow temperature was 4.5°C cooler than the stream temperature.

On 17 July 2006, the turtle was still within the burrow. At this time a temperature sensitive data logger was launched and placed within the burrow ca. 3 m from the burrow entrance, directly next to the turtle. In addition, a temperature sensitive data logger was launched and placed directly outside of the burrow to record air temperature and another was placed in the stream (1 m in depth and ca. 2 m from the burrow entrance).

Between 9 August and 15 August 2006, the turtle left the burrow. On 15 August 2006 the turtle was located in the water ca. 20 m from the burrow entrance. The turtle had remained in the burrow for 33–44 days. A summary of the data collected during this time are shown in Table 1.

It is believed that the turtle was using the burrow as a form of refuge from the unfavorable conditions within the stream (e.g., high temperatures, shallow waters, and open canopy). Riedle et al. (2006. Southwest. Nat. 51:35–40) also reported *M. temminckii* using beaver dens and lodges within the stream, but did not determine if these turtles were completely submerged within the water or were perhaps above water level. A female *M. temminckii* was also found to use a beaver den within the bank of the stream during this study, but it was believed that this turtle was below the water level at the reported time. This female remained in the burrow from 27 May 2006 to 17 July 2006. During this time, the same burrow was occupied twice by one other female.

STERNOTHERUS ODORATUS (Stinkpot). **MORPHOLOGY**. During amphibian surveys on 14 April 2005 at 2000 h, a kyphotic adult female Stinkpot (Fig. 1) was observed resting on the bottom of the north end of Manlove Lake in northern Fayette County, Indiana, USA, at a depth of ca. 50 cm. This was the only Stinkpot observed during three nights (ca. 6 h) of shallow-water surveys in April 2005. She was captured by hand, measured (maximum carapace length 93 mm, maximum carapace width 73 mm, maximum carapace height 60 mm, maximum plastron length 78 mm),

FIG. 1. Kyphotic adult female *Sternotherus odoratus* from Indiana.

euthanized by freezing, dissected for reproductive data (seven 14 mm preovulatory follicles plus eight 8–10 mm secondary follicles present, suggesting two potential clutches), preserved in fixative, and deposited in the Florida Museum of Natural History (UF 150163). This is the only kyphotic Stinkpot observed among approximately 1000 captures in Indiana (e.g., see Smith and Iverson 2002. Amer. Midl. Nat. 148:185–189). Kyphosis in *S. odoratus* has previously been reported by Hartweg (in Nixon and Smith 1949. Turtox News 27:28–29) but without any details. In addition, Saumure (2001. Chelon. Conserv. Biol. 4:159) reported a kyphotic adult male from Ontario, Canada in 1984. Osteopathologic study of this most recent specimen might shed light on the cause of this rare phenomenon in turtles (reviewed by Saumure 2001, *op. cit.*). This turtle was collected under a Scientific Research Permit issued by the Indiana Department of Natural Resources.

Submitted by **JOHN B. IVERSON**, Department of Biology, Earlham College, Richmond, Indiana 47374, USA; e-mail: johni@earlham.edu.

TERRAPENE CAROLINA (Eastern Box Turtle). **THREATS.** On 9 June 2005 at 1435 h an adult male *Terrapene carolina* was observed (TPC) consuming a red paintball. The turtle appeared to have broken the paintball open and was consuming the liquid paint inside. The specimen was held for two hours, during which time it appeared normally active. It was then released. The site of this observation was at a recreational paintball facility in a forested area of the coastal plain of southeastern Virginia. Further observations in the area revealed numerous unspent and spent paintballs of many colors including; orange, red, pale green, bright green, blue and purple. No other box turtles were observed in the area at this time.

Terrapene carolina is omnivorous, selecting a wide array of food items (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, DC). Braun and Brooks (1987. Amer. Midl. Nat. 117:312–318) observed that color of fruits eaten by box turtles varied widely and included red, yellow, blue,

purple, and black, essentially the same colors as paintballs. Items documented in the diet of *T. carolina* that might resemble a paintball include blackberries (*Rubus* sp.), mayapples (*Podophyllum peltatum*), blueberries (*Vaccinium* sp.), grapes (*Vitis* sp.), wild strawberries (*Fragaria virginiana*), and black cherries (*Prunus serotina*) (Mitchell 1994. The Reptiles of Virginia. Smithsonian Inst. Press., Washington, DC). In addition, Ernst et al. (1994 , *op. cit.*) note that they also consume plums, tomatoes, and ground cherries. These fruits are similar in size, texture, color, and/or shape, to a paintball.

The ingredients of paintballs vary according to manufacturer and may include polyethylene glycol, glycerol (glycerin), gelatin, sorbitol, dipropyleneglycol, mineral oil, dye, ground pig skin, and water (Donaldson 2003. Veterinary Medicine 98:995–997). There is little information on the potential effects of some of these ingredients on reptiles, but Donaldson (2003, *op. cit.*) reviewed cases of ingestion by dogs and noted vomiting, ataxia, diarrhea, tachycardia, blindness, seizures, and tremors, among other symptoms. In two cases the dogs were euthanized because their central nervous system signs did not respond to treatment. Therefore, it is possible that consumption of paintballs could be harmful to turtles and/or other reptiles and wildlife. This observation adds to the growing body of literature on reptiles negatively interacting with litter, recently reviewed by Walde et al. (2007. West. N. Am. Nat. 67:147–149). Although box turtles remain locally common in Virginia, many are lost each year to road mortality and collection as pets, and populations generally are in decline because of habitat destruction and fragmentation (Mitchell 1994, *op. cit.*).

TRACHEMYS DORBIGNI (Brazilian Slider). **DIET.** Juveniles of *Trachemys dorbigni* feed on insects and aquatic vegetation, while adults are predominately carnivores (Gallardo 1977. Reptiles de los Alrededores de Buenos Aires. EUDEBA/Lectores, Bs. As. 213 pp.; Gallardo 1982. Anales de Parques Nacionales 15:65–75) or opportunists (Cabrera 1998. Las Tortugas Continentales de Sudamerica. Edic. Indep., Córdoba. 108 pp.). An opportunist grazer generally feeds on the most available and abundant food resource (Holland 1985. Herpetol. Rev. 16:112–113). Here we report *Trachemys dorbigni* feeding on *Limnoperna fortunei* (Golden Mussel), a bivalve native to Southeast Asia and introduced in the Delta do Jacuí region (Rio Grande do Sul, Brazil), in the 1970s (Mansur et al. 2002 Rev. Bras. Zool. 20[1]:75–84). *Limnoperna fortunei* exhibits a fast life cycle, with rapid sexual maturation and the capability for rapid dispersal. Additionally, it displays gregarious behavior, apparently lacks natural predators in the region, and, as an invasive species, is considered a major cause of the loss of biological diversity where it has been introduced (Ziller 2006. *In* http://www.sobrade.com.br/textos/trabalhos.htm. acc. 200610-13). Golden Mussels can cause the extinction of native bivalve species, death of macrophytes by root suffocation, modification of the planktonic community, increase in fish fragility, and economic damage (e.g., clogging of pipes in urban water systems in the vicinity of the delta) (Neves et al. 1997. *In* Benz and Collins [eds.], Aquatic Fauna in Peril: The Southeastern Perspective, pp. 43–85. Southeast Aquatic Research Institut. Spec. Publ. 1, 554 pp.).

We observed the feeding habits of *T. dorbigni* from September 2004 to March 2005, while working on the Chelonia-RS Project (long-term research about biology and conservation of freshwater turtles in southern Brazil), in the State Park of Delta do Jacuí (29°53'–30°03'S, and 51°28'–51°13'W – Rio Grande do Sul State, Brazil). Observations occurred at fixed sites on the margin of a silt canal (Pintada Island) heavily impacted by human activities. To facilitate fecal analysis, eight turtles (4 males and 4 females) were captured in baited traps and placed individually in plastic buckets with clean water. These animals were kept in the buckets for a maximum of 24 h to allow collection of fresh feces and then returned to the capture site. Fecal matter was isolated by filtration, fixed in 70% alcohol, and separated and analyzed using a dissecting microscope.

Brazilian Sliders will feed on sessile mollusks attached to dock pilings, as well as on those attached to ship's hulls. To remove the prey from the substrate, a turtle places the anterior limbs on the mollusk mass, and stabilizes its position with the posterior limbs. At the same time, it engulfs a mollusk shell in its mouth and retracts its head inside the carapace, breaking the mollusk from its attachment point. This predation appeared to target the Golden Mussel, as the species was present in all samples. Fecal analyses supported the visual observation of predation on the Golden Mussel, and showed that the animals also feed on native gastropods (Family Hydrobiidae), *Trichodactylus* sp. (Crustacea), plant material (Poacea, Angiospermae), and also ingest sand and synthetic material (fish line).

These results demonstrate the importance of *Trachemys dorbigni* as a potential biological regulator of *Limnoperma fortunei*.

We thank Fundação O Boticário de Proteção à Natureza (FBPN), Instituto Gaúcho de Estudos Ambientais (INGA), and Secretaria Estadual do Meio Ambiente (SEMA) for financial and logistic support.

TRACHEMYS DORBIGNYI (Brazilian Slider). **HATCHLING OVERWINTERING**. Turtles have evolved diverse strategies to maximize the success of incubation and the survival of hatchlings. In some species, hatchlings may postpone emergence from the nest after hatching, at times overwintering below ground and emerging in spring. This habit is known for several species of emydid turtles, including species of *Trachemys* from the northern hemisphere (Aresco 2004. J. Herpetol. 38:249–256; Tucker and Paukstis 1999. J. Herpetol. 33:608–615). Here we report the first known occurrence of this behavior for *Trachemys dorbignyi*, the most southerly distributed species of the genus.

Sampling over 13 years in southern Brazil had demonstrated that *T. dorbignyi* nest between the months of October and January

(Spring and Summer) (Bager 2007. Herpetologica. In press), and have an incubation period of approximately 95 days. All nest monitoring to date suggested that hatchlings leave the nests soon after hatching.

A *T. dorbignyi* nest was found opportunistically on 19 September 2006 (spring) when we were monitoring a nesting area in southern Rio Grande do Sul State - Brazil (UTM 22J x = 0370303mE; y = 6484280mN). The nest, constructed in argillo-arenaceous soil, had a narrow opening to the surface, presumably made by hatchlings which had left the nest previously. Four living hatchlings and egg shells, but no dead hatchlings or infertile eggs, were found. The hatchlings had lost the caruncle ("egg tooth"), and the abdominal yolk scar was totally closed, indicating a long post-hatching period. This observation was deemed an unusual instance of overwintering, as the majority of slider hatchlings in this area leave the nests immediately after total absorption of the residual yolk, still possessing a caruncle and with clear separation between the abdominal scutes at the yolk scar.

The hatchlings had an average maximum carapace length of 32.0 ± 2.2 mm (N = 4) and average 13.5 ± 0.6mm (N = 4) carapace height. These hatchlings were smaller than those measured in other localities in southern Brazil (average carapace length = 35.1 ± 1.3m; average carapace height = 16.8 ± 0.7mm [N = 77], unpubl. data).

Considering the latest nesting date known for the species in this region (10 January), hatching would usually occur by late April or early May (Autumn). In this area the lowest winter temperature does not reach the freezing point; average low temperature during July (coldest month) is 12.3°C (range 11–13.6°C). Considering that this species occurs in northern Argentina, where winter temperatures can fall below 0°C, future studies could determine if the hatchlings in the nest are tolerant of freezing temperatures.

FIG. 1. Top: Dorsal view of carapace depicting large yellow blotches on the first two pleural scutes and thick yellow ring around the marginal scutes. Bottom: Anterior view showing absence of dark green skin with black and yellow stripes replaced by yellow broken up by thin black stripes and narrow red bridge across the snout between the eyes.

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). **COLORATION**. A turtle captured alive in Lake Springfield in Springfield, Illinois, USA, on 21 August 2005, displayed an unusual color pattern morph. UTM coordinates are as follows using NAD27CONUS map datum in zone 16: N 0257716m, E 4429578m. The turtle is a female with the following physical measurements: carapace length = 166 mm, carapace width = 127 mm, carapace height = 63 mm, plastron length = 155 mm; total mass = 700 g. The turtle has an unusually high density of yellow pigment on the carapace, head, legs and tail. This is the only turtle discovered out of several thousand turtles captured to display these particular characteristics in our trapping in Illinois. Yellow pigment formed a thick ring around the outer carapace margin and formed dense blotches on the first two pleural scutes on both the right and left side with yellow comprising greater than half the area of the scute. In addition, the head, tail and legs lack the typical dark green with black and yellow stripes, which instead are all yellow separated by thin black stripes. The characteristic red patch is present behind the eye, along with a thin red stripe running horizontally across the snout. Similar color variations in wild *T. scripta* have been reported (Cagle 1947. Nat. Hist. Misc. 6:1–3; Tucker et al. 1995. Bull. Chicago Herpetol. Soc. 30[7]:148–149), as well as for *Chrysemys picta* (Harding 1982. Herpetol. Rev. 13:19).

The color pattern on this turtle is consistent with some of the so-called "pastel" color morph Red-eared Sliders which are commonly offered in the pet trade industry. Because Lake Springfield is highly accessible to the public and located within an urban area, it is plausible that a "pastel" Red-eared Slider was introduced here. However, because these pigmentation anomalies can occur under natural conditions, there is no way to be certain of this turtle's origin. The turtle was photographed, marked, and released.

Submitted by **JAMES T. LAMER** (e-mail: jthos50@hotmail.com), **CHAD R. DOLAN** (e-mail: chdolan@inhs.uiuc.edu), and **JOHN K. TUCKER** (e-mail: jktucker@inhs.uiuc.edu), Great Rivers Field Station, Illinois Natural History Survey, Brighton, Illinois 62012, USA.

TRACHEMYS SCRIPTA (Red-eared Slider Turtle). **PREDATION**. Predation on waterfowl and other birds by Common Snapping Turtles (*Chelydra serpentina*) is well known, but avian predation by other aquatic turtles is rarely reported (Pryor 1996. Wilson Bull. 108:190–192; Ernst et al. 1994. Turtles of the United States and Canada, Smithsonian Inst. Press, Washington, DC). Here I report an observation of predation of an adult passerine by aquatic emydid turtles.

At approximately 1400 h on 31 May 2002, an agonistic encounter was observed between two adult male Red-winged Blackbirds (*Agelaius phoeniceus*) on the surface of a small pond in Greer County, Oklahoma (USA). While viewing the dispute through field glasses, three adult Red-eared Sliders (*Trachemys scripta elegans*) were observed swimming toward the two birds. When the turtles got within approximately 3 m, one of the birds flew away. The second bird stayed on the surface of the water with wings spread and beak agape, apparently exhausted. A third male Red-winged Blackbird attacked the water-bound male, but retreated almost immediately, perhaps noticing the turtles nearby. After the second aggressor retreated, all three turtles disappeared beneath the water, and seconds later the remaining blackbird disappeared as well. An incomplete bird carcass floated back to the surface less than a minute after being pulled under water, and the turtles were not observed again.

With the exception of waterfowl, predation of adult birds by turtles is apparently an unusual and opportunistic event. The fact that three turtles were involved likely does not necessarily suggest cooperation, but is perhaps an indication of the high densities of Red-eared Sliders in this and other nearby ponds

I thank Joy Yoshioka and Wesley Webb for assistance in the field, and Oklahoma Department of Corrections for access to the ponds where the above observations were made.

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). **KYPHOSIS**. Turtle research at the Great Rivers Field Station of the Illinois Natural History Survey has resulted in the capture of more than 25,000 individual Red-eared Sliders (*Trachemys scripta elegans*) in west-central Illinois and neighboring Missouri. These turtles have included a number of specimens with unusual carapace morphologies that likely represent extremes in range of morphologies for turtle shells, including kyphotic individuals (Tucker 1997. Bull. Md. Herpetol. Soc. 33:171–177). Most kyphotic turtles have the highest point on the carapace located at vertebral scute two or three on the front half or middle of the carapace (e.g., Plymale et al. 1978. Southwest. Natur. 23:457–462; Rhodin et al. 1984. Brit. J. Herpetol. 6:369–373; Stuart 1996. Bull. Chicago Herpetol. Soc. 31:60–61), but see Fig. 1, an unusual four-year old male. Our large sample sizes allow a robust estimate of the frequency with which kyphosis occurs in this slider population.

Kyphosis in naturally occurring sliders is apparently rare. We found 14 turtles (0.06%) that we identified as kyphotic among 21,786 turtles captured in Calhoun and Jersey Counties in Illinois between 1994 and 2006. Males (N = 8) and females (N= 6) were equally likely to be kyphotic ($\chi^2 = 0.29$, 1df, $P = 0.5830$). Kyphosis seems to be uncommon in other turtles as well but the rate of occurrence varies considerably. Five of 929 (0.5%) Lancaster County, Pennsylvania Painted Turtles (*Chrysemys picta*, Ernst 1971. J. Herpetol. 5:216–220) were kyphotic. Stuart (*op. cit.*) found a single kyphotic Western Painted Turtle (*Chrysemys picta belli*) among 429 total captures (0.23% of sample). A single Spotted Turtle (*Clemmys guttata*, Ernst 1976. J. Herpetol. 10:25–33) among 207 (0.5%) examined was kyphotic. Spinal deformities occur in sea turtles at a low rate. Only 0.03% of more than 11,000 turtles of five species were kyphotic (Rhodin et al., *op. cit.*).

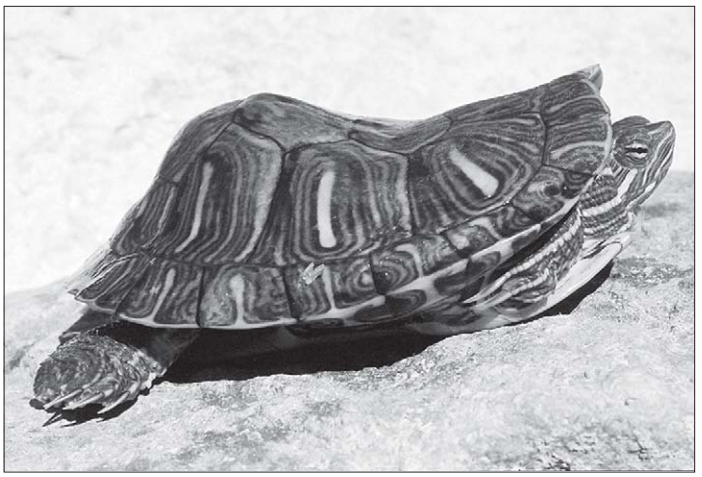

FIG. 1. An unusually shaped Red-eared Slider (*Trachemys scripta elegans*) juvenile male collected at Long Lake, Jersey County, west-central Illinois.

Despite the frequency with which kyphotic turtles have been reported in the literature, virtually nothing is known of the etiology of the condition. Various hypotheses have been advanced from problems with yolk retraction (Williams 1957. Herpetologica 13:236) to premature fusion of the shell (see Stuart, *op. cit.* and Saumure 2001. Chelonian Conserv. Biol. 4:159 for recent reviews). Only experimental manipulation will lead to an understanding of the basis for kyphosis. Such experiments will be difficult given the apparent rarity of the condition. It is, however, important to record the frequency of occurrence of kyphosis in various species of turtles because variation in rates of occurrence may shed light on the cause of the condition and the effect on individual turtles. Thus, the relatively high rate (2.6%) of kyphosis in a small sample of Common Musk Turtles (*Sternotherus odoratus*, Saumure, *op. cit.*) may be noteworthy or simply reflect the small sample studied (N = 39). The variation in rate of occurrence (0.03–2.6%) reported here further underscores the need for data on large samples from more species. It may be that smaller turtles (*C. picta, C. guttata*, and *S. odoratus*) are more likely to exhibit kyphosis than are larger turtles (*T. scripta* and sea turtles). Rate of occurrence among the small-bodied turtles is roughly 10 times that for larger-bodied species (0.23% to 2.6% versus 0.03% to 0.06%, respectively). Perhaps yolk retraction is more difficult among smaller turtle hatchlings or errors in shell development have more profound effects in small turtles. Any hypothesis, however, is premature until more species are studied.

CROCODYLIA

CROCODYLUS INTERMEDIUS (Orinoco Crocodile). **JUVENILE FEEDING.** *Crocodylus intermedius* is one of the most critically endangered crocodilians (Rodríguez and Rojas 2003. Libro Rojo de la Fauna Venezolana, IUCN. 2nd. ed, Fundación Polar/PROVITA, Caracas. 472 pp.). It occurs in the Orinoco River Basin in Venezuela, and has been the focus of captive breeding and habitat protection policies (Thorbjarnarson 1988. Proc. World Conf. Breeding Endangered Species Captivity 5:307–314). Few data exist on the feeding behavior of juvenile crocodiles (*Crocodylus acutus* [Thorbjarnarson 1989. *In* Hall (ed.), Crocodiles: Their Ecology, Management and Conservation, pp. 228–258. A Special Publication of the Crocodile Specialist Group IUCN/SSC. Gland, Switzerland]; *C. johnstoni* [Webb et al. 1982. Aust. J. Zool. 30:877–899]; *C. niloticus* [Games 1990. *In:*Proc. Ninth Working Meeting Crocodile Specialist Group. Vol. 1, pp. 251–267. IUCN. Gland, Switzerland]; *C. porosus* [Taylor 1979. Aust. Wildl. Res. 6:347–359; Davenport et al. 1990. J. Zool. Lond. 220:569–592]), but no published data exist on the feeding behavior of juvenile *C. intermedius*. Hence, here I report an observation of juvenile *C. intermedius* feeding.

I made the observation at Fundo Pecuario Masaguaral, a cattle ranch with a crocodile farm (Blohm 1982. *In* Proc. Fifth Working Meeting IUCN/SSC Crocodile Specialist Group, pp. 267–285. Gland, Switzerland) in State of Guárico in the Central Llanos of Venezuela (8°34'N, 67°35'W; elev. 60–75 m). The Central Llanos are lowlands (below 75 m elevation) with a well-defined wet season (May–Nov) dominated by open grasslands interspersed with deciduous forests (Troth 1979. *In* J. Eisenberg [ed.], Vertebrate Ecology in the Northern Neotropics, pp.17–30. Smithsonian Inst. Press, Washington, DC). At 2000 h (at night), I encountered a juvenile *C. intermedius* (ca. 2.5 months old, 38 cm total length) holding an adult dead male *Bufo granulosus* (ca. 4.5 cm SVL) with its jaws in a water-filled truck track ca. 9 cm deep on an unpaved road. The juvenile *C. intermedius* was in the water, with only its head above the surface, holding the dead toad with its jaws, which first I noticed when I captured the juvenile. The toad was flaccid, belly down, head inward, body axis almost parallel to the *C. intermedius*' jaws axis, with only the toad's hind legs being visible outside the crocodile's jaws. The juvenile *C. intermedius* discarded the toad following capture, presumably because it has been disturbed.

Bufo granulosus males usually call from the ground around puddles (Hoogmoed and Gorzula 1979. Zool. Mededelingen 54:183–216), so the male *Bufo* may have been vocalizing. The juvenile *C. intermedius* escaped from an enclosure two months before this observation was made but displayed no signs of injury or starvation, suggesting that it was feeding regularly on its own. The juvenile was subsequently returned to its enclosure.

SERPENTES

ALSOPHIS ANOMALUS (Hispaniolan Brown Racer). **MAXIMUM SIZE.** On 24 June 2006, at Fondo Paradí, Parque Nacional Jaragua, Pedernales Province, Dominican Republic, about 1.5 km from the main road to Pedernales (town) at 17°48'11.93"N, 71°26'49.47"W, the body of an *Alsophis anomalus* that had been killed by locals was found by Miguel Landestoy, Pedro Genaro Rodríguez, and Enrique Ureña. It had a total length of 2743 mm and a SVL of ca. 2000 mm, which exceeds by a substantial margin the maximum SVL (1770 mm) reported in Schwartz and Henderson (1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville. 720 pp.). This species is infrequently encountered despite a relatively extensive distribution on the western half of Hispaniola (Powell and Henderson 1998. Cat. Amer. Amphib. Rept. 659:1–2). Given that *A. anomalus* is the largest species in the genus, this specimen also constitutes a size record for the genus, for West Indian colubrids, and probably for any xenodontine colubrid (rivaled only by *Clelia clelia*). Total length of the specimen was

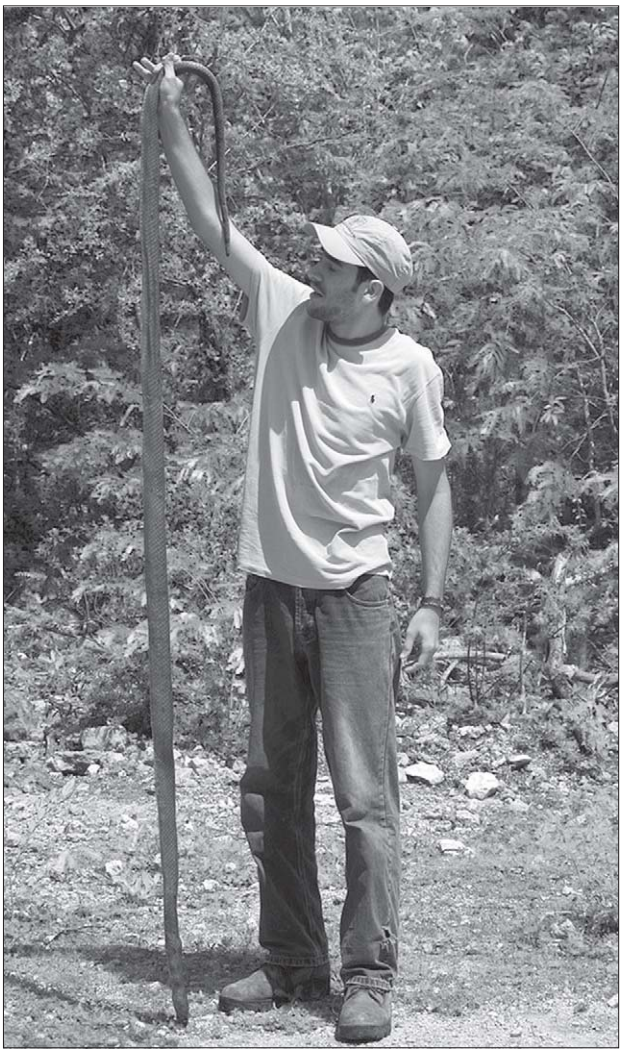

FIG. 1. *Alsophis anomalus* of record length. Miguel Landestoy, holding the snake, is 1855 mm (73 inches) tall. Photograph by Pedro Genaro Rodríguez.

measured in the field (Fig. 1). Although the specimen was easily identifiable, by the time it was recovered for preservation it could only be saved as a skeleton. It has been deposited in the University of Puerto Rico-Rio Piedras (UPRRP 6492).

We thank S. Blair Hedges, Jorge Brocca, Nicolas Corona, and Eladio Fernandez for facilitating recovery of the specimen.

HENDERSON**, Milwaukee Public Museum, Milwaukee, Wisconsin 53233-1478, USA; **ROBERT POWELL**, Department of Biology, Avila University, Kansas City, Missouri 64145-1698, USA; and **PEDRO GENARO RODRÍGUEZ**, Sociedad Ornitológica de la Hispaniola, Edificio Fundación Progressio, Avenida Máximo Gomez, Santo Domingo, República Dominicana.

BOTHROPS MATTOGROSSENSIS (Mato Grosso Lancehead). **PREDATION**. *Bothrops mattogrossensis* is a terrestrial, medium-sized pitviper that inhabits open areas adjacent to semidecidual forests in seasonally flooded open plains (Martins et al. 2002. *In* Schuett et al. [eds.], Biology of the Vipers, pp. 307–328. Eagle Mountain Publishing, Eagle Mountain, Utah). On 21 Oct 2005 at ca. 0805 h, we found an adult *B. mattogrossensis* (ca. 70 cm SVL) being attacked by a *Buteogallus urubitinga* (Great Black Hawk) in a grassy field in the Brazilian Pantanal (19°27'10.5"S, 56°35'27.3"W, elev. 107 m), Mato Grosso do Sul State. The hawk gripped the pitviper by the head and, upon our approach, flew away to semideciduous forest carrying the snake in its talons. Raptors are important predators on reptiles; however, Burrowing Owls are the only published predators of *Bothrops* species (Martins et al. 2003. Herpetol. Rev. 34:147–148; Valdujo and Nogueira 2000. Herpetol. Rev. 31:45). Moreover, snakes are uncommon prey for *B. urubitinga*, which prey primarily on frogs and lizards, but also consume birds (Lewis and Timm 1991. Ornitologia Tropical 2:37).

Submitted by **ROBSON W. ÁVILA**, Departamento de Ciências do Ambiente, Campus do Pantanal, Universidade Federal de Mato Grosso do Sul. Av. Rio Branco, 1270. Caixa Postal 252. CEP 79301-970. CAMPOS**, Programa de Pós Graduação em Ecologia e Conservação, Centro de Ciências Biológicas e da Saúde, Universidade Federal de Mato Grosso do Sul, CEP 79070-900, Campo Grande, MS, Brazil (e-mail: ana_ccampos@yahoo.com.br).

CONIOPHANES FISSIDENS (Brown Spotbelly). **REPRODUCTION.** *Coniophanes fissidens* is known from San Luis Potosí and Michoacán, Mexico through Central America to central Ecuador (Savage 2002. The Amphibian and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. The University of Chicago Press. 934 pp.). Zug et al. (1979. Smithsonian Cont. Zool. 300:1–20) and Solorzáno (2004. Snakes of Costa Rica. Distribution, Taxonomy and Natural History, Instituto Nacional de Biodiversidad [INBio], Costa Rica, 791 pp.) reported on reproduction of female *C. fissidens*. The purpose of this note is to present the first information on the testicular cycle of *C. fissidens* from a histological examination of museum specimens.

Twelve *C. fissidens* (mean SVL = 299 mm ± 35 SD, range = 225–339 mm) from Costa Rica and Mexico were examined from the herpetology collection of the Natural History Museum of Los Angeles County, (LACM), Los Angeles, California. Snakes were collected during 1959–1985. Specimens examined by province (Costa Rica) and state (Mexico) were: Costa Rica: Cartago (LACM 150451, 150456, 150459, 150460); Heredia (150455, 150458); Puntarenas (150452–150454, 150466); Mexico: Chiapas (38179, 114063). The left testis and a portion of the vas deferens were removed for histological examination. Tissues were embedded in paraffin and histological sections were cut at 5 µm. Sections were mounted on glass slides and stained with Harris' hematoxylin followed by eosin counterstain. Slides were examined to determine the stage of the testicular cycle.

The testes of all males were undergoing spermiogenesis (= sperm formation). The lumina of the seminiferous tubules were lined by spermatozoa or several rows of metamorphosing spermatids. Monthly samples of spermiogenic males were: January (1), February (1), March (1), April (2), June (1), July (1), September (1), October (2), December (2). The vasa deferentia contained sperm. The smallest reproductively active male measured 251 mm (LACM 150454) and was collected in March. While samples were not available from all months, the presence of males undergoing spermiogenesis from most of the year indicates an extended period of spermiogenesis.

Other snakes from Costa Rica also exhibited extended periods of sperm formation: *Dendrophidion vinitor* (Goldberg 2003. Trans. Illinois State Acad. Sci. 96:295–300); *Drymobius margaritiferus* (Goldberg 2003. Texas J. Sci. 55:195–200); *Ninia maculata* (Goldberg 2004. Texas J. Sci. 56:81–84); *Erythrolamprus bizona*, *E. mimus* (Goldberg 2004. Texas J. Sci. 56:171–174); *Micrurus nigrocinctus* (Goldberg 2004. Carib. J. Sci. 40:420–422); *Hydromorphus concolor* (Goldberg 2006. Bull Maryland Herpetol. Soc. 42:169–170); *Geophis godmani* (Goldberg 2007. Bull Chicago Herpetol. Soc. 42:7–8). *Coniophanes fissidens* should be added to this group. Subsequent examinations of the testicular cycles of additional snake species are needed to determine the prevalence of prolonged periods of spermiogenesis in Central American snakes.

I thank Christine Thacker (LACM) for permission to examine snakes. Specimens from Costa Rica are part of the CRE collection donated to LACM by Jay M. Savage in 1998.

CROTALUS CERASTES (Sidewinder). **ATTEMPTED FEEDING** and **MORTALITY**. The diet of *Crotalus cerastes* consists largely of lizards and rodents (Brown and Lillywhite 1992. *In* Campbell and Brodie, Jr. [eds.], Biology of the Pitvipers, pp. 279–308. Selva, Tyler, Texas; Funk 1965. Herpetologica 21:15–17). Antelope squirrels (*Ammospermophilus* sp.) are among the rodents that have been recorded as prey of *C. cerastes* (Funk, *op. cit.*). Moore (1978. Copeia 1978:439–442) suggested that only very large

C. cerastes were capable of feeding on White-tailed Antelope Squirrels (*A. leucurus*). Here, we document an instance of a *C. cerastes* attempting to ingest an *A. leucurus*, which resulted in the death of both animals.

On 2 April 2001, one of us (BC) found a pair of courting *C. cerastes* on the eastern edge of the Kelso Dunes in Mojave National Preserve, San Bernadino County, California, USA. The pair was captured and the female (567 mm SVL; 133 g) was implanted with a radio-transmitter, released, and tracked until 31 May 2001 (the end of the spring field season). During this period she moved an average of 4.8 m/day. On 28 August 2001 (the beginning of the autumn field season), the signal was again located. The snake was 157.4 m from her 31 May location and was below ground in a dune stabilized by Big Galleta Grass (*Pleuraphis rigida*). The signal remained stationary throughout the entire autumn and following spring field seasons. We excavated the dune on 21 May 2002 and discovered the mummified body of the snake with the remains of an *A. leucurus* in her mouth. The pair was lying on their backs in a burrow system about 20 cm from the nearest entrance. The head of the snake was twisted slightly to her left and her mouth held the antelope squirrel around the shoulder.

It is unclear exactly how the snake died, but it is possible that after engaging her teeth to begin feeding, she was constrained by the position of the squirrel in the burrow and was unable to either continue swallowing or release the prey item. In this scenario, the cause of death would either be starvation or suffocation. Alternatively, the burrow might have collapsed as a result of movements associated with feeding, resulting in suffocation. Both specimens are deposited in the Soda Springs Desert Studies Center, Zzyzx, California (*Crotalus cerastes*, SSDSC 59; *Ammospermophilus leucurus*, SSDSC 60).

We thank J. Patton, A. Brumbaugh, the Columbus Zoo, and Ohio State University for assistance.

ELAPHE GUTTATA EMORYI (Great Plains Ratsnake). **DIET.** *Elaphe guttata emoryi* eats a wide variety of prey including rodents, ground nesting birds, and occasionally lizards (Werler and Dixon 2000. Texas Snakes: Identification, Distribution, and Natural History, University of Texas Press, Austin, Texas. 437 pp.). On 7 October 2006 (1100–1130 h) we collected an adult male *E. g. emoryi* (154 mm SVL, 72 mm TL, 124 g) under green briar vines in a live oak motte at Camp Bowie National Guard Training Facility (31°35'44.6"N, 098°53'58.7"W, 429 m elev.), Brown County, Texas, USA. The snake had an adult female *Sceloporus olivaceus* (103 mm SVL, 153 mm TL, 44 g) in its stomach that was consumed headfirst. The lizard and snake are deposited in the Angelo State Natural History Collection (ASNHC 14192-93), Angelo State University, San Angelo, Texas.

MASTICOPHIS FLAGELLUM (Eastern Coachwhip). **REPRODUCTION**. The reproductive ecology of *Masticophis flagellum* in the northwestern Gulf Coastal Plain near the convergence of the borders of northeast Texas, southeast Oklahoma, southwest Arkansas, and northwest Louisiana is poorly understood. Two *M. flagellum* clutches from northern and central Arkansas contained 14 and 18 eggs (Trauth et al. 1994. Proc. Arkansas Acad. Sci. 48:196–209). Clutches from Oklahoma contained 7, 12, and 13 eggs, and were oviposited from early to mid-July (Carpenter 1958. Herpetologica 14:113–115). A single female (1160 mm SVL, 322 g) from Smith County, Texas laid a clutch of 11 eggs on 29 June 1988 (Ford et al. 1990. Texas J. Sci. 42:355–368). Eggs from that clutch were 4.47 (SD = 0.29) cm long, 2.33 (SD = 0.05) cm wide, and weighed 15.3 (SD = 9.61) g.

On 14 June 2006, a female *M. flagellum* (1154 mm SVL, 1484 mm TL, 465.2 g [mass taken prior to egg removal]) was recovered from a rubbish pile ca. 4 km from the Arkansas-Texas border along George Thomas Road (33.33098-N, 94.0852-W, elev. 129 m, Datum: NAD27) and ca. 0.75 km S of the junction of this road with Fricks Road in the Liberty Eylau region of Texarkana, Bowie County, Texas. The animal was placed in cool storage (2.5°C) until 15 June 2006 when it was removed for photography. After approximately 30 min at 30°C the animal was listless and its vent appeared dilated for oviposition. I placed the animal in a 40 L aquarium with a lid, water, and a terra cotta flower pot as a shelter. On 16 June 2006 at about 0830 h the specimen was found dead. Fourteen eggs were dissected from the abdominal cavity, weighed with an electronic balance, and measured using Vernier calipers. Mass of individual eggs (mean = 11.16 g, SE = 0.097) was not normally distributed (Anderson-Darling: $A^2 = 0.739$, $P = 0.041$), whereas length (mean = 37.88 mm, SE = 0.377; $A^2 = 0.213$, $P = 0.815$) and diameter (mean = 22.82 mm, SE = 0.213; $A^2 = 0.383$, $P = 0.347$) were normally distributed. Eggs had the following measurements based on their location in the oviduct: Cranial (N = 5): mean mass = 11.1 g (SE = 0.1), mean length = 36.5 mm (SE = 0.5), mean diameter = 22.9 mm (SE = 0.2); Middle (N = 5): mean mass = 11.3 g (SE = 0.22), mean length = 38.3 mm (SE = 0.5), mean diameter = 22.5 (SE = 0.2); Caudal (N = 4): mean mass = 11.1 g (SE = 0.2), mean length = 37.2 (SE = 1.0), mean diameter = 23.2 (SE = 0.7). Although the absolute mean dimensions of eggs located centrally in the reproductive tract seemed larger, the position of the eggs in the reproductive tract was not a significant indicator of an egg's mass (Kruskal-Wallace: $H = 1.09$, $df = 2$, $P = 0.580$), length (ANOVA: $F = 0.71$, $df = 13$, $P = 0.501$), or diameter (ANOVA: $F = 0.730$, $df = 13$, $P = 0.504$).

The timing of reproduction by this female mirrors observations in northeast Arkansas and southeast Oklahoma (Carpenter, *op. cit.*; Trauth et al., *op. cit.*) and is only two weeks earlier than observed in Smith County, Texas (Ford et al., *op. cit.*). The clutch size in this observation is identical to the observation from Smith County,

Texas, comparable to the observations from southeast Oklahoma, and smaller than that observed in northeast Arkansas. Mean egg mass in this clutch is nearly 4 g lighter than observed in Smith County, Texas, despite the fact that our female is only 6 mm smaller. After data collection, the eggs were held at ambient temperature and misted daily until signs of mold appeared accompanied by a foul odor (18 June 2006). At this time the eggs were fixed in 10% formalin and deposited in a private (MLM) teaching-research collection. This observation fills a geographical void in our knowledge of the reproductive biology of *M. flagellum* in this region.

Submitted by **MALCOLM L. McCALLUM** (e-mail: malcolm.mccallum@tamut.edu) and **JAMIE L. McCALLUM**, Biological Sciences Program, Texas A&M University-Texarkana, 2600 Robison Road, Texarkana, Texas 75501, USA.

MASTICOPHIS SCHOTTI SCHOTTI (Schott's Whipsnake). **DIET.** Although documentation of the feeding habits of *Masticophis schotti schotti* is lacking (Werler and Dixon 2000. Texas Snakes: Identification, Distribution, and Natural History. University of Texas Press, Austin, Texas. 437 pp.), its diet is assumed to be similar to that of other *Masticophis*, which prey chiefly on lizards and birds. At 1730 h on 28 October 2006, I collected a DOR adult female *M. s. schotti* (945 mm SVL, 425 mm TL, 162 g) 1.1 mi N of the intersection of Texas Hwy 16 and Farm Road 2295 on Hwy 16 (27.59304°N, 098.65605°W, 193 m elev.) in Duval County, Texas, USA. The snake had an adult male (TD = 15 × 6 mm) *Peromyscus leucopus* in its stomach that was consumed headfirst. The mouse's measurements were: total length 178 mm, tail length 80 mm, hind foot 18 mm, ear 15 mm, and it weighed 23 g. The snake (ASNHC 14197) and mouse (ASNHC 13039) are deposited in the Angelo State Natural History Collection, Angelo State University, San Angelo, Texas.

MEHELYA NYASSAE (Black File Snake). **FEEDING.** On the evening of 23 February 2006 a female *Mehelya nyassae* (450 mm SVL, 44 mm tail length, 30 g) was discovered swallowing an *Acontias plumbeus* (Giant Legless Skink; 252 mm SVL, 44 mm tail length, 34 g) on the road in Mtunzini, South Africa. The two animals had been recently hit by a vehicle and both were dead. The anterior 150 mm of the skink had been swallowed by the snake before the snake had been hit by the vehicle and thus it is unclear whether the snake would have completely ingested the prey. Shine et al. (1996. J. Zool. London 240:327–340) indicate that the diet of *M. nyassae* consists largely of scincid lizards, but did not record any members of the subfamily Acontinae in the diet of this species. Shine et al. (*op. cit.*) also report the mean prey mass to predator mass ratio as being 0.15 with a maximum ratio of 0.45. Assuming that this snake would have completely ingested the prey item, this feeding record would represent a prey mass to predator mass ratio of 1.14, well exceeding the reported range.

NOTECHIS SCUTATUS (Australian Tiger Snake). **CANNIBALISM.** Incidental cannibalism in young snakes is frequently observed in captivity in a wide range of species, and usually occurs while the animals are being fed in a communal space. High frequency of cannibalism has been previously reported in *Notechis scutatus* from island populations during feeding events (Worrel 1963. Reptiles of Australia. Angus and Robertson, Sydney. pp. 132). Cannibalism between young *N. scutatus* was also recorded in the absence of food (Firmage and Shine 1996. Amphibia-Reptilia 17:55–65).

In March 2006, four pregnant female *N. scutatus* were captured on Williams Island, South Australia (35°01'54"S, 135°58'28"E) and two pregnant females were captured at Herdsman Lake, Western Australia (31°55'16"S, 115°48'17"E). In April 2006, 79 *N. scutatus* were born in captivity to these six females. Island neonates (22.8 ± 1.9 cm SVL, 8.9 ± 1.5 g; N = 50) and mainland neonates (17.8 ± 0.7 cm SVL, 4.4 ± 0.3 g; N = 29) significantly differed in snout–vent length ($F_{1,77}$ = 183.4; P < 0.01) and in body mass ($F_{1,77}$ = 256.4, P < 0.01) at birth. All snakes were housed individually under standardized conditions and fed dead mice every two weeks.

In the course of conducting other experiments, the now two-month-old snakes (body mass ranging from 4–11 g) were kept in groups of 3–16 individuals in small plastic boxes for three days. Cannibalism was observed on seven occasions, always in the absence of food stimuli and several days from the last feeding event. Victims ranged from 41% lighter up to 25% heavier, and from 17% shorter up to 11% longer than their attackers. Island snakes (Williams Island, South Australia) as well as mainland snakes (Herdsman Lake, Western Australia) displayed cannibalism. Island snakes preyed upon island snakes (2 occurrences) as well as mainland snakes (3 occurrences), while mainland snakes only consumed mainland snakes (2 occurrences), possibly reflecting the much larger size (and presumably strength) of island juveniles compare to their mainland counterparts (see above). Biting and other fighting behaviors were often observed, once involving two snakes biting a third individual. In most instances, snakes were separated by hand before cannibalism could occur. No bitten snakes seemed to suffer in an observable way from the effect of their attacker's venom. This report indicates that island and as well as mainland young *N. scutatus* are capable of cannibalism in captivity. There is no evidence that cannibalism occurs in the wild in this species. However it seems likely that some Island Tiger Snakes would display such behavior, especially in the absence of small prey items such as frogs (*Crinia*) and skinks (*Ctenotus*) that are the staple diet of mainland neonates (Aubret et al. 2004. Amphibia-Reptilia 25:9–17).

PSAMMOPHIS LEIGHTONI TRINASALIS (Fork-marked Sand Snake) and ***PSAMMOPHIS NOTOSTICTUS*** (Karoo Sand Racer). **ENDOPARASITES.** *Psammophis leightoni trinasalis*

occurs in eastern Namibia, Botswana, and northern South Africa; *P. notostictus* occurs in the Cape provinces and Southern Free State, South Africa through Namibia to southern Angola (Branch 1988. Field Guide to Snakes and other Reptiles of Southern Africa. Ralph Curtis Books, Sanibel Island, Florida. 399 pp.). To our knowledge, there are no reports of helminths from these snakes. The purpose of this note is to establish the initial helminth lists for *P. leightoni* and *P. notostictus*.

Twenty *P. leightoni trinasalis* from southern Africa (SVL = 431 mm ± 151 SD, range: 165–637 mm) and 4 *P. notostictus* (SVL = 453 mm ± 39 SD) deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California were examined: (*P. leightoni trinasalis* LACM 77106, 77107, 77463, 77660, 77661, 84178–84188, 84190–84193; *P. notostictus* LACM 77657–77659, 127500). A mid-ventral incision was made in the posterior third of the body and the coelomic cavity was searched for helminths. Nematodes were cleared in lactophenol and identifed from wet-mounts. Cestodes were stained in Delafield's hematoxylin, mounted in Canada balsam, coverslipped and identified from whole-mounts. Two species of Cestoda were found in *P. leightoni trinasalis*: *Oochoristica truncata* in LACM 77106 (prevalence, % infected/sample = 5%; mean intensity, mean number helminths per infected individual = 1.0) and *Mesocestodes* sp. in LACM 77660, 84181 (prevalence = 10%, mean intensity = 11.5 ± 0.72, range = 11–12), and one species of Nematoda, *Polydelphis anoura* in LACM 84180, 84181, 84185, 84187 (prevalence = 20%, mean intensity = 2.5 ± 2.4 SD, range = 1–6). One species of Cestoda was found in *P. notostictus*, *Mesocestoides* sp. in LACM 77657, 77659 (prevalence = 50%, mean intensity = 67.0 ± 11.3, range = 59–75). Helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as *P. leightoni trinasalis*: *Oochoristica truncata* (USNPC 99514), *Mesocestoides* sp. (USNPC 99515), *Polydelphis anoura* (USNPC 99516); *P. notostictus*; *Mesocestoides* sp. (USNPC 99513).

Oochoristica truncata is widespread in reptiles from southern Africa and has been reported from agamid, chameleonid, gekkonid, and scincid lizards, as well as boid and colubrid snakes (Goldberg and Bursey 2004. Afr. Zool. 39:111–114). *Psammophis* presumably becomes infected by ingesting prey harboring larvae of *O. truncata*. *Mesocestoides* is a cosmopolitan genus with a unique larval form, the tetrathyridium, commonly found in reptiles, birds, and mammals, which is infective to the predatory definitive hosts (Schmidt 1985. Biology of the Acanthocephala. Cambridge University Press, Cambridge, U.K. 519 pp.). Reports of tetrathyridia of *Mesocestoides* sp. in amphibians and reptiles are summarized in Goldberg et al. 2004 (Comp. Parasitol. 71:49–60). *Polydelphis anoura* is a widespread nematode reported from snakes from both the New and Old World (Baker 1987. Occas. Pap. Biol. Univ. Newfoundland 11:1–327; Ernst and Ernst 2006. SSAR Herpetol. Circ. 34. 86 pp.). Snakes are presumably infected by ingesting rodents harboring larvae (Anderson 2000. Nematode Parasites of Vertebrates. Their Development and Transmission. CABI Publishing, Wallingford, Oxon, U.K. 650 pp.). *Psammophis leightoni trinasalis* represents a new host record for *Oochoristica truncata*, *Mesocestoides* sp., and *Polydelphis anoura*. *Mesocestoides* sp.; *Psammophis notostictus* represents a new host record for *Mesocestoides* sp.

We thank Christine Thacker (LACM) for permission to examine snakes.

PYTHON MOLURUS BIVITTATUS (Burmese Python). **CLUTCH SIZE**. *Python molurus bivittatus* is the largest of three subspecies of *P. molurus*, all of which are native to Southeast Asia. Through popularity in the exotic pet trade and subsequent release or escape of captive specimens, *P. m. bivittatus* has established a viable breeding population within Everglades National Park (ENP), Florida, USA. This is of particular concern from a management stand point, given that clutch sizes for *P. molurus* have been reported as high as 107 eggs (Wall 1921. Ophidia Taprobanica or Snakes of Ceylon. Government printer, Colombo. 66 pp.). In contrast, the two largest native snake species present in ENP, the Eastern Indigo Snake (*Drymarchon corais couperi*) and the Eastern Diamondback Rattlesnake (*Crotalus adamanteus*) have much smaller reproductive capability, producing an average of ca. 8–9 eggs (range = 5–12; Ernst and Barbour 1989. Snakes of Eastern North America. George Mason University Press, Fairfax, Virginia. 282 pp.) and 15.7 live young (range = 4–28; Timmerman 1989. Unpubl. master's thesis, Univ. of Florida, Gainesville. 81 pp.), respectively. However, most accounts for *P. molurus*, in particular *P. m. bivittatus*, have been from captive animals with information on reproduction in the wild scant. Here, we report the first account of clutch sizes of wild-caught female *P. m. bivittatus* from ENP.

Using egg, oviductal, and ovarian follicle counts from females (Everglades National Park, EVER-8888: overall accession no. for python project) recovered and examined between 5 March 2004 and 17 March 2006, we found mean clutch size of *P. m. bivittatus* within ENP to be 35.8 ± 3.4 (N = 8; range 19–46). Females ranged in size from 266–462 cm total length, with the two largest females 462 cm and 385 cm total length producing the largest clutch sizes of 46 eggs each (one of shelled eggs and the other oviductal). Four females for which data were available had a mean total egg mass to female body mass ratio before oviposition of 17.6 ± 4.1%. For most species of snakes, clutches can account for between 10–45% of a female's mass before oviposition or birth, with an average of 30% (Greene 1997. Snakes: The Evolution of Mystery in Nature. University of California Press, Berkeley. 351 pp.). Clutch sizes reported here agree with previous observations that suggest average clutch sizes for *P. molurus* generally range from 29–50 eggs (Cox et al. 1998. A Photographic Guide to Snakes and other Reptiles of Peninsular Malaysia, Singapore and Thailand. Ralph Curtis Books, Sanibel Isle, Florida. 144 pp.) with larger clutch sizes associated with larger females (Greene, *op. cit.*).

SIBON LONGIFRENIS (Drab Snaileater). **DIET**. *Sibon longifrenis* is a small, nocturnal, arboreal snake that is reported to be a terrestrial gastropod specialist (Solorzano 2004. Snakes of Costa Rica. Instituto Nacional de Biodiversidad, Santo Domingo de Heredia, Costa Rica. 791 pp.). Congeners, *S. argus* and *S. nebulatus*, have been reported to eat centrolenid and hylid frog eggs, respectively (Ryan and Lips 2004. Herpetol. Rev. 35:278). At 2100 h on 8 October 2005 we encountered an adult male *S. longifrenis* (383 mm SVL, 162 mm TL, 9.3 g) in the process of consuming an egg mass of *Cochranella albomaculata* at Gosner Stage 20 (Gosner 1960. Herpetologica 1960:183–190). The snake was located ca. 2.75 m up on a mossy vine overhanging Rio Maria (Panama Province, Panama). Within 10 minutes we located an additional adult male *S. longifrenis* (396 mm SVL, 173 mm TL, 9.0 g) moving among branches ca. 3.5 m above the stream. The second snake contained an obvious food bolus. We manually palpated the food item from the gut and identified it as an egg mass of *C. albomaculata* at Gosner Stage 10. Both snakes and their gut contents were collected and assigned field numbers (AHS F-1913 and F-1911).

At the time of the observation, *C. albomaculata* was going through a seasonal breeding event where we observed multiple amplectic pairs, as well as recently deposited egg masses. In addition to the *S. longifrenis* consuming eggs, we also located a juvenile female *Leptodeira septentrionalis* (282 mm SVL, 75 mm TL, 4.9 g) moving through vegetation above the stream that had eaten a *C. albomaculata* egg mass at Gosner Stage 10. The *Leptodeira* specimen was collected and deposited in the Museo de Vertebrados de la Universidad de Panama (MVUP-1874), and the *C. albomaculata* egg mass was deposited in the Southern Illinois University at Carbondale Museum (H-2636).

This is the first report of *S. longifrenis* feeding on egg masses. Our report provides further evidence that members of the genus *Sibon* are not strictly terrestrial mollusk and earthworm eaters (Kofron 1985. Copeia 1985:164–174), but rather "goo-eaters" as reported by Greene (1997. Snakes: The Evolution of Mystery in Nature. University of California Press. Berkeley. 351 pp.). Based on our observation and the two published observations (Ryan and Lips, *op. cit.*) of *Sibon* spp. eating egg masses, these snakes may opportunistically consume whatever egg masses are available at the time, since all observations were during breeding events of the species consumed. Egg masses might constitute a seasonally abundant, clumped food source for a genus that typically feeds on other prey types, e.g., mollusks and earthworms.

We thank R. Brenes, the National Science Foundation (DEB # 0234386 and 021385), the Smithsonian Tropical Research Institute, Parque Nacional Omar Torrijos, and Autoridad Nacional del Ambiente (permit number SE/A-27-05) for assistance, permission, and/or funding.

SISTRURUS CATENATUS (Eastern Massasauga). **REPRODUCTION**. Organisms must allocate available resources among the competing demands of maintenance, growth, and reproduction. Allocation among these demands often can be shifted in response to changing environmental conditions (Lourdais et al. 2003. J. Zool., Lond. 259:123–129). This observation coupled with observations of ova atresia and the apparent disappearance of embryos in captive, gravid females has lead researchers to postulate that resorption can offset the extreme costs of reproduction in female squamates (see Blackburn et al. 1998. J. Morphol. 235:97–108). However, no direct evidence substantiating this inference exists (Blackburn et al. 2003. J. Morphol. 256:219–234). The female squamate uterus is not morphologically capable of enzymatic degeneration, although degeneration of embryos situated outside of the uterus (ectopic embryos) may occur (Blackburn et al. 1998, *op. cit.*). Ectopic embryos are rare (constituting 2% of embryos in some snake populations), and typically are the result of either an injury sustained during a previous breeding season or a dysfunction at ovulation (Shine 1977. Aust. J. Zool. 25:655–666). Oocytes may occasionally migrate through the infundibulum into the peritoneal cavity where embryogenesis can still occur before degeneration (Shine 1977, *op. cit.*).

On 25 July 2002, we encountered a gravid female *Sistrurus catenatus* at Eldon Hazlet State Park, Clinton County, Illinois, USA. An ultrasound on 29 July 2002 at the Saint Louis Zoological Park by staff veterinarians revealed four seemingly viable embryos and one unfertilized oocyte. On 22 August 2002, the female birthed three offspring (two viable, one stillborn) and one unfertilized oocyte. The discrepancy in number prompted a postpartum ultrasound on 30 August 2002, which revealed one embryo was not passed. This embryo was not located in the reproductive tract, but rather, in the peritoneal cavity. Following veterinary recommendation, we monitored the female in captivity where she was provided food and water *ad libitum*. A follow-up ultrasound on 14 October 2002 revealed complete embryonic degeneration and a large amount of fluid in the peritoneal cavity. The female died in captivity from unknown causes approximately one month later. Complications resulting from embryonic degeneration can neither be substantiated nor ruled out.

Although the exact cause of this ectopic pregnancy and factors pertaining to the death of the female remain unknown, it is evident that ectopic embryos can reach full embryogenesis before degeneration. Though the morphology of the oviduct is incapable of resorption (Blackburn et al. 1998, *op. cit.*), it is unknown whether females are capable of resorption of ectopic embryos.

We thank the Illinois Department of Natural Resources, U.S. Army Corps of Engineers, St. Louis Zoo, and numerous volunteers for assistance.

THAMNOPHIS COUCHII (Sierra Gartersnake). **PREDATOR-PREY INTERACTION**. Recent studies have demonstrated that populations of the Common Gartersnake (*Thamnophis sirtalis*) have evolved variable amounts of resistance to tetrodotoxin (TTX), a powerful neurotoxin found within newts of the genus *Taricha* (Brodie and Brodie 1999. Bioscience 49:557–568). Production of TTX in the Rough-skinned Newt (*Taricha granulosa*) and associated resistance in *T. sirtalis* form the basis of a complex coevolutionary relationship between these two species (Brodie et al. 2002. Evolution 56:2067–2082). Within the range of *T. granulosa*, sympatric populations of *T. sirtalis* exhibit a wide spectrum of TTX-resistance that is present in some populations, and absent in others (Brodie et al. 2002, *op. cit*.). It remains unclear if, and to what extent, other species pairs of *Thamnophis*/*Taricha* exhibit TTX-mediated parallel co-evolutionary relationships. While conducting surveys along Cold Springs Creek in the Greenhorn Mountains (Tulare County, California) on 7 June 2000, C. R. Feldman and J. V. Vindum observed an adult *Thamnophis couchii* (CAS 212868) in the process of consuming a juvenile *Taricha torosa* (CAS 212869). This observation and subsequent lab studies demonstrate that TTX-resistance evolved independently in *T. couchii* (Brodie et al. 2005. J. Chem. Ecol. 31:343–356). Herein, we report an additional field observation of predation between these two species from another locality, over 300 km northwest of the Cold Springs Creek site.

On 8 October 2003 at 1257 h, while conducting amphibian surveys along the North Fork Mokelumne River, Calaveras County, California (38°27'39"N, 120°26'39"W; ca. 793 m elev.), ACP observed a subadult *T. couchii* (ca. 23 cm SVL) at the base of a sedge (*Carex* sp.) clump, in a shallow area. The snake had recently captured a juvenile *T. torosa* (ca. 3 cm SVL; Fig. 1). After ca. 5–6 minutes, the *T. couchii* had completely consumed the newt, tail-first. Following ingestion, the snake swam downstream and showed no outward behavior (e.g., paralysis or poor locomotor function) to indicate TTX poisoning from the ingested newt.

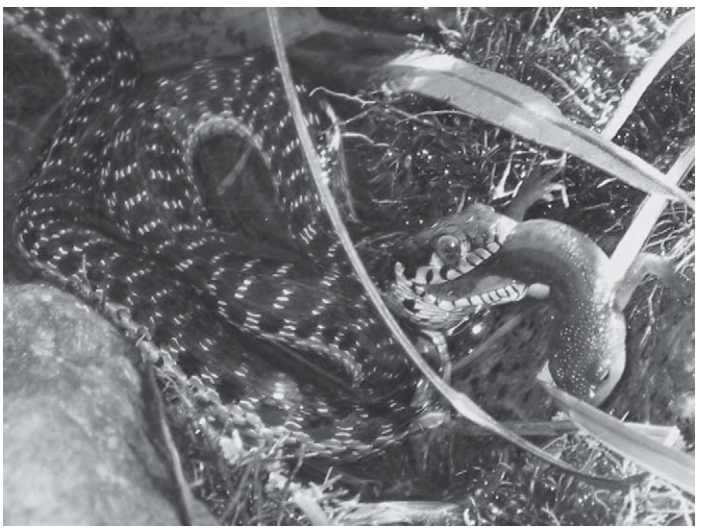

FIG. 1. A subadult Sierra Gartersnake (*Thamnophis couchii*) consuming a juvenile California Newt (*Taricha torosa*) from the North Fork Mokelumne River, California.

Newt prey from both field observations were juveniles, which typically have less TTX by surface area, than the average adult newt (Brodie et al. 2005, *op. cit.*). However, snakes from these observations differed in size: the *T. couchii* reported by Brodie et al. (2005, *op. cit.*) was an adult snake (48 cm SVL), while the snake reported here was a subadult (ca. 23 cm SVL). *Thamnophis sirtalis* are able to assess the toxicity of newts relative to their own resistance prior to ingestion, and symptoms of TTX-poisoning can occur as soon as one minute after prey capture (Williams et al. 2003. Herpetologica 59:155–163). We suspect that snakes from this locality may have elevated resistance to TTX, because the snake completely ingested the newt within an exposure time of at least 5–6 minutes (the newt was already captured upon initial observation), and because the snake swam away following ingestion. Alternatively, this population of *T. torosa* may exhibit uncharacteristically low levels of TTX, thus enabling *T. couchii* to consume them. The geographic structure of resistant/non-resistant populations within areas of sympatry of two coevolved species is believed to be an important component within such systems (Brodie et al. 2002, *op. cit.*). The geographic structure of the *Thamnophis sirtalis*/*Taricha granulosa* system resembles a mosaic of hotspots and coldspots within areas of sympatry and it seems possible that similar structure is present in the *Thamnophis couchii*/*Taricha torosa* system. The North Fork Mokelumne site is ca. 324 km northwest of the Cold Springs site within the Sierra Nevada of California and appears to be a resistant population. In a feeding ecology study of *T. couchii* from the North Fork Feather River (ca. 494 km northwest of the Cold Springs site), *T. torosa* was not identified in 102 prey items recovered from over 170 captured snakes (K. Wiseman, unpubl. data), even though both species are common locally and often encountered in the same microhabitats.

Fieldwork was conducted as part of Pacific Gas and Electric Company's Mokelumne River Project (FERC No. 137). We thank E. D. Brodie Jr., E. D. Brodie III, B. L. Williams, D. G. Mulcahy, C. R. Feldman, and P. Balfour for discussion and review of this note.

THAMNOPHIS COUCHII (Sierra Gartersnake). **PREDATION**. *Thamnophis couchii* is a highly aquatic species that inhabits streams, rivers, meadow ponds, and reservoirs of the Sierra Nevada of California from the Pit River drainage south to the western edge of the Tehachapi Mountains, with several populations east of the Sierran crest at Owens Valley, and along the Walker, Truckee, and Carson rivers in Nevada (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Univ. of Oklahoma Press, Norman. 332 pp.; Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin Co., New York. 533 pp.). Despite the fact that this species is frequently encountered within

its range, there are few reports detailing its ecological relationships with other species. To our knowledge the only documented predator of *T. couchii* is the Red-tailed Hawk (*Buteo jamaicensis*; Fitch 1949. Amer. Midl. Nat. 41:513–579). Herein, we report on two ophidian predators of *T. couchii* and discuss other likely predators.

On 10 June 2004 at 1615 h an adult *Coluber constrictor* (500 mm SVL; 630 mm TL) was captured ca. 5 m from the right bank of the North Fork Feather River near Shady Rest Area, Butte County, California (39°50'56.7"N, 121°23'38.6"W; 457 m elev.). The sluggish snake regurgitated a subadult *T. couchii* (330 mm TL; 10 g) which had been consumed head-first and was still alive following palpation. The snakes were released at the site (photos on file with KDW). The air temperature was 25.5°C (clear, sunny) and the water temperature was 16.5°C.

On 23 July 2004 at 1257 h a dead, adult *Diadophis punctatus* (422 mm SVL; 484 mm TL; CAS 231463) was found with a partially ingested subadult *T. couchii* (455 mm SVL; 549 mm TL; deposited with CAS 231463) at the same general locality as the *Coluber* observation (39°50'55.3"N, 121°23'38.2"W). The *D. punctatus* had ingested 65 mm of forebody of the *T. couchii* (11.8% of the gartersnake's TL) before it died (Fig. 1). The combined mass of both snakes was 22.8 g (preserved weight). The air temperature was 32.5°C (clear, sunny) and the water temperature was 22.0°C. The decomposed and dessicated snakes were found partially submerged in an edgewater along a lateral cobble bar. A small water release occurred on the morning of 23 July 2004 from above Cresta Dam, which likely inundated the snakes following death. Based on the level of decomposition, we estimate that the snakes died 2–3 days earlier.

Other likely, but as of yet undocumented predators of *T. couchii* include Great Blue Herons (*Ardea herodias*; Fitch, *op. cit*.; R. W. Hansen, pers. comm.; A. Lind, pers. comm.), Raccoons (*Procyon lotor*; Fitch *op. cit*.), and skunks (*Mephitis mephitis* and *Spilogale putorius*; Fitch, *op. cit*.). Introduced Signal Crayfish (*Pacifasticus leniusculus*) are also likely predators of *T. couchii* where the two species come into contact. On 24 June 2003 at 1910 h, during underwater video monitoring of *Rana boylii* egg masses on the North Fork Feather River, a signal crayfish was observed attacking (the crayfish crawled out beneath an egg mass and "pinched" the snake's tail with its cheliped) a subadult *T. couchii* that had briefly come to rest adjacent to an egg mass (our unpubl. data). Similar aggressive behavior was observed between a crayfish (species unknown) and *Thamnophis atratus hydrophilus* on 4 September 1986 at 1610 h at Hurdygurdy Creek in Del Norte County, California. A neonate *T. a. hydrophilus* (215 mm SVL; 284 mm TL; 5.0 g) was observed struggling in a shallow (9 cm deep) portion of the creek. When several rocks were moved around the struggling snake, a crayfish retreated from the snake's injured tail (A. Lind, pers. comm.). Although these aggressive behaviors do not demonstrate a predator/prey relationship, crayfish have been observed capturing and consuming other species of gartersnakes both in the field (*Orconectes virilis*/*Thamnophis elegans*; Weaver 2004. Herpetol. Rev. 35:278) and in controlled laboratory settings (*O. virilis*/*Thamnophis cyrtopsis*; Fernandez and Rosen 1996. Arizona Game and Fish Department, Heritage Fund IIPAM Project No. I94054, Phoenix, Arizona. 56 pp.).

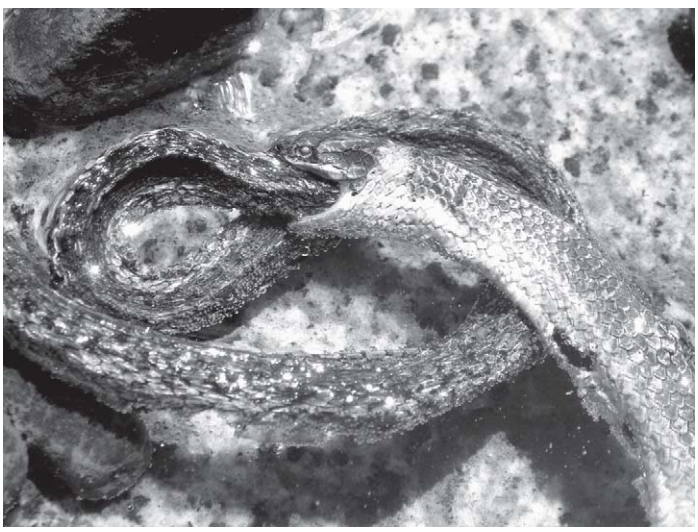

FIG. 1. An adult *Diadophis punctatus* (CAS 231463) which died while consuming a subadult *Thamnophis couchii*. The pair were found dead on 23 July 2004 on the North Fork Feather River, Butte County, California.

We thank R. W. Hansen, A. J. Lind, J. V. Vindum, and C. R. Feldman for their input. Field work was conducted in support of the Federal Energy Regulatory Commission's #1962 hydroelectric relicesening project.

THAMNOPHIS HAMMONDII (Two-striped Gartersnake). **FORAGING BEHAVIOR.** *Thamnophis hammondii* is considered one of the most aquatic of the gartersnakes and is closely associated with creeks and impoundments (Fitch 1940. Univ. California Publ. Zool. 44:1–150) with a diet consisting largely of both the larvae and transformed stages of amphibians (*Spea*, *Bufo*, *Rana*, *Pseudacris*) and small fish (*Oncorhynchus*, *Gasterosteus*, *Eucyclogobius*, and *Cottus*) (Jennings and Hayes 1994. Amphibian and Reptile Species of Special Concern in California. Final report contract no. 8023, California Department of Fish Game. 255 pp.; Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Univ. of Oklahoma Press, Norman. 332 pp.). Little is known regarding the foraging behavior of *T. hammondii* (Rossman et al., *op. cit*.). Herein, we describe the details of a predation sequence (approach, strike, and capture) observed in a natural setting.

On 13 March 1996 we observed an adult *T. hammondii* (ca. 45 cm SVL) preying on *Xenopus laevis* larvae (ca. 25 TL) in a seasonal cattle pond (ca. 50 m × 18 m, 0.75 m deep) in Dulzura, San Diego County, California, USA (32.62491°N, 116.77640°W, 475 m elev.). Except for several open areas maintained by a pair of swimming Mallards (*Anas platyrhnchos*), the majority of the pond's surface was covered by dense mats of well-established submergent vegetation (*Potamogeton illinoensis*, *Ranunculus aquatilis*). Centered in one of the open areas (ca. 0.5 m diameter) a school of *X.*

laevis larvae (N = 15–20) were observed about 10 cm below the surface. As nektonic filter-feeders, *X. laevis* larvae form essentially stationary schools near the surface of deeper water rather than hiding in the shallows (Wassersug and Hessler 1971. Anim. Behav. 19:386–389). An adult *T. hammondii* revealed its presence in the column of open water when it slowly protruded its rostrum above the water surface (duration not noted). Upon drawing its head down and slightly backwards in a slow and deliberate fashion, it formed (presumably resumed) an ambush position about 15 cm below the surface. With its tail anchored in stable aquatic vegetation, the greater part of its length was compressed into side by side loops from which the snake would periodically, quickly lunge (strike) forward. After each lunge the body was compressed again in preparation for the next lunge, sometimes remaining virtually motionless for ~2 minutes. Upon apprehending a *X. laevis* larva, the snake would retreat out of sight into the dense aquatic vegetation for ~1.5 minutes, and then reappear in the same place facing the same direction to resume its ambush position. This sequence of events continued for 25 minutes (N = 6 forward lunges: 2 successful captures, 4 misses) until observations ended.

The predation sequence of the snake does not fit into any of the foraging behavioral categories developed for *Thamnophis* snakes by Drummond (1983. Behaviour 86:1–30). The detailed Drummond study was the first to develop standard foraging behavioral categories for aquatic foraging snakes. In a subsequent study, Lind and Welsh (1994. Anim. Behav. 48:1261–1273), studying *T. atratus*, added two additional foraging categories to the Drummond scheme. We term the above reported underwater sit-and-wait predation sequence 'underwater ambush' and define it as: body completely submerged, tail anchored to a rigid object, strikes directly at prey. We propose that underwater ambush be considered an additional foraging mode for species of *Thamnophis*.

Additional reports of *Thamnophis* species foraging underwater while anchoring their tail have been made (*T. atratus*; Boundy cited in Rossman et al., *op. cit.*), although further details were not provided. In regard to *Thamnophis* species orienting their head towards prey and slowly compressing their body into a series of opposite loops in preparation of a forward strike, it has been reported in *T. couchii* during controlled underwater *ex situ* attack trials (Alfaro 2002. Funct. Ecol. 16:204–215).

Although other North American aquatic snake species (e.g., *Nerodia sipedon*) are known to anchor their tail to assist in underwater prey capture, they weave open jawed with a back and forth sweeping motion actively searching for prey, as opposed to the sit-and-wait strategy, as described above. Random searching with open mouth (open-mouthed searching, *sensu* Drummond 1983, *op. cit.*) is believed to be a strategy based on a combination of chemo and tactile senses (Drummond 1985. Anim. Behav. 33:206–215; Schaeffel and de Queiroz 1990. Copeia 1990:50–58), while forward-strike strategies (e.g., underwater ambush) are dependent on visual acuity (Alfaro, *op. cit.*; Drummond, *op. cit.*).

Additionally, single elements of the underwater ambush mode described above (e.g., anchoring of the tail, organizing the trunk into high amplitude loops, or lunging directly at prey with entire body underwater) have all been observed individually for *Thamnophis* by other investigators under controlled conditions (Alfaro 2002, *op. cit.*; Drummond 1983, *op. cit.*). Based on previous observations of single elements, and our observation of the combination of elements in a natural setting, it is likely that the underwater ambush strategy, reported here as a novel foraging behavior, is not an uncommon mode of foraging behavior for other aquatic specialist *Thamnophis* species while preying on nektonic prey (e.g., fish, *X. laevis* larvae) in the wild.

We thank A. Lind, H. Drummond, P. Medica, J. Funk, E. Camp, S. Mullin, and D. Wood for assistance.

THAMNOPHIS PROXIMUS (Western Ribbon Snake). **FORAGING BIOLOGY**. Although nocturnal foraging in or near ponds has been reported for *Thamnophis proximus*, Rossman et al. (1996.The Garter Snakes: Evolution and Ecology. University of Oklahoma Press, Norman, Oklahoma. 332 pp.) note the absence of scavenging behavior during road surveys in Texas and indicate that, although chemosensory cues are important for finding locations with prey, sight and motion play integral roles in the isolation of individual prey items by *Thamnophis*. On 21 May 2005, I drove a ca. 2.5 km section of Mecom-McCreit Road (near Hull, Liberty County, Texas, USA) between 2130 h and 2345 h. A thunderstorm had recently passed and during my survey light rains continued and air temperature measured 20.5°C. *Bufo valliceps* and *Hyla cinerea* were present on the road in an estimated density of several hundred per kilometer, many of which were DOR. During this time I observed seven adult *Thamnophis proximus* active on the road. Two were found attempting to ingest anurans. A female (621 mm SVL, 808 mm total length, 62.3 g) was collected at 2158 h near a portion of the road that was partially covered with water (30°10'03.5"N, 94°40'08.8"W). The snake was attempting to swallow a DOR *Bufo valliceps* (52 mm SVL, 18.1 g) breech. The toad's viscera were exposed and its skull crushed. The snake fled and continued to hold onto the toad even after capture. It was later released to the roadside near the point of collection. To the best of our knowledge, this represents the first observation of scavenging of road-killed anurans in this species.

TRIMORPHODON BISCUTATUS (Western Lyresnake). **DIET**. *Trimorphodon biscutatus* is a common species in the regenerating tropical dry forests of Guanacaste Province, Costa Rica. It is one of the most frequently encountered snakes in the secondary forests in and around the administration area of Sector Santa Rosa, Área de Conservación Guanacaste (10.84°N, 85.62°W, 295 m elev.), and often is observed crawling along the ground at night or foraging in scrubby vegetation 1–2 m above the ground. Although *T. biscutatus* has been described as primarily terrestrial (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna

Between Two Continents Between Two Seas. Univ. of Chicago Press., Chicago, Illinois. 934 pp.), it has been observed to climb trees when disturbed.

On the night of 7 October 2001, I watched a *T. biscutatus* consume a *Nyctidromus albicollis* (Common Pauraque; University of Kansas Digital Archive, KUDA 1863). Total length of the *T. biscutatus* was estimated at 130–140 cm from scaled photographs (not shown), while *N. albicollis* average ca. 22–28 cm total length and 55 g (Latta and Howell 1999. *In* Poole and Gill [eds.], The Birds of North America, No. 429, The Birds of North America, Inc., Philadelphia; Stiles and Skutch 1989. A Guide to the Birds of Costa Rica. Comstock Publishing Associates, Ithaca, New York. 656 pp.). The snake had swallowed ca. 25% of the *N. albicollis* at the time I encountered it, and the bird was no longer moving. From the body position of the snake, the bird appeared to have been constricted before swallowing. The snake took 45 more minutes to finish swallowing the bird.

Nyctidromus albicollis is a sit-and-wait predator that commonly sits on open ground (particularly road edges) waiting for insect prey to pass above it. I encountered the pair on a very low traffic road in a site known to be frequented by an individual *N. albicollis*. As the beginning of the encounter was not observed it is possible that the *N. albicollis* was killed by something else and scavenged by the snake, however it seems most likely that the bird was captured while foraging for insects.

TROPIDOPHIS MORENOI (NCN). **SIZE RECORD**. The previously reported measurements for *T. morenoi* (Hedges et al. 2001. J. Herpetol. 35:615–617) are 295 mm SVL and 45 mm tail length (holotype CZACC 4.5492; Colecciones Zoológicas del Instituto de Ecología y Sistemática, La Habana, Ciudad de La Habana province, Cuba; ex-collection IB 2493 from ex-Instituto de Biología, Cuba) and 285 mm SVL and 44 mm tail length (paratype CZACC 4.5493; ex-collection IB 2942). The type locality is Dolinas de Cueva de Humboldt, Caguanes, Villa Clara Province, Cuba (22°50'04"N, 80°12'02"W). This site now lies within Sancti Spíritus Province. An adult female of the genus *Tropidophis* (CZACC 4.12052) was collected by J. Salas (unknown date) from the same locality. It was identified by the senior author as *T. morenoi* on 20 January 2004 and is the first specimen of *T. morenoi* reported since the species description (Hedges et al., *op. cit.*). This specimen measures 359 mm SVL and 57 mm TL, exceeding the previous records by 64 mm SVL and 12 mm TL. Measurements of the head are not possible to determine because the head and neck are damaged. Coloration, scale counts, and measurements are the similar to those reported for the holotype and paratype.

We thank Elier Fonseca for suggestions on the manuscript.

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog). USA: GEORGIA: Chatham Co.: Savannah, house on Windward Island at 79 Rio Road (31.976°N, 81.186°W). 23 September 2004. Diane M. Butler. Verified by Kenneth Krysko. Florida Museum of Natural History, University of Florida (UF 142332). One adult female (111 mm SVL) was collected at the base of a sliding glass door in the backyard of the house. Cuban Treefrogs occur throughout much of Florida's peninsula (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publ. Co., Malabar, Florida. 155 pp.; Meshaka 1996. Herpetol. Rev. 27:37–40) and appear to be established as far north as Jacksonville on the Atlantic Coast (Krysko et al. 2005. Herpetol. Rev. 36:85–87), Cedar Key on the Gulf Coast (Johnson et al. 2003. Herpetol. Rev. 34:381), and Gainesville in the center of the peninsula (Krysko et al. 2005. Herpetol. Rev. 36:85–87). This is the first documented occurrence of a Cuban Treefrog in Georgia (J. Jensen, pers. comm.). The closest known record for the species is from Duval Co., Florida (Krysko et al. 2005. Herpetol. Rev. 36:85–87), approximately 180 km S of Savannah, Georgia.

Submitted by **STEVE A. JOHNSON**, Department of Wildlife Ecology and Conservation, University of Florida—IFAS Plant City Education Center, 1200 North Park Rd., Plant City, Florida 33563, USA; e-mail: tadpole@ufl.edu.

OTOPHRYNE PYBURNI. BRAZIL: AMAZONAS: Municipality of São Gabriel da Cachoeira, Parque Nacional do Pico da Neblina: Bebedouro velho (0°41'54"N; 65°55'41"W, 418 m elev.), 15 August 2005. Coleção de Anfíbios e Répteis, Instituto Nacional de Pesquisas da Amazônia, Manaus, Amazonas, Brazil (INPA-H 16473, SVL 46.8 mm; body mass in life 11 g). Bebedouro novo (0°45'21"N; 65°57'55"W, 847 m elev.), 17 August 2005 (INPA-H 16472, SVL 48.2 mm; body mass in life 11 g) and (INPA-H 16474 SVL 52.1 mm; body mass in life 13.5 g); 22 August 2005 (INPA-H 16475 SVL 20.1 mm; body mass in life 0.7 g). Three specimens were collected in dense closed canopy montane forest and one in dense closed canopy submontane forest near right bank of forest stream by V. T. Carvalho and L. Bonora and verified by R. de Fraga. This species occurs from Vaupés and Amazonas, Colombia, across the lowlands of southern Venezuela and through the Guianan region to Amapa, Brazil (Campbell and Clarke 1998. Herpetologica 54:301–317). In Venezuela this species was reported in Sierra Parima, 1100 m elevation (Barrio 1999. Herpetol. Rev. 30:173). Our record is 362 km and 358 km from these records reported in Sierra Parima. First state records, extends the known distribution 446 km and 440 km (airlane) east, respectively, from the type locality in the Vaupés, Wacará, SW Colombia (01°09'N, 69°55'W) (Campbell and Clarke, *op. cit.*).

Submitted by **VINICIUS T. DE CARVALHO** (e-mail: viniciustc@ig.com.br)**, LUCÉIA BONORA** and **RICHARD C. VOGT,** Instituto Nacional de Pesquisas da Amazônia – INPA, Coleção de Anfíbios e Répteis – Campus II. Av. André Araújo, 2936. C.P. 428. CEP 69.083-000 Manaus, Amazonas, Brazil.

PLEURODEMA MARMORATA (Andean Four-eyed Frog, Sapito de cuatro ojos andino). CHILE: TARAPACA: I Región, Quebe, ca. 180 Km NE of city of Iquique (19°27'18.0"S; 68°48'34.1"W), 3958 m elev.; 12 April 2007. M. A. Méndez, M. Sallaberry, and L. Pastenes. Herpetological Collection of Departamento de Biología Celular y Genética de la Universidad de Chile, Santiago, Chile (DBGUCH 0704038 juvenile). Lauca Sur (18°22'37.6"S; 69°20'49.0"W), 4232 m elev.; 14 April 2007. Same collectors. DBGUCH 0704058, adult. All verified by A. Veloso. Previously known from Caquena, Parinacota, Chungara, and Putre, XV Región (Cei 1962. Batracios de Chile. Ediciones de la Universidad de Chile, Santiago, Chile. cviii + 128 pp.; Veloso et al. 1981. *In* Veloso and Bustos [eds.], El Hombre y los Ecosistemas de Montaña I. La Vegetación y los Vertebrados Inferiores de los Pisos Altitudinales entre Arica y Lago Chungará, pp. 135–169). New record from Quebe extends southern range ca. 145 km S of Putre, the closest locality previously known (Cei 1962, *op. cit.*; Veloso and Navarro 1988. Boll. Mus. Reg. Sci. Nat. Torino 6:481–539).

The study was supported by the Grants PG-025-06 and MULT 05-04/2, University of Chile, and Fondecyt 1061256-2006.

HEMIDACTYLUS TURCICUS (Mediterranean House Gecko). USA: TEXAS: TRINITY CO.: 4218 FM 357, Kennard (31°15.570'N, 95°02.853'W). Collected on 18 July 2006. TCWC 91800. Verified by Toby Hibbitts. New county record (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M Univ. Press, College Station, Texas. 421 pp.). Specimen collected at a residence.

Submitted by **CORY K. ADAMS**, Southern Research Station, USDA Forest Service, Nacogdoches, Texas 75965, USA.

HETERODACTYLUS LUNDII. BRAZIL: BAHIA: Municipality of Mucugê, Caraíbas Farm (13°08'09"S, 41°24'15"W). 8 December 2005. 1100 m elev. M. A. de Freitas and T. F. Santos Silva. Museu de Zoologia da Universidade de São Paulo, São Paulo, Brazil (MZUSP 95588). Verified by A. J. Suzart Argôlo. Previously known only from the type locality in the southern portion of the Serra do Espinhaço, Minas Gerais state, Brazil (Bertoluci 1998. *In* Machado et al. [eds.], Livro Vermelho das Espécies Ameaçadas de Extinção de Minas Gerais, pp. 442–443. Fundação Editora Biodiversitas, Belo Horizonte, Brazil). First state record, extends known distribution ca. 700 km N from Serra da Piedade, Caeté, Minas Gerais, Brazil (Bertoluci 1998, *op. cit.*)

Submitted by **MARCO ANTÔNIO DE FREITAS,** Programa de Pós-graduação em Zoologia, UESC (Universidade Estadual de Santa Cruz) CEP 46.500-000 Rodovia Ilhéus/Itabuna, Ilhéus, Bahia, Brazil **(**e-mail: philodryas@hotmail.com**)**; **THAÍS FIGUEIREDO SANTOS SILVA**, Biogeographia publicações e consultoria ambiental, Rua E quadra D lote 11, Jardim Aeroporto, CEP 42700-000, Lauro de Freitas, Bahia, Brazil (e-mail: thaisfsilva@hotmail.com); and **MIGUEL TREFAUT RODRIGUES**, Instituto de Biociências, Museu de Zoologia da Universidade de São Paulo (USP) CEP 05586-060, São Paulo, SP, Brazil (e-mail: mturodri@usp.br).

LEIOCEPAHLUS CARINATUS (Northern Curly-tailed Lizard). USA: FLORIDA: MONROE CO.: Key West, 3700 Northside Drive (24°34'11.69"N, 81°45'25.398"W, Datum WGS84). 09 February 2006. Kim Gabel. UF 150934. Verified by Kevin M. Enge. New island record. Southernmost verified locality in the United States and extends known range of this species ca. 82 km S of previous southernmost record in Islamorada, Lower Matecumbe Key (Meshaka et al. 2006. J. Kansas Herpetol. 17:6). Big Pine Key, 263 Ship's Way (24°40'26.641"N, 81°22'5.941"W, Datum WGS84). 29 March and 04 May 2007. Jeanette Hobbs. UF 150933 and 151170, respectively. Verified by Kenneth L. Krysko. New island record and ca. 45 km NE of our Key West locality.

Submitted by **KENNETH L. KRYSKO**, Florida Museum of Natural History, Division of Herpetology, University of Florida, Gainesville, Florida 32611, USA; and **KIM GABEL**, UF/IFAS/ Monroe County Extension, 1100 Simonton Street, Suite 2-260, Key West, Florida, USA; and **JEANETTE HOBBS**, 263 Ship's Way, Big Pine Key, Florida 33043, USA.

LIOLAEMUS FITZINGERI. ARGENTINA: SANTA CRUZ: DEPARTAMENTO RIO CHICO: Ruta Nacional 40, 99.6 km N Tres Lagos, 3 km N Estancia La Siberia, dunes on east shore of Lago Cardiel (48°57'S; 71°01"W 399 m elev.) 16 January 2007. L. J. Avila, C. H. F. Perez, C. Zanotti, J. W. Sites, Jr. Museo de La Plata herpetological collection (MLP.S 2598); Luciano Javier Avila/ Mariana Morando-CENPAT Herpetological collection (LJAMM 7340, 7343). Verified by D. R. Perez. Previously known from southern Chubut and northern and eastern Santa Cruz provinces (Cei 1986. Reptiles del Centro, Centro-oeste y Sur de la Argentina. Herpetofauna de las Zonas Aridas y Semiaridas. Monograph 4. Museo Regionale di Scienze Naturalli Torino. 427 pp.). Southwesternmost record for the species and new department record, extends the known distribution 250 km S from nearest locality on southern coast of Lago Buenos Aires (Avila et al. 2006. Biol. J. Linn. Soc. 89[2]:241–275). This record is a notable geographic extension for the species in the area. Lago Cardiel sand dunes are apparently isolated from any other suitable habitat for *Liolaemus fitzingerii* and sampling efforts in other surrounding areas were unsuccessful, suggesting that this population is a remnant of a larger distribution in the past.

Submitted by **LUCIANO J. AVILA, CRISTIAN H. F. PEREZ, MARIANA MORANDO**, CENPAT-CONICET, Boulevard Almirante Brown 2825, U9120ACF, Puerto Madryn (Chubut), Argentina (e-mail: avila@cenpat.edu.ar); and **JACK W. LYGOSOMA BOWRINGII (Bowring's Supple Skink). BANGLADESH: COMILLA DISTRICT: Lalmai-Tipperah Hills (23°22'N, 91°07'E), 12 July 2006. S. Mahony and A.H.M. Ali Reza. Wildlife Laboratory, Department of Zoology, Jahangirnagar University, Savar, Dhaka (JU 0050). Photograph deposited at USDZ, Raffles Museum of Biodiversity Research, National University of Singapore (ZRC[IMG].2.1). Verified by Indraneil Das. First record for Bangladesh and western range extension from nearest populations in Myanmar (of which the border is > 240 km w of Comilla) (Das 2002. A Photographic Guide to Snakes and Other Reptiles of India. New Holland Publishers [UK] Ltd., London. 144 pp.). Supported by Cleveland Metroparks Zoo and Rufford Foundation to the second author, which partially supported the first author. Bangladesh Forest Department issued permission (CCF [Wildlife]/ 2M–47/2006) for this work to the second author. Thanks are due to Md. Kamal Hossain from JU for his enthusiastic assistance in the field.

Submitted by **STEPHEN MAHONY**, 3 Park View Lawns, Greenpark, Clondalkin, Dublin 22, Ireland (e-mail: stephenmahony2@gmail.com); and **A. H. M. ALI REZA**, Department of Natural Resources Management, Texas Tech University, Lubbock, Texas 79409, USA (e-mail: ali.reza@ttu.edu).

NOROPS SAGREI (Brown Anole). USA: ALABAMA: Lee Co.: Opelika, Plant World Nursery. 7509 Lee Road 146. Approximately 100 m NW of Parkers Crossroad (intersection of Lee Rd 146 & Lee Rd 166). Collected first by Roger Birkhead, then by John Steffen, verified by Craig C. Guyer. Voucher specimens deposited in Natural History Museum at Auburn University (AU 37296, 37297). First published record for Alabama. Nearest localities are 286 km SE in Valdosta, Georgia (Echternacht et al. 1995. Herpetol. Rev. 26:107) and 270 km SE in Panama City, Florida (Means 1990. Herpetol. Rev. 21:96). On 23 January 2006, RB collected a solitary male (AU 37293). On 25 March 2006, JS sighted a minimum of 30 adult males and 20 adult females in approximately one hour search time. Animals were seen perching on plant scaffolding, nursery walls and tables, and at least one pair was seen copulating on greenhouse scaffolding.. Brown Anoles are common invaders throughout Florida (Lee 1985. Copeia 1985:182–194), and have recently been found in Georgia (Echternacht et al., *op. cit*; Campbell and Hammontree 1995. Herpetol. Rev. 26:107), Louisiana (Platt and Fontenot 1994. Herpetol. Rev. 25:33), and Texas (Krusling et al. 1995. Herpetol. Rev. 26:108). It is speculated that lizards in Georgia and Louisiana have colonized these localities when transported as propagules from Florida plant nurseries. This current sighting definitively implicates plant nurseries as propagules for colonization.

Submitted by **JOHN STEFFEN** and **ROGER BIRKHEAD**, 331 Funchess Hall, Department of Biological Sciences, Auburn University, Auburn, Alabama 36849, USA.

PLESTIODON OBSOLETUS (Great Plains Skink). MÉXICO: SONORA: Municipality of Hermosillo, 34 km (by Son. Hwy 104) E Hermosillo (29.049928°N, 110.604418°W). 4 July 1991. Adrian Quijada and Ivan Parra. Verified by C. H. Lowe. UAZ 49170. First record for the Municipality of Hermosillo, extending the range ca. 146 km (airline) SW from the vicinity of Gúasabas, Sonora (Cliff 1953. Copeia 1953:186–187). The lizard was found in a transition zone between Sonoran Desert scrub and Sinaloan thorn scrub.

UTA STANSBURIANA (Side-blotched Lizard). USA: TEXAS: COCHRAN CO.: 4 road km N FM 769 on State Line Road (33°36'22.6"N; 103°02'42.3"W). 10 June 2006. David Laurencio and Toby J. Hibbitts. Verified by James R. Dixon. Texas Cooperative Wildlife Collections, TCWC 91462–91464. New county record, closest known populations are in Roosevelt County, New Mexico. (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M University Press, College Station, Texas. 421 pp.). The specimens were collected during research on *Sceloporus arenicolus* with funding from Texas Parks and Wildlife Department.

Submitted by **TOBY J. HIBBITTS, DAVID LAURENCIO**, and **LEE A. FITZGERALD,** Texas Cooperative Wildlife Collections, Department of Wildlife and Fisheries Sciences, Texas A&M University, 2258 Tamu, College Station, Texas 77843-2258, USA (e-mail: thibbitts@tamu.edu).

SERPENTES

BOTHROPS ALTERNATUS. BRAZIL: RIO DE JANEIRO: Três Rios municipality (22°07'S, 43°12'W). 05 July 1960. Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil (MNRJ 8337). Verified by R. Fernandes. Species previously known from northern and central Argentina (provinces of Buenos Aires, Catamarca, Córdoba, Corrientes, Chaco, Entre Rios, Formosa, La Pampa, Misiones, San Luis, Santa Fe, Santiago del Estero, and Tucumán), throughout Uruguay, southern Paraguay, and southern, southeastern, and central Brazil (States of Rio Grande do Sul, Santa Catarina, Paraná, São Paulo, Minas Gerais, Mato Grosso, and Goiás) (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere, Vol. 1. Cornell Univ. Press, Ithaca, New York. p. 366; Hoge and Belluomini 1960/62. Mem. Inst. Butantan 30:97–102; Nogueira and Valdujo 2001. Herpetol. Rev. 32:58). First state record, ca. 120 km SE from the closet previous record (Minas Gerais: Barbacena municipality; Hoge and Belluomini, *op. cit.*).

Submitted by **ADRIANO LIMA SILVEIRA** (e-mail: biosilveira@yahoo.com.br) and **PAULO R. EVERS JR.,** Setor de Herpetologia, Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Quinta da Boa Vista, São Cristóvão, CEP 20940-040, Rio de Janeiro, RJ, Brazil (e-mail: pauloevers@hotmail.com).

CHARINA BOTTAE (Rubber Boa). USA: IDAHO: LEWIS CO.: Mission Creek Rd, 1.8 km N of Slickpoo (46°19.014'N, 116° 42.665'W). 24 September 2006. Robert E. Weaver. Verified by Kenneth V. Kardong. Voucher specimen deposited in the Central Washington University Department of Biological Sciences Herepetology Collection (CWU 1693). Juvenile female collected DOR (265 mm SVL, 13.6 g). First county record. Although regional field guides depict the distribution of *Charina bottae* as continuous throughout the Pacific Northwest (Storm et al. 1995. Reptiles of Washington and Oregon. Seattle Audobon Society, Seattle, Washington. 176 pp.), several counties in north-central Idaho form a significant gap in distribution data for this species (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. University of Idaho Press, Moscow, Idaho. 332 pp.). This locality fills a gap between the nearest record in Nez Perce Co., 12.1 km NW near Lewiston, and historical records in Adams Co.

Submitted by **ROBERT E. WEAVER** (e-mail: weaver@wsu.edu) and **ALEX DORNBURG** (e-mail: dornburgalex@yahoo.com), School of Biological Sciences, Washington State University, Pullman, Washington 99164, USA.

CHIRONIUS QUADRICARINATUS. BRAZIL: BAHIA: Municipality of Mucugê, Caraíbas Farm (13°08'09"S, 41°24'15"W). 15 December 2005. 1100 m elev. M. A. de Freitas and T. Figueiredo Santos. Museu de Zoologia da Universidade de São Paulo, São Paulo, Brazil (MZUSP 15049). Verified by A. J. Suzart Argôlo. Previously known from south-central Brazil, including São Paulo, Mato Grosso, Minas Gerais, Rio de Janeiro, and southeastern Bahia state (Dixon et al. 1993. Revision of the Neotropical Snake Genus *Chironius* Fitzinger [Serpentes, Colubridae]. Museo Regionale di Scienze Naturali – Torino; Argôlo 1998. Herpetol. Rev. 29:175). Second record of the species from northeastern Brazil, extends its distribution ca. 400 km N of Canavieiras, Bahia state (Argôlo 1998, *op. cit.)*.

Submitted by **MARCO ANTÔNIO DE FREITAS,** Programa de Pós-graduação em Zoologia, UESC (Universidade Estadual de Santa Cruz) CEP 46.500-000 Rodovia Ilhéus/Itabuna, Ilhéus, Bahia, Brazil (e-mail: **(**philodryas@hotmail.com**)**; **THAÍS FIGUEIREDO SANTOS SILVA,** Biogeographia Publicações e Consultoria Ambiental, Rua E quadra D lote 11, Jardim Aeroporto, CEP 42700-000, Lauro de Freitas, Bahia, Brazil (e-mail: (thaisfsilva@hotmail.com); and **MIGUEL TREFAUT RODRIGUES,** Instituto de Biociências, Museu de Zoologia da Universidade de São Paulo (USP) CEP 05586-060, São Paulo, SP, Brazil **(**e-mail: mturodri@usp.br**).**

CROTALUS INTERMEDIUS GLOYDI (Oaxacan Small-headed Rattlesnake). MÉXICO: VERACRUZ: MUNICIPALITY OF ATZOMPA: 3 km S of Atzompa (18°43'7.9"N, 97°12'20.9"W), 2571 m elev. 02 May 2004. Uri Omar García Vázquez. Verified by Luis Canseco Márquez. Colección Herpetológica del Museo de Zoología Alfonso L. Herrera, Facultad de Ciencias, UNAM (MZFC 19841). New state record, extending the known range of this subspecies slightly east of localities in southeastern Puebla (Campbell and Lamar 2004. Venomous Reptiles of the Western Hemisphere. Cornell Univ. Press., Ithaca, New York. 870 pp.). The snake was found in pine-oak forest.

Submitted by **ROBERT W. BRYSON, JR.**, School of Life Sciences, University of Nevada, Las Vegas, 4505 Maryland Parkway, Las Vegas, Nevada 89154-4004, USA (e-mail:

brysonjr@unlv.nevada.edu); and **URI OMAR GARCÍA-VÁZQUEZ**, Museo de Zoología, Facultad de Ciencias, UNAM, A.P. 70-399, México D.F. 04510, México (e-mail: urigarcia@gmail.com).

DENDRELAPHIS NGANSONENSIS (Nganson Bronzeback). CHINA: YUNNAN: Lung Ling Ting. 21 March 1917. Roy C. Andrews and Edmund Heller. AMNH R–21045. HAINAN ISLAND: NODOA. January 1922–July 1923. Clifford H. Pope. Verified by Gernot Vogel. AMNH R–27754. First country record. Currently known from Ngan Son (Bac Kan Province, type locality), Tam Dao (Vinh Phuc Province), Cuc Phuong N.P., Ky An-Ke Go and Chin Xai (Ha Tinh Province), Phong-Nha - Khe Bang N.P. (Quang Binh Province), Bach Ma (Thua Thien-Hue Province), and "Col des Nuages, near Tourane" (= Danang), Vietnam (Bourret 1936. Les serpents de l'Indochine. Henri Basuyau, Toulouse. Vol. 2., pp. 505; Ziegler and Vogel 1999. Russ. J. Herpetol. 6:199–208; Ziegler et al. 2004. Hamadryad 28:19–42). Also recorded from Laos from the "mountainous provinces of Xieng-Khouang" (= Xien Khoang Province) (Deuve 1970. Serpents du Laos. Office de la Recherche Scientifique et Téchnique Outre–Mer. Memoires ORSTOM No. 39, Paris. 251 pp.). Pope (1935. The Reptiles of China. Natural History of Central Asia. Vol. 10. American Museum of Natural History, New York. li + 604 pp.; 27 pl.) referred to these specimens as *Dendrophis boiga boiga*. New record for China (Daming 2002. Atlas of Reptiles of China. Henan Publishing House of Science and Technology, C.W.P. Zhengzhou. 346 pp.; Zhou and Yu 2002. Sich. J. Zool. 21:236–238).

Submitted by **PHILIP NICODEMO, JR.**, Cook College at Rutgers University, New Brunswick, New Jersey, USA (e-mail: philnico@eden.rutgers.edu); and **RAOUL H. BAIN**, Center for Biodiversity and Conservation, Division of Zoology (Herpetology), American Museum of Natural History, W79th Street at Central Park West, New York, USA (e-mail: bain@amnh.org).

HYPSIGLENA TORQUATA (Night Snake). USA: WASHINGTON: Columbia Co.: Tucannon River Rd (46°26.792'N, 117°46.165'W). Alex Dornburg. Verified by Kenneth V. Kardong. Voucher specimen deposited in the Central Washington University Department of Biological Sciences Herpetology Collection (CWU 1695). Adult female (285 mm SVL, 11.4 g) collected DOR 15 October 2006. First county record. Until very recently, few specimens of *H. torquata* have been recorded from SE Washington, and confusion surrounds the official regional documentation of this species. Some regional field guides show a single record for Asotin Co., and none for Columbia Co. (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. University of Idaho Press, Moscow, Idaho. 332 pp.), while some report no specimens from Asotin Co., but one for Columbia Co. (Hallock and McAllister 2005. Washington Herp Atlas http://www.dnr.wa.gov/nhp/refdesk/herp/). Regardless, no voucher specimens (photo or otherwise) exist for either county. Given this confusion and the absence of any voucher, we consider this to be the first specimen recorded from Columbia County, Washington.

Submitted by **ROBERT E. WEAVER** (e-mail: weaverr@wsu.edu), and **ALEX DORNBURG** (e-mail: dornburgalex@yahoo.com), School of Biological Sciences, Washington State University, Pullman, Washington 99164, USA.

LAMPROPELTIS CALLIGASTER (Prairie Kingsnake). USA: TEXAS: Montgomery Co.: 1.6 road km N of junction of FM 149 on FM 1774 (30°10'45.12"N, 95°41'50.28"W). 5 April 2007. D. G. Henderson. Verified by Toby J. Hibbitts. Texas Cooperative Wildlife Collection, TCWC 91799. New county record (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M University Press, College Station, Texas. 421 pp.).

PLATYCEPS TAYLORI (Taylor's Racer). ERITREA: Gahtelay (15°31'N, 39°10'E), caught in a dry wadi. 08 November 2006. Beat Schätti. MHNG 2680.55. Verified by Andreas Schmitz. Northernmost known locality of the species and first record from N of Danakhil depression; extends range by at least 400 km northwest of closest record from Assab (Largen and Rasmussen 1993. Trop. Zool. 6[2]:313–434).

Submitted by **BEAT SCHÄTTI**, Apartado postal 383, San Miguel de Allende, 37700 Guanajuato, Mexico; e-mail: beatschaetti@hotmail.com.

PYTHON MOLURUS BIVITTATUS (Burmese Python). USA: FLORIDA: Monroe Co.: Key Largo, 0.27 mi E CR 905 and Loquat Drive, Dagny Johnson Key Largo Hammock Botanical State Park (25°10'28.158"N, 80°21'58.92"W, WGS84; elev. < 1 m). 13 April 2007. Daniel U. Greene, James G. Duquesnel, Joanne Potts, and Clay Degayner. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 151037). First record from the Florida Keys (Snow et al. 2007. *In* R. W. Henderson and R. Powell [eds.], The Biology of Boas and Pythons, pp. 416–438. Eagle Mountain Publ., Eagle Mountain, Utah). A single male python (200 cm SVL, 5.7 kg) found while radio-tracking a Key Largo woodrat (*Neotoma floridana smalli*). Necropsy revealed the radio collar and animal, along with a second (non-collared) *N. f. smalli*, which is both Federally and State listed as Endangered. Because of the potential threat that *Python molurus* poses to native species in Florida, especially on small islands, this record heightens concern for the endemic and endangered fauna in the Florida Keys (Reed 2005. Risk Analysis 253:753–766).

Submitted by **DANIEL U. GREENE**, Daniel B. Warnell School of Forestry and Natural Resources, University of Georgia, Athens, Georgia 30602-2152, USA (e-mail: greened@warnell.uga.edu); **JOANNE M. POTTS**, Centre for Research into Ecological and Environmental Monitoring, University of St. Andrews, St. Andrews, Fife, FY16 9LZ, Scotland (e-mail: Joanne@mcs.st-andrews.ac.uk); **JAMES G. DUQUESNEL**, Florida Department of Environmental Protection, John Pennekamp Coral Reef State Park, P.O. Box 487, Key Largo, Florida 33037, USA (e-mail: james.g.duquesnel@dep.state.fl.us); and **RAY W. SNOW**, Everglades National Park, 40001 State Road 9336, Homestead, Florida 33034, USA (e-mail: Skip_Snow@nps.gov).

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blindsnake). USA: FLORIDA: Alachua Co.: Gainesville: SR 121 N of intersection with SR 24 (1911 SW 34th St.) (29°38'04.07"N, 82°22' 15.55"W). 16 May 2007. Collected by Louis A. Somma. Verified

by Kenneth L. Krysko, Florida Museum of Natural History, University of Florida. One adult within a termite colony, beneath rock. UF 151211; additional specimens (UF 151212–14) were also found. All specimens were collected between 1200–1240 h at the Division of Plant Industry (DPI), Florida Department of Agriculture and Consumer Services. In 2006, another adult *R. braminus* was collected by an employee at this site, near a greenhouse, and was kept in captivity until it escaped. *Rhamphotyphlops* is occasionally encountered by employees of DPI and it may be expanding its range, as there is one specimen (UF 147001) collected from the University of Florida campus (Powell Hall) adjacent to the DPI site (29°38'7.9080"N, 82°22'12.4320"W) on 10 May 2006, by J. Weber.

The first evidence of this species from Gainesville is an unpublished single specimen record (29°39'23.0761"N, 82°22'33.0240"W), from November 1999, I. A. Minno (UF 120116). The first published account referenced a specimen found at the USDA lab on the University of Florida campus (Townsend et al. 2002. Herpetol. Rev. 33:75). Although these specimens reported here do not expand the range of this species, they establish the presence of a population of *R. braminus* in Gainesville, Alachua Co. This Southeast Asian, parthenogenic typhlopid has been collected from at least 17 counties in Florida (Ernst and Brown 2000. Herpetol. Rev. 31:256; Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Inst. Books, Washington, DC; Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publ. Co., Malabar, Florida; Krysko et al. 2005. Herpetol. Rev. 36:85–87).

Submitted by **LOUIS A. SOMMA**, Department of Zoology, PO Box 118525, 223 Bartram Hall, University of Florida, Gainesville, Florida 32611-8525, USA; e-mail: las@zoo.ufl.edu.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blindsnake). MÉXICO: OAXACA: Municipality of Villa de Tututepéc de Melchor Ocampo, Río Grande (16°00'45"N, 97°25'59"W), 29 m elev. 03 January 2007. Martín Cruz Santiago. Verified by Adrian Leyte-Manrique. Colección Herpetológica del Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo (CIB-CH1376). First record for the municipality and a 205 km range extension S of the only other verified Oaxacan record from Cuicatlán (Mendoza Quijano et al. 1994. Herpetol. Rev. 25:34), which is located on the Gulf versant of the state. The closest known localities to this record are from adjacent Guerrero (Dixon and Hendricks 1979. Zool. Verh. 173:1–39). Literature records indicate that this exotic species has become well established along the Pacific lowlands from Sinaloa (Dixon and Hendricks, *op. cit.*), Jalisco (Dundee and Flores-Villela 1991. Herpetol. Rev. 22:26), Michoacán (Duellman 1965. Univ. Kansas Publ. Mus. Nat. Hist. 15:629–709), Guerrero (Dixon and Hendricks, *op. cit.*), into Oaxaca. Casas-Andreu (2004. *In* Garcia-Mendoza et al. [eds.], Biodiversidad de Oaxaca, pp. 375–390. Inst. Biol. UNAM, México, D.F.) indicated that this species occurs on the Pacific coastal plain of Oaxaca, but cites no localities. The snake was found crawling on a street in the town of Río Grande.

The introduction of invasive species is, after habitat destruction, the second most important cause of biodiversity loss on the planet (Devine 1998; IUCN 2000; Mack et al. 2000). The main problems related to the introduction of invasive species are competition with local fauna, introduction of pathogens and genetic pollution of autochthonous populations (Arano et al. 1995; Butterfield et al. 1997; Dodd and Seigel 1991; Elton 1958; Manchester and Bullock 2000). According to one estimate, 39% of all known extinctions that have taken place in the last 300 years have been as a result of the introduction of exotic species (Guijarro 2001). Especially injurious are the introductions of invasive species that disperse well and adapt quickly to new environments (Kolar and Lodge 2001; Sax and Brown 2000).

Discoglossus pictus is a North African species that was intro-

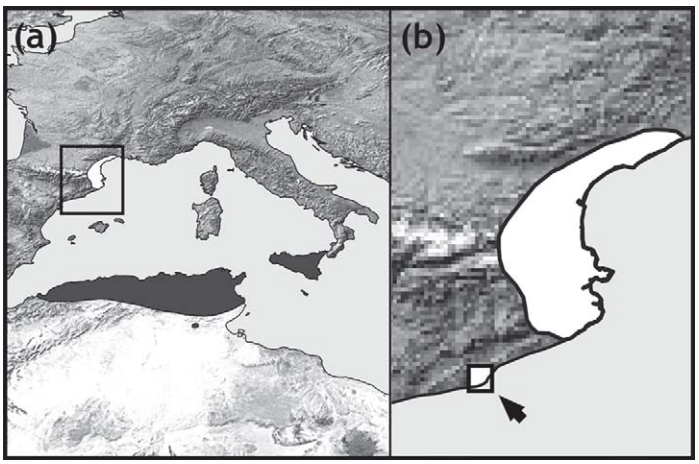

FIG. 1. Distribution of *Discoglossus pictus* in the western Mediterranean basin (left) and in the northeastern Iberian Peninsula (right). The black arrow shows the new 10 × 10 UTM (31T DF21) occupied by *D. pictus.*

duced from Algeria to a small village in Continental Europe (Banyuls Sur Mer), approximately 100 years before present (Wintrebert 1908), and now has a continuous range extending > 7000 km^2, from SW France to NE Iberia (Fig. 1) (Barbadillo et al. 1999; Fradet and Geniez 2004; Geniez and Cheylan 1987; Knoepffler 1962; Lanza 1989; Llorente et al. 1995, 1997; Montori et al. 2007; Salvador and García-París 2001; Wintrebert 1908). New data on the distribution of the introduced population of *D. pictus* suggest that it is extending its range at a similar rate to other amphibians (Leblois et al. 2000; Llorente et al. 1995, 2002; Montori et al. 2007). These studies indicate that populations have progressed within the province of Girona 60 km to the west and 140 km to the south in the last century, being its southern expansion the most accentuated (Montori et al. 2007). This progress has moved the southern limit of the distribution range of *D. pictus* in Iberia on the north of Barcelona province (Fig. 1).

In this study we report a recent introduction event of *Discoglossus pictus* in the Llobregat River Delta, 60 km south of its present distribution range, and discuss the effects that this introduction might have on the local amphibian fauna, as well as the possibility that this new population might act as a new focus of dispersal towards the south.

This study was part of a larger project on the short and long-term ecological and biological impact that the creation of new infrastructures has on the local amphibian fauna of the Llobregat River Delta (Llorente 2005). Between 2004 and 2005, extensive field surveys were carried out by means of habitat transects with constant capture effort. All amphibian species could be easily identified with the only exception of several specimens of the genus *Discoglossus* found during the surveys. The genus *Discoglossus* includes seven relatively similar species all found in the Mediterranean Basin: *Discoglossus galganoi* and *D. jeannae*, endemic to the Iberian Peninsula, *D. montalentii* and *D. sardus*, endemic to the Tyrrhenian islands, *D. scovazzi* endemic to North Africa, *D. nigriventer* endemic to Israel (probably extinct) and *D. pictus*, found in North Africa, with introduced populations in continental Europe and some Mediterranean islands (Fromhage et al. 2004; Zangreti et al. 2006). Fortunately, all seven species are easily diagnosable through the comparison of the mitochondrial 16S rRNA gene region (Zangreti et al. 2006; Fromhage et al. 2004).

Genomic DNA was extracted from small non-invasive pieces of tissue from three specimens of *Discoglossus* sp. from the Llobregat Delta and from two specimens of *Discoglossus pictus auritus* from a population in Riudarenes, Girona province. All samples were processed following standard protocols described in Carranza et al. (1999). Gene fragments were amplified by the polymerase chain reaction (PCR) and were sequenced using the same standard protocols and conditions as in Carranza et al. (1999, 2000). Primers 16Sa 5'- CGC CTG TTT ATC AAA AAC AT-3' and 16Sb 5'-ACG TGA TCT GAG TTC AGA CCG G-3' were used in amplification and sequencing of approximately 558 base pairs (bp) of the 16S rRNA gene (Palumbi 1996). The 16S rRNA mtDNA sequences from the Llobregat Delta and the population from Girona were aligned together with 16S rRNA sequences from all seven extant species of *Discoglossus* downloaded from Genbank (AY333712 – AY333724; Fromhage et al. 2004) using ClustalX (Thompson et al. 1997) with default parameters (gap opening = 10; gap extension = 0.2), and their sequences compared with the computer program PAUP* 4.0b10 (Swofford 1998).

The first observations of *Discoglossus* sp. in the Llobregat Delta occurred on 21 April 2004 at 41°17'15.71"N, 02°06'7.78"E (see Fig. 2). Other surveys carried out in 2004 near this location detected three new individuals and, in 2005, 11 individuals (two males, eight females and one juvenile) and one breeding site where tadpoles and metamorphs were detected. The collected specimens were housed in museological institution of the University of Barcelona (Animal Biodiversity Resource Center - www.ub.es/crba/). All observations of *D. pictus* in the Llobregat River Delta were close to water—in floodplains, drainage channels, and pools.

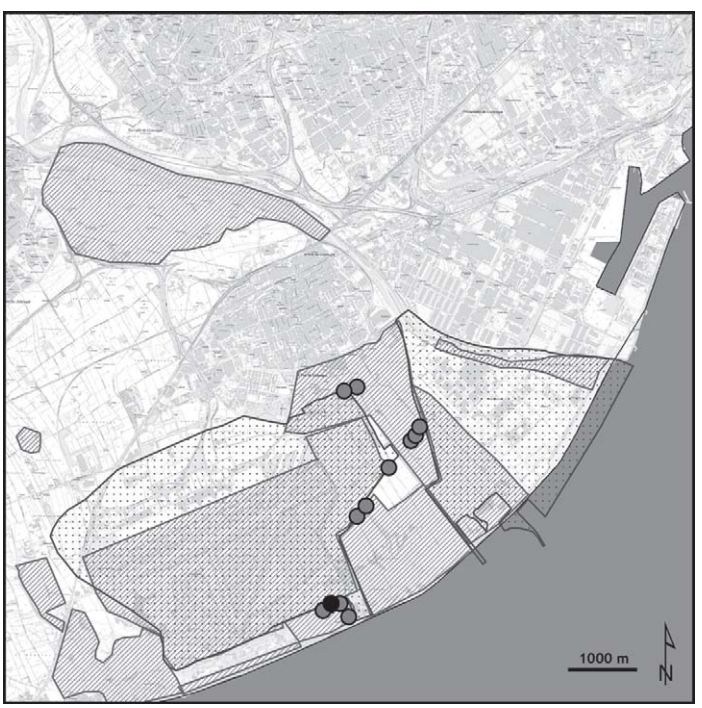

FIG. 2. Specific localities (gray circles) known for *Discoglossus pictus* in the Llobregat River Delta. Breeding locality marked with a black circle. Reticulated areas represent prospected zones cover by the study.

The mitochondrial DNA sequence analysis of three specimens (see above) from the Llobregat Delta showed that all of them were identical in the 558 bp of 16S rRNA sequenced to the specimen of *Discoglossus pictus auritus* from Girona (the control population) and showed two differences with the sample of *Discoglossus pictus auritus* from France (Genbank accession number AY333723), which is also part of the population that was introduced into continental Europe in the Nineteenth Century (Wintrebert 1908). These results expand 60 km further south the known distribution range of *D. pictus* (Fig. 1), and suggest that this is probably another case of human-mediated introduction. Two possible origins of introduced individuals are suggested. One is the indirect introduction by heavy machinery coming from northeast of Catalonia during the construction of new infrastructures in Delta. Second possible origin is voluntary introduction of individuals. In the surrounds of Barcelona it is usual to detect punctual introductions of herpetological species. For example *Triturus marmoratus* and *Lissotriton helveticus* were cited in Barcelona Metropolitan Park out of their distribution ranges.

The Llobregat Delta is located within the potential distribution area estimated by Montori et al. (2007) for this species. This will probably facilitate the establishment of a large viable population that might serve as a springboard for future expansions to other suitable habitats further south. We have verified that the species has been successfully reproducing in the Llobregat Delta, since several juveniles, metamorphs and tadpoles were found in this area.

This new introduced population implies the existence of a second centre of expansion that makes management of the species difficult. Moreover, this area has experienced a substantial decrease in its amphibian diversity as a result of the recent disappearance of three species (*Epidalea calamita*, *Bufo bufo*, and *Pelobates cultripes*) through habitat disturbance and deterioration of water quality. Future surveys in this area will indicate if the range of the species is expanding and if it has been able to establish new populations or, on the contrary, its dispersal has not progressed further. New metamorphs were detected during 2007 proving the persistence of the new population

When the introduction of an allochtonous species takes place, it is important to monitor it from the beginning. This fact facilitates the planning of immediate management measures. The reason for concluding the presence of *Discoglossus pictus* in the Llobregat Delta is the result of a human-mediated introduction and not natural range expansion is because the present expansion front of *D. pictus* in Catalonia is relatively distant (60 km to the north), without intermediate populations. Although the Llobregat River Delta is within the calculated potential distribution range for this species in Catalonia (Llorente et al. 1995; Montori et al. 2007), at the present expansion rate estimated for *D. pictus* (1.53 km/year ± 0.8 km; Montori et al., *op. cit.*), it would take approximately 30 years to disperse naturally to the Llobregat Delta from its closest populations located in the northern limit of the Barcelona province (see Fig. 1).

Acknowledgments.—We are grateful to Pere Albornà, Sabina Artal, and Dani Burgas for their help in this field survey. This work was funded by the Departament de Medi Ambient, Generalitat de Catalunya, project number: FBG302577. Scientific research permits were issued by the Departament de Medi Ambient, Generalitat de Catalunya.

Range Extensions for Eight Species of Turtles in Gasconade, Osage, and New Madrid Counties, Missouri

ZACHARY W. FRATTO
and
BRENNAN K. SWALLOW
Open Rivers and Wetlands Field Station, Missouri Department of Conservation
3815 East Jackson Boulevard, Jackson, Missouri 63755, USA

During a 2006 Wisconsin-type fyke net turtle exclusion device study conducted in Gasconade, Osage, and New Madrid counties, Missouri, ten new county records for turtles were established. The specimens listed below represent the first reported occurrence of the species within the county listed. Turtles were photographed and records were submitted to University of Missouri-Columbia (UMOC) collection. All voucher photographs were verified by Jeffrey T. Briggler and catalogued into the collection. Except where specified all animals were captured by the authors. All records were found within the ranges predicted by Ernst et al. 1994.

Apalone mutica mutica (Midland Smooth Softshell). GASCONADE CO: Gasconade River, Sec. 20 T44N R6W. 01 June 2006. UMOC 1083P.

Apalone spinifera hartwegi (Western Spiny Softshell). OSAGE CO: Gasconade River, Sec. 34 T43N R7W. 19 May 2006. Collected by Zach Fratto and Phil Pitts. UMOC 1073P.

Chelydra serpentina serpentina (Eastern Snapping Turtle). GASCONADE CO: Gasconade River, Sec. 20 T44N R6W. 01 June 2006. UMOC 1062P.

Graptemys ouachitensis ouachitensis. (Ouachita Map Turtle). GASCONADE CO: Gasconade River, Sec. 20 T44N R6W. 01 June 2006. UMOC 1062P.

Graptemys pseudogeographica pseudogeographica (False Map Turtle). NEW MADRID CO: Donaldson Point Conservation Area, Sec. 6 T22N R15E; Bottomland Hardwood Mississippi River floodplain water body. 16 May 2006. University of Missouri-Columbia collection 1057P. GASCONADE CO: Gasconade River, Sec. 20 T44N R6W. 01 June 2006. UMOC 1064P.

Pseudemys concinna concinna (Eastern River Cooter). GASCONADE CO: Gasconade River, Sec. 20 T44N R6W. 01 June 2006. UMOC 1068P.

Sternotherus odoratus (Stinkpot). OSAGE CO: Gasconade River, Sec. 31 T43N R7W. 14 June 2006. University of Missouri-Columbia collection 1072P. GASCONADE CO: Gasconade River, Sec. 22 T44N R6W. 28 June 2006. UMOC 1061P.

Trachemys scripta elegans (Red-eared Slider). GASCONADE CO: Gasconade River, Sec. 20 T44N R6W. 01 June 2006. UMOC 1070P.

The Frogs of New Guinea and the Solomon Islands, by James Menzies. 2006. Pensoft Publishers, Sofia, Bulgaria (www.pensoft.net). x + 346 pp., 48 pp. pls. Hardcover. 45.00 € (approx. US $62). ISBN 954-642-273-8.

FRED KRAUS
Bishop Museum, 1525 Bernice Street
Honolulu, Hawaii 96817, USA
e-mail: fkraus@hawaii.edu

The Papuan region comprises New Guinea and immediately adjacent islands, and the Bismarck, Admiralty, Solomon, and Aru islands. It contains a unique biota recognized since the time of Alfred Wallace. Its frog fauna is among the world's largest, with ~350 species described to date and an approximately equivalent number no doubt waiting to be discovered or described. Yet it is also among the poorest known anuran faunas in the world because of its large size, difficulty of geographic access, and paucity of researchers. Among those researchers is Dr. James Menzies, who taught for most of his career at the University of Papua New Guinea and who has probably the greatest amount of wide-ranging field experience with that region's frog fauna. He has now produced a book treating the frog fauna of this region that is a tremendous expansion of his 1975 *Handbook of the Common Frogs of New Guinea*, which has long been out of print and was, as the title suggests, of more limited scope. Included in the new treatment are mention of all 331 frog species known by the end of 2005 to occur in the Papuan region or in the Moluccas for those genera (e.g., *Callulops*, *Litoria*, *Oreophryne*, *Platymantis*) having a few relatives that have filtered westward.

The book is divided into seven sections of widely varying length. An introduction gives the goal of the book to "discuss the frog fauna of New Guinea in its regional context by assembling all that is recorded in the literature." This is followed by sections treating 2) the diversity and biology of Papuan frogs; 3) background information on the topography, geology, climate, and vegetation of the region; 4) origin and biogeography of Papuan frogs; 5) a brief discussion of the layout for the systematic accounts; 6) the systematic accounts themselves, which comprise the large majority of the book; and 7) a one-page description of how to preserve frogs. The sections are followed by an appendix providing spectrograms of many Papuan frog calls, distribution maps for selected genera and species, a glossary of some terms used in the book, a gazetteer of many place names referred to in the book, references cited in the text, and an index. Tacked on too are two pages of newly described species either overlooked in the original compilation (6 spp., p. 346) or described after the book was sent to press (5 spp., p. 273). The meat of the book, of course, are the systematic accounts. Each includes scientific name, author, and year of description; complete citation for the original description; a brief diagnosis of the species (or genus, in some cases); ecological notes; and verbal description of the geographic range. Frequently, descriptions of the acoustic impression of a species' call is provided, which makes interpretation of the spectrograms easier. Species accounts are typically brief; poorly known species frequently verge on telegraphic owing to paucity of available information.

I am sorry to report the book to be disappointing and frustrating at many levels. It is replete with errors of fact, logical inconsistencies, poor writing and editing, and omission of useful information. It is difficult to choose where to begin but I will start with the less important points and proceed to the more important.

Spelling, grammatical, and writing errors are common throughout the book. The first are most often a minor annoyance but the few cases involving species or place names could confuse the novice. Into this category fall "valkuriorum" for "valkuriarum" throughout p. 10, "Carstenz" for "Carstensz" on p. 15, "macosceles" for "macrosceles" on p. 90, "Bainings" for "Baining" on p. 91, "nexippus" for "nexipus" on p. 90, and "elkae" for "elkeae" on pp. 107 and 342.

Spelling inconsistencies are of modest frequency. In this category fall "San Cristobal" vs. "San Christobal" on pp. 80 and 81 as well as "Jayawija", "Jajawijaya", and "Jayawidjaya" on pp. 262 and 264. Most annoying is the consistent use throughout the book of "Guenther" as author following a species name, with "Günther" invariably used in the subsequent line providing complete reference for the original description. Too, it would have been helpful to distinguish A. Günther from R. Günther. Punctuational mistakes are common; in particular, commas are seemingly randomly interspersed throughout the text.

Menzies makes the useful distinction throughout the taxonomic accounts of providing both maximum male and female body sizes. This is important because females are larger than males for most Papuan frogs. However, this standard is inconsistently applied and accounts for several species in which both sexes are known provide only one body size measurement (e.g., *Nyctimystes pulcher*, p. 165); in other cases accounts don't specify sex, leaving the reader to guess to which the information is intended to apply (e.g., *Litoria quadrilineata*, p. 122). Too, the information is usually provided as, e.g., "HBf" but sometimes as "HB female". When he notes that female hylids are up to 30% larger than males (p. 100), he presumably is referring to HB length and not mass.

The writing style in many sections of the book is poor or awkward and leads to confusing, nonsensical, or misleading statements. As one example among many: "Call consisted of a series of double notes contrasting with other species in the *gracilenta* group, with simple notes" (p. 107). Another from p. 37: "The Pliocene was a time of mountain building when the Miocene 'Mobile Belt' Islands became consolidated and developed into the central mountain ranges of present day New Guinea, although the south-east-

ern 'tail', which remained separated by a gap, where the Watut-Bulolo River Valleys now lie." This is especially common in the introductory chapters but improves considerably by the time the microhylid species accounts occur. In other parts, the language is unnecessarily vague: we learn, for example, on p. 15 that New Guinea is one of the largest islands in the world, but not the second-largest island in the world nor the largest tropical island; we discover on p. 17 that the major rivers of northern New Guinea were marine incursions until recently, but we do not learn how recently; we are told on p. 25 that the vegetation seen "on the ground" is likely to be quite different from vegetation-classification systems of Thornthwaite (1948) and Holdridge et al. (1971) but we are not told why. The descriptions of call variables (p. 11) are also unnecessarily brief and not particularly helpful to the uninitiated. Such lack of specificity detracts from the book.

Numerous internal inconstencies occur in the book. A sampling of these include implied polyphyly of Papuan microhylids (p. 37) vs. stated monophyly (p. 39); discussion of alpine vegetation and alpine-dwelling frogs under the section labelled "Species of the subalpine regions (>3000 m)" (p. 45); inclusion of the Owen Stanley Mts. in the range of *Lechriodus aganaposis* on p. 61 but its omission from Map 2; the claim for eight and for seven genera of Papuan ranids in the same paragraph on p. 64; including *Platymantis acrochordus* for comparison with *Discodeles malekuna* in one sentence and then inadvertently comparing it with *P. myersi* in the next (p. 82); noting that *Platymantis nexipus* has longitudinal skin folds (p. 94) while later claiming the dorsum to be smooth (p. 95); calling *Litoria exophthalmia* "mostly green" (p. 102) while the Plate 61 shows a mostly brown frog; stating that the *Litoria nigropunctata* complex is characterized by extensively webbed fingers (p. 114) while ignoring that *L. rubrops* (p. 117) and *L. vocivincens* (p. 119), both members of that group, have fingers with only basal webbing; inclusion of Milne Bay and Popondetta in the range of *Litoria congenita* (p. 122) while omitting them from Map 9; remarking that color in life of *Litoria exophthalmia* is unrecorded (p. 127) while providing a color photo of the species in life (Plate 61); claiming *Litoria modica* to have longer legs on average than *L. pratti* (p. 139) while providing a range of TL/SV for the former (0.52–0.60) that comfortably brackets the single value given for the latter (0.56); stating that *Nyctimystes papua* is smaller than *N. oktediensis* (p. 157) while providing identical HBm values for each; writing "although not known to be sympatric, their distributions overlap" (p. 227); claiming that each of *Hylophorbus picoides* and *H. wondiwoi* is the largest of Günther's new species (p. 250 and p. 252, respectively); and noting that *Xenobatrachus tumulus* occurs only in the Adelbert Mts. (p. 266) but is sympatric with *X. zweifeli* (p. 266), which is only known from the Bewani and Hunstein Mts. The plate numbers cited for the photos of *Litoria leucova* and *L. majikthise* (p. 144) do not accord with the names attached to those plates.

Menzies usefully provides a glossary of some scientific terms at the end of the book. However, some of these—holotype, terrane—are mistakenly defined. Other terms used in the book—acromiohumeralis muscle, adherent tongue, alary processes, centric fission, clavicle, diplasiocoelous, firmisternal, lumbar, mandibular bones, mandibular depressor muscle, maxillary bones, megathermal, mesohumid, mesothermal, nasal bones, omosternum, perhumid, premaxillae, presacral, procoelous, procoracoid, sacral diapophyses, sacrum, subhumid, symphyses, urostyle—are omitted from the glossary and remain undefined in the text. Two terms of non-obvious meaning, "bidomicilic" and "ecological vicars" are frequently used in the book but do not appear in the glossary, although the former is defined on p. 33, at its second usage. Similarly, the term "mid-green" is used (p. 105) but its meaning is unclear – "mid" in terms of hue? saturation? intensity? Geographic terminology is largely relegated to a series of footnotes scattered from pp. 6–33. More profitably, this fragmented approach should have been eschewed in favor of an introductory paragraph explaining the terms involved. This is frequently required in treatments of the Papuan region because of the many possible ways of parsing the assorted geographical and political entities involved.

A useful attribute of the book is the inclusion of a gazetteer for most mentioned place names. However, several localities mentioned in the book (e.g., Ok Tedi, Astrolabe Bay, Mt. Kerewa) are not included, nor are historically important localities (e.g., Bernhard Camp, Moroka, Lorentz River) whose inclusion would have provided a useful service to beginning researchers. Nonetheless, this is a resource not frequently available elsewhere and is a valuable addition making it easier for the novice to locate numerous place names used in the text and throughout the primary literature.

In a few cases, important literature is left uncited. James (1997) is mentioned on p. 36 but not included in the Literature Cited. On p. 181, it is noted that *Choerophryne* is similar to *Albericus* but the paper first arguing and presenting evidence for this relationship (Burton 1986) is not cited. Tyler and Davies' (1978) partitioning of *Litoria* into 37 heuristic species groups is largely followed by Menzies but without attribution. In a few instances, literature is mis-cited (e.g., Kraus and Allison 2001, p. 183, first paragraph). More problematic is that a few sources are incorrectly referenced. Most common of these is that the Global Amphibian Assessment for Papuan frogs, which involved nine specialists meeting at Bishop Museum in February 2003 (this reviewer did not attend) and which has a widely available summary of findings properly cited as a web source (Global Amphibian Assessment. http://www.globalamphibians.org/) is routinely cited by Menzies as "Richards (2003)." This improper citation slights the contributions made by the numerous other participants in the meeting, implies the existence of a finished product from 2003, and ignores the updated information made available on the website since that time. Similarly, the report properly cited as Allison et al. (1998) is variously cited by Menzies as either "Mack (1998)," e.g., on p. 107, or as "Richards (in Mack 1998)," e.g., on p. 121.

Of greater consequence for the uninformed reader are numerous errors of fact, most of which are concentrated in three different sections of the book: the discussion of geology, section on frog biogeography, and the species accounts themselves. I will discuss each in turn, leaving more relatively minor errors of fact to Table 1.

Menzies bases his discussion of the geological history of the Papuan region primarily on seven prior papers and books. He does consult the immensely useful and detailed summary of Pigram and Davies (1987) but fails to note the refinements provided by Pigram and Symonds (1991) and Davies et al. (1996, 1997). Menzies' summary of this history has several errors of fact or implication, the latter deriving from omission of detail. On p. 17, he notes that the central ranges of New Guinea "consist largely of

uplifted marine sediments." This is formally true but neglects to emphasize their geological diversity: they are in fact a mix of lithified limestone, ophiolitic, and volcanically derived terranes as well as remnant continental microplates. On p. 21 and again on p. 37, he implies that the central dividing ranges are due to tectonic activity during the last 10 million years (MY), but in fact uplift of these regions extends back to the Oligocene at ca. 30 MY. He claims (p. 29) that New Guinea "has consisted of isolated island chains that have had a checkered history, and only became joined at the last fall in sea level, some 15–10,000 years ago." This is a thoroughly false way of perhaps trying to convey that New Guinea consists of the northern margin of the Australian Craton, onto which have been sequentially sutured two separate island arcs. However, as noted above, those arcs accreted during the past 30 MY, not the past 15,000. The most recent docking event, involving the Huon Peninsula, occurred approximately 5 MY. Further, since sea levels have risen in the past 15–10,000 years, it is difficult to understand how New Guinea has not been recently fragmented into separate islands if their former uniting into a single island was due to lowered sea levels. The answer, of course, is that fluctuating sea levels had nothing to do with the amalgamation of New Guinea; plate tectonics did. Menzies' terminology for these two island-arc systems can also be somewhat confusing. The more recent arc system, now forming the north coast ranges of New Guinea and including New Britain and the Solomon Islands, is the "Solomons Arc." Menzies refers to different components of this system as either the "Melanesian Arc" (p. 19), a somewhat misleading and outdated term (cf. Polhemus and Polhemus, 1998), or the "East Philippine Arc" (p. 20). Lastly, the Southeast Peninsula was formed as an offshore composite of diverse accreted terranes during the Late Oligocene and later sutured to the margin of New Guinea. This biogeographically important detail goes unmentioned in the book.

The section discussing biogeographic patterns of Papuan frogs is largely speculative, and much of it is inconsistent and incredible at face value. Conjectures in this vein include that the myobatrachids *Lechriodus* and *Mixophyes* are old invasions from Australia displaced more recently by the Asian-derived microhylids (p. 32). Such ancient invasion and displacement are hard to reconcile with the close, congeneric relationships among these Papuan and Australian myobatrachids vs. the diversity of a microhylid clade containing 170 described species and 15 endemic genera. Rapid evolution indeed! There is a 2+ page discussion of whether frogs can cross marine barriers that doesn't lead anywhere much. Despite the indubitably rare nature of such events, biogeographic evidence (not discussed by Menzies) makes it clear that such events must sometimes occur (e.g., Vences et al. 2003) and no other explanation seems credible for the arrival of Oriental families of frogs (e.g., Microhylidae, Ranidae) into the Papuan region. The presence of two microhylids on New Britain is argued to be due to a "limited migration" during the Pliocene (p. 38) but the larger ensemble of 18 Australian microhylids and the large radiation of New Guinean *Litoria* and *Nyctimystes* are relegated to presumed Pleistocene invasions (p. 38). Discussion of "routes for exchange" (p. 35–36) appears a type of informal Croizatean track analysis and it is unclear whether these tracks are intended to signify overseas dispersal routes, land bridges, patterns of island-arc accretion, or a mix of all.

Biogeographic discussions should necessarily be based on understanding of phylogenetic relationships. Little such work has been done on Papuan frogs, but Menzies either misinterprets the work so done or repeats the errors of prior workers. Hence, he argues repeatedly (pp. 39, 75) that *Platymantis* is not proven monophyletic, citing an unpublished thesis by Norris (2002). But Norris did not test *Platymantis* monophyly, nor even that of the Solomon Islands species; hence, Menzies' inference is invalid. On p. 41, he discusses the "entry" of *Oreophryne* into New Guinea, implying a polyphyletic origin of the Papuan microhylids that is belied by the literature (Savage 1973; Tyler 1979; Burton 1986; Frost et al. 2006 [the last, of course, unavailable to Menzies when composing this book]), and his claim that the ancestor of the direct-developing Papuan clade probably had tadpoles (p. 33) is an unparsimonious interpretation for a presumed monophyletic clade. Most confusing of all, perhaps, is his choice to repeat a conjecture attributed to Norris (2002) that the ranid genus *Batrachylodes*, endemic to the Solomon Islands, had an origin on Borneo (p. 75)! The rationale for this conclusion is not provided.

Menzies discusses (pp. 42–48) several of the more interesting distributional patterns found within Papuan frogs. This section is useful for giving the novice a feel for some of the ecological and regional subsets of Papuan frogs, although I think it would have been improved if ecological patterns had been distinguished from geographical patterns instead of intermingled. These patterns are illustrated by reference to a few exemplar species instead of a comprehensive treatment or listing of all constituent species. This is fine, but it is hard for me to see why so much discussion was given to the depauperate and poorly known fauna of the Aru Islands (p. 48) while providing only cursory discussion of the far more speciose, endemic, and better-known faunas of the Bismarck and Solomon islands (p. 47) and no discussion of those of Yapen, Biak, D'Entrecasteaux, and Louisiade islands.

To my mind, however, the greatest fault of the book is that it cannot be used in most instances to reliably identify Papuan frogs. Only three complete keys (for 3 spp. of *Lechriodus*, 8 spp. of *Batrachylodes*, 4 spp. of *Choerophryne*) appear in the book, and these (with one minor addition) are cribbed from existing literature. Other published keys requiring no (e.g., *Barygenys*) or little (e.g., *Callulops*) modification are not repeated here. This reflects the author's stated belief (e.g., p. 102) that diagnostic keys are not possible for most of these genera. Instead, Menzies provides a table of assorted attributes on p. 53 that is intended to guide the student toward or away from particular taxa in comparison to a specimen in hand. But this table has errors (Table 1) and the genus *Oxydactyla* is omitted. A few examples of partial keys (typically modified prior keys from the literature) appear in the book but these are of limited use or are utterly misleading. For example, the key to *Platymantis* of New Britain (p. 90) distinguishes among some incredibly different species (e.g., *P. browni* and *P. mamusiorum*) using only trivial morphometric ratios not easily determined in the field and doesn't distinguish among others (e.g., *P. boulengeri*, *P. magnus*) that are separable at a glance. In that same key, diagnostic couplets are incorrect (e.g., *P. rhipiphalcus* lacks longitudinal skin folds but has a diverging fan of such folds, hence its name; *P. akarithymus* and *P. schmidti* have more than two longitudinal skin folds; *P. gilliardi* is equivalent in size to *P. mimicus*, not smaller) or internally inconsistent (e.g., one must

TABLE 1. Corrections to some errors of fact in *The Frogs of New Guinea and the Solomon Islands.*

Page	Correction
24	Most recent El Niño event was in 2002–03, not 1997–98
38	Is only 1 species of Australian *Nyctimystes*, not 3
44	*Litoria pratti* and *Nyctimystes montanus* are also endemic to Bird's Head region
46, 190	*Cophixalus cryptotympanum* restricted to Mt. Dayman area, not widespread, according to Global Amphibian Assessment
46, 155	Range of *Nyctimystes kubori* includes the Owen Stanley Mts.
53	Character 2 should read "S" for *Austrochaperina*, "R" for *Oreophryne*, and "R" for *Xenorhina*
53	Character 12 should read "R" for *Choerophryne* and "+" for *Pherohapsis*
66	Sonnini should be included as author in original citation for *Limnonectes grunniens*
79–80	*Ceratobatrachus* eating *Platymantis* is not an instance of cannibalism
83	There were 55 species of *Platymantis* described by the end of 2005, not 40
85	*Platymantis macrosceles* is not smooth but has scattered pointed warts
86	*Platymantis pelewensis* is not a Philippine species
86	Range of *Platymantis* extends well north of Mindanao
87	Original name for *Platymantis papuensis* was *P. corrugatus papuensis*, not vice versa
88, 91	*Platymantis papuensis* is not known from New Britain
91	Place name is Weitin Valley, not Weitin
92	*Platymantis browni* is known from New Britain, as noted in original description
94	*Platymantis nexipus* lacks longitudinal skin folds
95	Original name is *Platymantis rhipiphalcus*
97	Fingers of *Platymantis acrochordus* are pointed, not just without discs
134	Kraus & Allison (2004b) did not report *Litoria arfakiana* from the D'Entrecasteaux Islands
154, 167	*Nyctimystes semipalmata* is not large and it lacks a heel lappet; the description given under this species is fictional
155	*Nyctimystes kubori* also ranges throughout the Owen Stanley Mts.
174	Not all *Albericus* are brown; some are gray or green
182	*Choerophryne rostellifer* has discs on first fingers
183	Kraus & Allison (2001) did not include the upper Fly R. specimen of *Choerophryne rostellifer* in *C. proboscidea*
185	All species of Menzies' Group 2 have the first finger present, though all have it reduced to some greater or lesser extent
190	Range of *Cophixalus verrucosus* includes Woodlark and Sudest islands
230	Elevational range of *Oxydactyla crassa* extends to 2880 m
236	Type locality for *Barygenys exsul* is Rossel Island, not Sudest Island
246	*Callulops slateri* is known from many more than 6 specimens
253	*Mantophryne infulata* is known from the Finisterre Mts., not the Adelberts
254	*Xenorhina doriae* was changed to *Callulops doriae* in 1988
254	*Pherohapsis menziesi* is known from several more than 7 specimens
265	The call for *Xenobatrachus subcroceus* is C144, not C148

traverse through 6a to get to 9b but the two are contradictory).

The claim that keys cannot be written is, of course, specious but application of this claim seriously undermines the utility of the book. This is worsened by the fact that the sections on "Field recognition" for most species are usually a general color-pattern description that doesn't always focus on diagnostic features, combined with the author's astounding claim (p. 52) that color and pattern are not much help for species identification beyond a few examples. Omission of explicit diagnostic features is widespread in the book and disqualifies it from being viewed as a field guide or from providing much assistance to anyone for identification purposes. I could give many examples where diagnostic, easily discernible features of species and genera go unmentioned, but I will provide only a few to give a flavor of the problem: *Rana jimiensis* is distinguished from *R. arfaki* by relative size of the tympana alone (p. 69), a character not liable to assessment in the field, even though the two may be distinguished at a glance by the broad finger fringes and tuberculate tympana of the former; *Rana kreffti* is easily distinguished by its lateral white stripe from all Papuan congeners but this feature goes unremarked (p. 72); *Litoria impura* is distinguished from *L. thesaurensis* solely on the basis of amount of foot webbing and *L. flavescens* is distinguished from neither, even though all are closely related and unambiguous color-pattern features distinguish each (Menzies and Zug 1979; Kraus and Allison 2004a); *Litoria dorsalis* is not diagnosed from its close relative *L. timida* by its diagnostically different canthus and its size (Tyler and Parker 1972) but is contrasted instead with the "*Litoria dorsalis* complex" which contains only those two species in the Papuan region. Many additional examples exist, and I simply note that it might be possible to get a tentative identification using this book but that the serious student will necessarily require reference to the original literature for verification. So why use the book and add a step?

Identification difficulties are exacerbated by substandard supple-

mentary materials (color plates, range maps) that would normally assist in identification. Several of the color plates are informative and will help in the identification of some species. But many (most?) of these images clearly date back to the 1970s, are of poor or mediocre quality, and do not reflect the standards usual in today's books. Many photos are out of focus, too dark, have the animal partially hidden, appear to be of animals anaesthetized and draped over vegetation, or are not shot in profile. It is hard to imagine what identifying information is intended to be conveyed by Plates 36, 67, 72, 84, 89, 94, 113, 117, 127, 129, 137, 138, 139, or 166, for example. Many other plates are substandard but serviceable; few shine. Plate 154 is almost certainly *Callulops personatus*, not *C. robustus*. Given the wealth of good photographs available from other researchers of this fauna, I find it incredible that Menzies did not attempt to borrow from them so as to improve his photographic coverage.

Almost as important, the range maps in the book are not comprehensive, either in terms of species coverage or in areal coverage for a species. All are unfriendly to use, with several taxa invariably combined into each map and separated only by difficult-to-read symbols in small font. Fortunately, far better and more comprehensive range maps are available on the web at either the Global Amphibian Assessment website (http://www.globalamphibians.org/) or the Papuan Herpetofauna website (http://www.bishopmuseum.org/research/pbs/papuanherps/), so the reader with Internet access will not have to rely on those provided in this book. But that won't help those in the field with a frog in hand. (I must note, though, that in one case [*Litoria timida*] the range given on the GAA website is wrong and Menzies is correct.)

Despite the long list of problems above, I stress that I have by no means attempted an exhaustive search for errors. Most of my attention was focused on the 83 species (out of 331 treated) for which I have direct experience in the field, and I have omitted mention of several other statements, practices, emphases, and omissions in the book liable to disputation from knowledgeable researchers in this field. Hence, this review should not be mistaken as a definitive treatment of this book's errors and questionable claims.

Given this litany of faults, it might be wondered if there are any positive aspects to the book. Indeed there are. First, Menzies' description of the climatic regimes in New Guinea and effects of El Niño events is quite good. His plates illustrating different habitats around the island are uniformly excellent and they nicely capture the impression one has on the ground. This is welcome given the extent to which so many published photos of tropical forests merely illustrate an uninformative swath of dark green; Menzies has admirably avoided that problem. For those having some familiarity with frog-call analysis, the many graphs of spectrograms and waveforms provided in Appendix A will be a welcome addition, especially when taken in concert with verbal descriptions of a call's acoustic impression, available in many of the systematic accounts. Still, it must be noted that some of these spectrograms illustrate nothing more than the sound of rushing water and culling those would have improved this section. Extremely useful for the beginning student will be Menzies' practice of including complete citations for each original description. This will prove an invaluable service considering the inability of the book to serve as a reliable identification guide. Also, some of the color plates are helpful for discriminating among certain difficult-to-identify species (e.g., *Xenobatrachus*), and others (e.g., *Palmatorappia*, *Nyctimystes granti*) usefully illustrate color-pattern polymorphisms not detailed in prior literature.

In my opinion, the most valuable aspect of this book is the ecological information given for many species. Menzies has considerable breadth of experience with these animals in the field and little ecological information has been previously published for this fauna, so provision of so much of it is truly a boon for researchers active in the region. It is this aspect of the book that I think will prove of longest value for future students of this fauna.

Given the nature of the numerous criticisms raised above, it is only fair to point out the utter negligence of the publishers in providing any sort of meaningful editing or external review for this volume. Many of the book's failings could easily have been avoided by doing so. To their credit, the binding of the book does seems sturdy, although I confess that despite many temptations I did not utilize the rigorous testing procedures pioneered by Crombie (1992).

So how to rate this book overall? Its approach to the subject seems decidedly lackadaisical; fact-checking appears scarce; concern for rigor and scholarship is not evident; resort to museum specimens other than those collected by the author appears lacking. I suppose this book could provide some form of service to the novice by comprehensively summarizing the species names and literature sources and by providing some degree of faunal overview, however compromised. But much of the constituent information cannot be accepted at face value, especially for distinguishing among species and understanding the evolutionary processes creating its subject fauna. For these reasons, the book is likely to be of questionable utility to the professional scientist (ecological information excepted) and, worse, is liable to mislead those not well-versed in the subject. The book could have avoided its numerous problems while retaining its useful features if Menzies had chosen to co-author (or at least vet) it with a more meticulous person such as Richard Zweifel (who, in more than 700 pages of contributions to the Papuan frog fauna has made only two important errors, one later corrected by himself). It is a pity that option was eschewed.

A Review of Marking and Individual Recognition Techniques for Amphibians and Reptiles, by John W. Ferner. 2007. Society for the Study of Amphibians and Reptiles (ssar@herplit.com), Herpetological Circular no. 35. iii + 72 pp. Softcover. US $11.00. ISBN 0-916984-68-0.

GAD PERRY
Department of Natural Resource Management, Box 42125
Texas Tech University, Lubbock, Texas 79409-2125, USA
e-mail: Gad.Perry@ttu.edu

Much of organismal biology relies on the ability to identify individual animals. Without it, one cannot calculate home ranges, estimate population size, measure growth rate in the field, or document dispersal patterns. Consequently, many methods books include sections on marking of amphibians or reptiles, including an old mainstay, that of Ferner (1979). This slim circular (42 pages), now out of print, summarized the state of the knowledge at the time, covering major taxonomic groups and methods in a readable and easy-to-follow way. However, as Ferner points out in the preface to the current update, many things have changed in the three decades that have intervened. For one thing, technology has greatly improved, giving us tools such as the Passive Integrated Transponder (PIT) tag. Another major change has been the ascendancy of the animal rights movement and the increased control of animal care and use committees (ACUCs) and veterinarians over herpetological research. In 1979, one decided what was most appropriate and went about doing it. Today, most universities require ACUC approval of herpetological research, even though it is in most cases not actually required by law in the US. One must justify the use of techniques to non-experts and list ACUC permit numbers on papers, if possible (for the SSAR policy see http://www.ssarherps.org/pages/ethics.php). The current circular rather successfully brings this compendium up to date.

The current text is 72 pages long, of which 59 pages are devoted to the methods and the rest to references spanning 1933–2006. Many of them are taken from the pages of *Herpetological Review* but the coverage is quite wide. Besides the various herpetological journals it also includes *Nature*, *Ecology*, a variety of books, and less readily available sources such as *Froglog*, *Missouri Speleology*, and a research publication of the Texas Parks and Wildlife Department. Most of the book is organized by group, with coverage of larval amphibians (pp. 1–3, which include the egg-mass marking method of Regester and Woosley [2005]), frogs

and toads (pp. 3–13), salamanders (pp. 14–20), caecilians (seven lines on p. 20), turtles (pp. 20–28), lizards (pp. 29–37), snakes (pp. 37–45), and crocodilians (p. 46). The tuatara, a rather specialized case, does not receive a separate section. Toe clipping, a common method which has become somewhat controversial, receives expanded coverage in relevant sections. Two additional sections follow, one on the use of PIT tags (pp. 47–51) and the other on radio-transmitters (pp. 51–59, also briefly covering the use of GPS-based technology), each internally organized by taxonomic group. Twenty-two helpful illustrations, many of them taken from the previous version, are provided, as is a table listing possible combinations available for toe-clip marking using one of the techniques.

No technique is free of limitations and unintended consequences so, as Ferner emphasizes, it is important to use the correct methods for the species, environment, and study type. Ferner wisely does not attempt to list every study that uses a particular technique, instead focusing on original descriptions of methods and subsequent evaluations of their efficacy, with common techniques receiving broader attention. I paid special attention to the section on lizards, the organisms with which I have the most experience. This section begins with discussion of toe and scale clipping and is updated enough to include recent work by Langkilde and Shine (2006) which suggests that not only does clipping have little impact on stress hormone levels but that methods many favor as more apparently humane, such as PIT tag use, appear more stressful. Methods based on integument pattern, branding and painting, and tagging follow, and recent methods such as implanted elastomers, only recently applied to lizard studies, are included.

Overall, the coverage is good. Common methods are all listed, and methods that are rarely used nowadays, such as the use of radioactive tags, still receive coverage. Ferner spends enough time to familiarize the readers with the basic plusses and minuses, but often avoids detailed descriptions of issues such as surgery for radio-transmitter implantation. Ferner also carefully avoids making strong statements for or against a particular technique, letting readers draw their own conclusions. Although this can be a drawback, the author is clear from the start that "use of very complex techniques … require careful review of the original sources." This seems essential if one is to maintain the compactness of the original work, and references to more detailed work abound.

There are some drawbacks to the work, but they tend to be minor. I found the occasional misspelling ("were" instead of "where" near the bottom of page three, unfortunately a common type of problem in the age of computerized spell-checkers) and awkwardness (an outline of a gecko inserted into a figure illustrating frog markings on page four), but these are few and far between. Some references cited as "in press" in the now defunct Smithsonian Press will likely never see the light of day, an extremely unfortunate situation that is not of Ferner's doing. A reference or technique is sometimes absent or difficult to find. For example, the general reviews of Murray and Fuller (2000) and Beausoleil et al. (2004) are absent, as are some other general references on marking that include herpetological sections. The heat-branding method for iguanas cited by Hayes et al. (2000) is absent in the lizard section, but heat-based branding can be found in the snake section, complete with methodological citation. However, this rarely happens and, when it does, tends to involve a minor variant on a common technique that is listed (freeze-branding does appear in the lizard section). One recent method completely absent is the use of DNA for individual identification. Albeit still infrequent in herpetological studies, DNA is already being used for individual identification in the case of highly endangered and intensely-studied species such as some iguanas (e.g., Hayes et al. 2000). DNA-based individual identification is unlikely to soon become the standard for field studies, but will doubtlessly become more common as the technology improves and costs continue falling. Another absence that, although not crucial, could have helped readers is a summary table quickly listing each method, basic pros and cons, and pages where relevant text is displayed. Finally, my personal preference would have been to arrange things by method first and taxonomy second, as a method applied for one group may well apply to another where it has not yet been tried, and is therefore not currently listed. Doubtlessly, this would have created its own difficulties.

Despite these minor weaknesses, this is a valuable contribution. Ferner's circular is best when used as an initial screening tool for eliminating inappropriate techniques and zeroing in on more likely tools. In the case of low-tech methods such as toe-clipping, one can find everything they need here. For more complex methods, additional reading will definitely be required. Because of this, the booklet is most likely to be of primary use to those starting out in herpetological field research or seeking alternative methods to the ones they are familiar with. However, it also holds an important benefit for the seasoned professional. Having an updated, taxon-specific volume listing methods can be a huge boon in the process of obtaining ACUC approval, since most such committees are geared towards biomedical work and are unfamiliar with appropriate methods for herpetological field studies (Lindzey et al. 2002). One can refer to it as the state-of-the-art in the field, an authoritative source of acceptable methods which goes considerably beyond the less detailed considerations jointly published and occasionally updated by the herpetological associations in the US (http://www.asih.org/files/hacc-final.pdf) and elsewhere (e.g. the Australian position on toe clipping is at http://www.griffith.edu.au/school/asc/ppages/academic/jmhero/ash/pdf/Lizard_Toe_Clip_Position_Statement_1.pdf). Overall, especially given the very reasonable cost of this booklet, this is a contribution every field herpetologist should have access to.

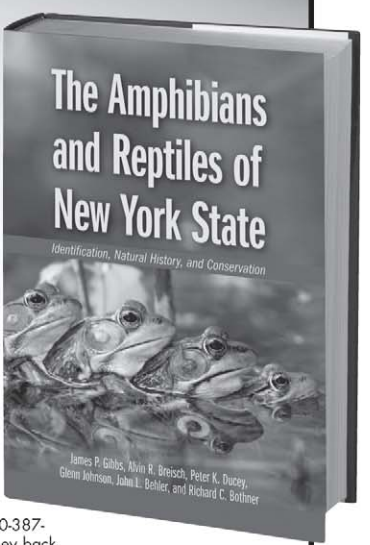
THE AMPHIBIANS AND REPTILES OF NEW YORK STATE

Identification, Natural History, and Conservation

James P. Gibbs, *SUNY-ESF Syracuse*, **Alvin R. Breisch**, *New York State Department of Environmental Conservation*, **Peter K. Ducey**, *SUNY Cortland*, **Glenn Johnson**, *SUNY Potsdam*, the late **John Behler**, *Wildlife Conservation Society*, and **Richard Bothner**, *St. Bonaventure University, Olean*



The Amphibians and Reptiles of New York State is the first guide to the amphibians and reptiles of New York State, a large and heavily populated state that hosts a surprisingly diverse and interesting community of amphibians and reptiles. This much needed guide to the identification, distribution, natural history and conservation of the amphibians and reptiles of New York State fills a long-empty niche.

This volume provides detailed narratives on the 69 species native to New York State. With a heavy emphasis on conservation biology, the book also includes chapters on threats, legal protections, habitat conservation guidelines, and conservation case studies.

Also included are 67 distribution maps and 62 pages of color photographs contributed by more than 30 photographers. As a field guide or a desk reference *The Amphibians and Reptiles of New York State* is indispensable for anyone interested in the vertebrate animals of the Northeast, as well as students, field researchers and natural resource professionals.

"The authors of this solid book combine a huge amount of experience and together probably have more expertise than those of any other state guide. I particularly enjoyed the sections on the history of herpetology studies in New York State and the nods to the urban herpetofauna of New York City. The book is explicitly oriented toward people who want to identify specimens they've encountered and learn more about the animals in their area."

—Russell Burke, Hofstra University

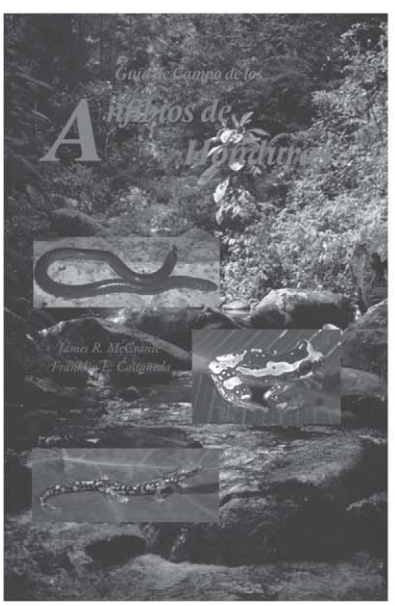
First Announcement

Current Research on Herpetofauna of the Sonoran Desert IV

April 11–13, 2008



Tucson, Arizona

The Tucson Herpetological Society (THS) and co-sponsors are pleased to announce the fourth meeting of *Current Research on Herpetofauna of the Sonoran Desert* (CRHSD). The first CRHSD meeting was held at The Phoenix Zoo April 9–10, 1999. This conference, co-sponsored by the Arizona Game and Fish Department, Arizona State University West, and The Phoenix Zoo, was hugely successful with a number of would-be registrants turned away due to seating limitations. Since then, this event has been held every 3 years and has grown in interest and enthusiasm. The second CRHSD meeting, sponsored by the THS and others, was held in April 2002 in Tucson, and the third meeting was hosted by ASU in Phoenix in April 2005.

The goals of this fourth meeting are two-fold: 1) dissemination of information concerning research on the herpetofauna of the Sonoran Desert (in the states of Arizona, Sonora, and on the Baja California peninsula and gulf islands); and 2) provide opportunities for social interaction and dialogue among meeting participants.

The meeting will begin on Friday evening with an Icebreaker Social Event. Scientific Sessions on Saturday and Sunday will include approximately 30–40 oral presentations as well as poster presentations. Saturday evening will include a Social Hour followed by a Banquet. There will be three invited speakers at the meeting. Harry W. Greene, Professor at Cornell University, will open the Scientific Session on Saturday morning. Cecil Schwalbe, of the U.S. Geological Survey, will be the Banquet speaker on Saturday evening, and Edward O. Moll, Professor Emeritus at Eastern Illinois University and Adjunct Professor at the University of Arizona, will be the featured speaker on Sunday morning.

The CRHSD IV second announcement will be made in the fall and will include registration information, call for papers, and information on accommodations at the Inn Suites Hotel. All information will soon be available on the THS web site (www.tucsonherpsociety.org). We hope you will mark your calendar and plan to attend what will be the continuation of an exciting and informative scientific meeting.

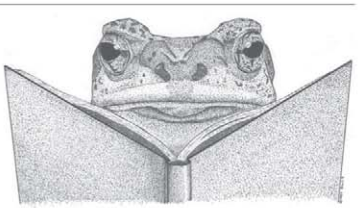
Guia de Campo de los

Anfibios de Honduras

James R. McCranie & Franklin Castañeda

This first Spanish edition of the *Amphibians of Honduras* is completely revised and updated with description of 124 species in 38 genera and 10 families. Taxonomic keys are provided in English and Spanish. The color plates include photographs of 121 species and 24 habitats. Eighty-five dot distribution maps cover the distribution of all 124 species. An additional 8 maps illustrate physical and political characteristics of Honduras.

Published with the financial support of the World Bank and RANA.



Specifications: 320 pages, 80 color plates, 6 x 9 inches. Hardcover (ISBN: 1-932871-11-1) $20.00. **Shipping:** $4.00 within the USA, $9.00 non-USA addresses.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution or Natural History notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order form will be sent prior to publication. These are also available upon request from the Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pdf/Adrates.pdf).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Central Michigan University, Department of Biology, 217 Brooks Hall, Mt. Pleasant, MI 48859, USA. Periodicals postage paid at Mt. Pleasant, MI 48859 and at additional mailing offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Breck Bartholomew, PO Box 58517, Salt Lake City, UT 84158, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Please notify Breck Bartholomew, SSAR Publications Secretary (contact information below), regarding missing or damaged issues.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 760		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 760	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2007 in the Society for the Study of Amphibians and Reptiles are as follows: **REGULAR** membership US$60 (Student $30)—includes *Journal of Herpetology* and *Herpetological Review*; **PLENARY** membership US$80 (Student $45)—includes *JH*, *HR*, and annual subscription to the *Catalogue of American Amphibians and Reptiles*; **INSTITUTIONAL SUBSCRIPTION** $125—includes JH and HR. Additional fee for airmail postage outside USA $35 for one year. Additional membership categories available on the SSAR webpage: http://www.ssarherps.org/pages/membership.html.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its newsjournal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Breck Bartholomew, SSAR Membership Office, P.O. Box 58517, Salt Lake City, Utah 84158, USA. Fax: (801) 453-0489; e-mail: ssar@herplit.com.

Future Annual Meetings

2007 — Saint Louis, Missouri, 11–16 July (with ASIH, HL)
2008 — Montreal, Canada (with ASIH, HL)
2009 — Portland, Oregon (with ASIH, HL)

About Our Cover: *Diporiphora winneckei*

Agamid lizards, popularly known as dragons, are strongly visually-cued. They have alert, upright postures, and most species seek elevated perches from which they adopt a sit-and-wait ambush style of prey capture.

The family is widespread throughout the Old World, from Australia and New Guinea to Asia, Africa, the Middle East, and southern Europe. Australia is home to 71 described species. The 14 species of *Diporiphora* make up Australia's second largest agamid genus. While dragons are distributed across the continent, with highest diversity in central and western deserts, *Diporiphora* is most numerous across northern Australia, particularly in semi-arid north-western tropical savannahs where the ground cover is dominated by spinifex (*Triodia* spp.).

Diporiphora are relatively poorly known. Little ecological work has been undertaken and the group is sorely in need of taxonomic review. The most recent systematic studies were in the 1970s and the most comprehensive of these dealt only with Western Australia and the Northern Territory (Storr 1974. Records of the Western Australian Museum 3[2]:121–146). Identification of species can be problematic and a number of unresolved taxa are known to occur in eastern Australia.

For the most part, *Diporiphora* species are outwardly similar in appearance, being relatively slender and small (maximum SVL for most species is 60–80 mm), lacking the elaborate spines, crests, and dewlaps that typify many agamids. Most are patterned with a pair of pale dorsal stripes overlaying a series of short dark cross-bands. This is ideal cryptic coloration for terrestrial to semi-arboreal dragons that dwell among grasses and low shrubs. Many dragons can accelerate to rapid, often bipedal sprints when pursued, but *Diporiphora* tend to be less swift, generally scuttling on all four limbs to the nearest cover.

The Canegrass Dragon (*Diporiphora winneckei*), depicted on our cover, is notable for its extremely slender, almost emaciated-looking build and the smooth, silky white ventral surface boldly striped with grey (males) or yellow (females). Breeding males develop a red flush on the flanks. *D. winneckei* has the broadest distribution of the genus, spanning the vast central and western sand-ridge deserts. Its habitat comprises interdunes and lower slopes vegetated with spinifex or canegrass (*Zygochloa*) and generally bare dune crests.

This *D. winneckei* is basking atop a hummock of spinifex, one of Australia's most herpetologically significant grasses. Wherever spinifex grows it supports a high diversity of lizard species including many endemics. When inactive or pursued, the lizard takes refuge within the matrix of slender, tough, needle-sharp spines.

D. winneckei is one of the most heat-tolerant Australian lizards, with specimens caught on the tops vegetation at midday having body temperatures of 42–46°C (Greer 1989. Biology and Evolution of Australian Lizards. Surrey Beatty & Sons, Sydney). This is above the lethal thermal limit for most species.

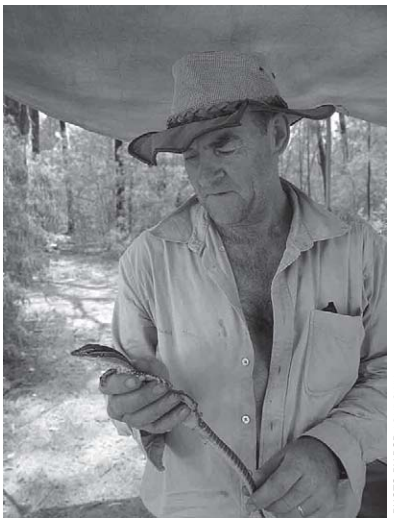

PHOTO BY BOB ASHDOWN

Our cover lizard was photographed by Australian herpetologist **Steve Wilson**, at Windorah in southwestern Queensland. Steve used Provia 100 ISO slide film and an Olympus OM2n camera with a 50mm macro lens, using natural daylight. Steve has written a number of field guides to reptiles of Australia and his home state of Queensland. His most recent book, a reptile book for children, is designed to instill a sense of wonder into the next generation. It was published in late 2006. His next project is a popular guide to the natural history of Australian lizards.

SSAR BUSINESS

Open Letter to Membership

SSAR will celebrate its 50th Anniversary in 2007. Special activities will take place during the Joint Meeting of Ichthyologists and Herpetologists (JMIH) in St. Louis, 11–16 July. The major events associated with SSAR's Anniversary are scheduled for 13 July. These events feature a symposium organized by Jonathan Losos entitled "Herpetology in the Age of Genomics." Jim Murphy and Kraig Adler will be the Masters of Ceremonies for a special SSAR Banquet that evening. The SSAR/HL auction will follow the banquet. And, of course, everyone is invited to attend the Business meeting on July 15. A link to registration on our website (http:www.ssarherps.org) will be available in January. Registration can be for the entire meeting or only for the day of the SSAR celebration.

—Roy McDiarmid, SSAR President
—Robin Andrews, SSAR Immediate Past President

NEWSNOTES

6th World Congress of Herpetology Call for Symposium Proposals

On behalf of the 6th World Congress of Herpetology Organizing Committee, we would like to invite colleagues to organize and propose symposia. Proposals should state clearly that the symposium organizer is ready to assume the organization of the symposium. Proposal submissions will be open until 30 September 2007 and should include the following items:

1) A symposium title; 2) The full name of the organizer or chair of the proposed symposium; 3) Institutional affiliation of the organizer and contacts (full address, e-mail, phone, and FAX numbers; 4) A brief text (200 words) explaining the goal of the symposium; 5) A list of potential speakers and their topics.

Presentations should be of 20 minutes duration for each participant (this time should include time for questions and discussions). If the Symposium organizer has compelling reasons for other time allotments, the symposium organizer must make his/her case with the Organizing Committee for an alternate scheme of time allotments that would allow for time coordination with the other symposia being held simultaneously.

Organizers should inform symposium participants to prepare their presentations in Power Point for PC.

Below are the names and contact of the members the Symposium Committee of the 6th World Congress of Herpetology; please send your proposal to one of the following:

Dr. Carlos Frederico D. Rocha (Head of Symposium Committee) (Rio de Janeiro, Brazil); e-mail: cfdrocha@uerj.br

Dr. Claudia Keller (Manaus, Brazil); e-mail: keller@inpa.gov.br

Dr Jean-Marc Hero (Queensland, Australia); e-mail: m.hero@griffith.edu.au

A New Book to Celebrate SSAR's 50th Anniversary

Contributions to the History of Herpetology

Volume 2 by Kraig Adler, John S. Applegarth, and Ronald Altig

From the reviews of volume 1, published in September 1989:

"Of absorbing interest." —Alwyne Wheeler (Archives of Natural History).

"Here is a portrait gallery that to browse will delay your next paper in progress!" —Joseph Ewan (Taxon).

"An important original contribution to the history of herpetology . . . exacting and exhaustive scholarship, and an unmistakable touch of class." —Hobart M. Smith (Herpetological Review).

This book consists of three sections, each worldwide in coverage. **The first and longest section, by Kraig Adler**, is a series of completely new biographies of the leading contributors to herpetology beginning with the author of the first book on the subject, Nicolò Leoniceno (1428–1524). The accounts have a portrait, signature, and references for further interest. These feature 285 herpetologists and also include information about their colleagues and students and many other persons. The comprehensive index encompasses volumes 1 and 2 and covers nearly 1,400 individuals.

Among the biographies included in volume 2 are these:

• Authorities on venomous snakes and antivenoms—Brazil, Calmette, Charas, Fayrer, Fontana, Mitchell, and Noguchi.

• Bartram, Bocourt, Cantor, Catesby, David, the Grandidiers, Pallas, Rüppell, the Sarasins, Swinhoe, and others who explored then-unknown continents.

• The classifiers, Blainville, Brongniart, Oppel, and Ray.

• Aldrovandi, Bogert, Brongersma, Dickerson, Lichtenstein, McCoy, Wettstein and others who built great museum collections.

• The anatomists, Gadow, Gegenbaur, Hyrtl, Lebedkina, Leydig, Rathke, Severino, Tyson, and Wiedersheim.

• The artistic team of Sowerby and Lear.

• Experts on diseases and cures, Elkan and Reichenbach-Klinke.

• Schmalhausen, Szarski, Williams, and other evolutionists.

• Popular writers, among them Behler, Bellairs, the Conants, Hopley, the Mintons, Oliver, Rose, Topsell, and Worrell.

Coverage is global: Africa (El-Toubi, FitzSimons, Power), Asia (Chang, Đào, Gasperetti, Gharpurey, Hoofien, Hora, Hu, Kirtisinghe, Makino, Namiye, Tweedie), Australia (Fry, Lucas, Macleay, Storr), Europe (Ahl, Boscá, Cherchi, Cott, Dely, Eiselt, Flower, Gmelin, Guibé, Guichenot, Hediger, Hellmich, Hillenius, Lataste, Mocquard, Morescalchi, Rasmussen, Špinar), North America (Auffenberg, Barton, the Brimleys, Burt, Cagle, De Kay, Estes, Gorham, Hallowell, Lowe, Mosauer, Neill, Perkins, Schwartz, Slevin, Strecker, Yarrow), and Central and South America (Álvarez del Toro, Carvalho, Freiberg, Gomes, the Iherings, Laurent, Orcés, Orejas Miranda, Picado, Rand, Vellard).

Also included are experts on taxonomic groups such as salamanders (Brame, Green, Rusconi, Twitty, the Wilders, Wolterstorff, Wurffbain), turtles (Caldesi, Hay, Schweigger, Wermuth), and snakes (Fukada, Mell, Saint Girons, Slowinski, Stull, Underwood). The book contains an additional 150 biographies.

The second section, by John S. Applegarth, is an index of 3,603 authors in taxonomic herpetology. This alphabetical list includes the full names, dates, countries of residence, and orders of taxa for everyone who has proposed a new taxon (genus or below, within the living families) or has had a taxon named in their honor. This is a unique resource for zoologists, historians, and librarians. In less than two decades (since the 1989 edition), the number of persons covered has increased by nearly 50 percent.

The third section, by Ronald Altig, is a listing of herpetologists giving the names of their doctoral university, their major professor, and the date of their degree. This extensive revision is three times longer than the 1989 edition. The information is arranged in such a manner that the academic lineages can be followed from generation to generation, both forward and backward in time. 3,810 names are included and fully indexed.

Specifications: 400 pages (8.5 × 11 inches or 21.5 × 28 cm), bound in library-grade cloth. Color frontispiece, 269 portraits. ISBN 978–0–916984–71–7. To be published July 2007. • **Regular Price:** $65. • **Special Price to SSAR Members** (if ordered *before November 2007*): $50. • **Shipping Costs:** USA address, add $4; non-USA add $9. • **Orders to:** SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158–0517, USA (*telephone and fax*: 801–562–2660; *e-mail*: ssar@herplit.com). • **Payment:** Make checks payable to "SSAR." Non-USA orders must be paid in USA funds using a check drawn on an American bank or by International Money Order. Books may be charged to American Express, Discover, MasterCard or VISA (please give account number and expiration date). • **SSAR Membership and Other Publications:** Membership information and a complete list of society publications can be obtained from the Publications Secretary at the address given above or at www.ssarherps.org.

Dr. Martin Whiting (Johannesburg, South Africa); e-mail: martin@gecko.wits.ac.za

Dr. Miguel Trefaut Rodrigues (São Paulo, Brazil); e-mail: mturodri@usp.br

Dr. Richard Griffiths (Kent, England); e-mail: R.A.Griffiths@kent.ac.uk

Herpetologists Honored for Contribution to Conservation

The Florida Chapter of The Wildlife Society (FLTWS) has announced the winners of the first annual Paul Moler Herpetological Conservation Award. The recipients, Mark Bailey, Kurt Buhlmann, Jeff Holmes, and Joe Mitchell, were selected for producing the new Partners for Amphibian and Reptile Conservation publication, "Habitat Management Guidelines for Amphibians and Reptiles of the Southeastern United States." Featuring detailed, yet easy-to-understand ideas and methods to help landowners improve the conservation value of their land, the book has received excellent reviews from land managers and conservation professionals across the region. The Guidelines effectively cover the wide variety of habitats and herpetofauna (amphibians, turtles, reptiles, and crocodilians) present in the southeastern United States, both with text and exquisite photography. The book is available to the public and can be ordered at http://www.parcplace.org/

The conservation award was presented during this year's annual meeting of the FLTWS, 11–13 April 2007, in St. Petersburg, Florida. The award was established in honor of one of Florida's preeminent herpetologists, Paul Moler, who retired in 2006 after 29 years of service with the Florida Fish and Wildlife Conservation Commission. "I am especially gratified to see this first Herpetological Conservation Award go to the authors of PARC's outstanding southeastern Habitat Management Guidelines," Moler said upon hearing the announcement. The FLTWS is made up of over 300 wildlife professionals dedicated to sustainable management of wildlife resources and their habitats in Florida. For more information on the society or this year's meeting, visit: http://www.fltws.org/.

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (rwh13@csufresno.edu) well in advance of the event.

20–23 June 2007—31st International Herpetological Symposium, Toronto, Canada. Information: http://www.kingsnake.com/ihs/.

11–16 July 2007—50th Annual Meeting, Society for the Study of Amphibians and Reptiles; 87th Annual Meeting, American Society of Ichthyologists and Herpetologists; 65th Annual Meeting, The Herpetologists' League. St. Louis, Missouri, USA. Information: http://www.dce.ksu.edu/jointmeeting/.

25–29 July 2007—5th Annual Symposium on Conservation Biology of Tortoises and Freshwater Turtles, Joint Annual Meeting of the IUCN Turtle Survival Alliance and the Tortoise and Freshwater Turtle Specialist Group. Atlanta, Georgia, USA. Information: http://www.turtlesurvival.org/.

3–6 August 2007—5th Conference on the Biology of Plethodontid Salamanders: Symposium in Honor of David B. Wake. Instituto de Biologia, UNAM and ECOSUR, San Cristobal de la Casas, Chiapas, México. Information: http://www.ibiologia.unam.mx/barra/congresos/salamandra/salamandra.html.

20–22 August 2007—Northeast Partners in Amphibian and Reptile Conservation (NEPARC) meeting, University of Virginia's Mountain Lake Biological Station. Meeting information, including registration and agenda are now available on the NEPARC website: www.pwrc.usgs.gov/neparc/Meetings/index.htm.

3–7 September 2007—Venom Week 2007. Tucson, Arizona, USA. Information: http://www.ocme.arizona.edu.

11–14 October 2007—29th Annual Meeting of the Gopher Tortoise Council, Milton, Florida, USA. Information: http://www.gophertortoisecouncil.org/.

2–4 November 2007—34th Annual Meeting, Kansas Herpetological Society, Topeka Zoo, Topeka, Kansas, USA. Information: http://www.cnah.org/khsAnnualMeetingInfo.html.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Michele Johnson** or **Josh Hale**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can be found at: http://www.herplit.com/contents.

Phylogenomics Of Reptiles

Our understanding of amniote genome evolution is based solely on chicken-mammal comparisons, but without large scale genomic data from phylogenetically intermediate taxa (i.e., nonavian reptiles) we cannot interpret the evolution of genome diversity in this group. Therefore, the authors used a BAC- (Bacterial Artificial Chromosome) and plasmid-end sequencing approach to characterize the genomes of three reptilian lineages: American Alligator (*Alligator mississippiensis*), Painted Turtle (*Chrysemys picta*), and Bahamian Green Anole (*Anolis smaragdinus*). The resulting data

show that, unlike the chicken, reptilian genomes are dominated by diverse, mammal-like transposable elements and simple sequence repeats (SSRs). Substantial differences exist among the reptilian genomes, as the *Anolis* genome displays higher SSR frequencies and lower GC content than the turtle and alligator genomes, which are characterized by distinctive CR1 (Chicken Repeat 1)-like long interspersed elements (LINEs) and fewer A-T rich SSRs. Additionally, all three reptiles have frequent tandem duplications that do not occur in chickens or mammals. The authors also found that DNA "words" evolve several orders of magnitude slower in reptiles than in mammals. They conclude that the ancestral amniote genome likely had a diversity of repetitive elements that were lost sequentially in reptilian and bird lineages.

SHEDLOCK, A. M., C. W. BOTKA, S. ZHAO, J. SHETTY, T. ZHANG, J. S. LIU, P. J. DESCHAVANNE, AND S. V. EDWARDS. 2007. Phylogenomics of nonavian reptiles and the structure of the ancestral anmiote genome. PNAS 104:2767–2772.

New Courtship Pheromone in Salamanders

Courtship pheromones are male chemical signals that affect female mating receptivity. Among vertebrates, these pheromones are known only in salamanders, and are most extensively studied in plethodontid salamanders. Courtship pheromones in plethodontids are delivered when a male brings his submandibular (mental) gland in contact with a female, transferring a multiprotein secretion from the gland. A single protein (PRF, plethodontid receptivity factor) from this secretion has been previously shown to increase female receptivity in *Plethodon shermani*, the Red-legged Salamander. In this study, the authors examined a second protein that, together with PRF, comprise 85% of the mental gland extract. They collected *P. shermani* adults from North Carolina, USA, removed the mental gland from males, and extracted the protein of interest from the gland secretions. In subsequent staged encounters between females and deglanded males (N = 32), females in 16 pairs were treated with the protein extract, and females in the other 16 pairs were treated with a saline control. While insemination success did not differ between the groups, treatment with the protein unexpectedly decreased female receptivity, as treatment prolonged the "persuasion" stage of courtship. The authors named this new pheromone, which acts in opposition to PRF, PMF (plethodontid modulating factor). They suggest that PMF may calm females, thereby facilitating the receptive effects of PRF, as the combined effect of both proteins increases female receptivity.

HOUCK, L. D., C. A. PALMER, R. A. WATTS, S. J. ARNOLD, P. W. FELDHOFF, AND R. C. FELDHOFF. 2007. A new vertebrate courtship pheromone, PMF, affects female receptivity in a terrestrial salamander. Animal Behaviour 73:315–320.

Snakes Sequester Toxic Compounds from Prey, Provision Offspring with Toxins

The Asian snake *Rhabdophis tigrinus* exhibits geographic variation in its use of nuchal glands in antipredatory behavior; in toad-free regions the snakes display the nuchal glands much less often than in regions where toads are potential prey items. The nuchal glands contain cardiotonic steroids called bufadienolides, which are major components of toad skin secretions. To determine whether variation in toad availability correlates with variation in bufadienolides in *R. tigrinus*, the authors compared the glandular fluid from snakes in toad-free (n=3), toad-rich (n=4), and toad-present (n=15) localities using proton NMR spectroscopy; as expected, snakes in regions where toads were available prey had higher toxin concentrations in their nuchal glands. The authors also conducted feeding experiments that confirmed that bufadienolides are sequestered from ingested toads.

Further, they found that offspring of dams from three mothers with no bufadienolides contained none of these toxins in their nuchal glands, while offspring of one dam with a high toxin concentration possessed bufadienolides immediately upon hatching, demonstrating that *R. tigrinus* can maternally provision their offspring with these defensive compounds.

HUTCHINSON, D. A., A. MORI, A. H. SAVITZKY, G. M. BURGHARDT, X. WU, J. MEINWALD, AND F. C. SCHROEDER. 2007. Dietary sequestration of defensive steroids in nuchal glands of the Asian snake *Rhabdophis tigrinus*. PNAS 104:2265–2270.

Sexual Size and Shape Dimorphism in *Podarcis* Lizards

Differing selective pressures acting on males and females can result in sexual dimorphisms (SD), but SD may decrease when similar species co-occur to decrease intersexual competition in the presence of interspecific competition. The authors investigated SD in two closely-related, ecologically similar lizard species, *Podarcis bocagei* and *P. carbonelli*, in northwestern Portugal in both allopatry (*P. bocagei*: 55 males, 48 females; *P. carbonelli*: 53 males, 46 females) and in sympatry (*P. bocagei*: 42 males, 24 females; *P. carbonelli*: 52 males, 44 females). For each adult specimen, they measured 10 biometric characters for use in multivariate (size) analyses and digitized 46 landmarks for geometric morphometric (shape) analyses. They found that males of both species are larger than females, and that females have longer trunks. Their results also showed that patterns of size SD were not modified in sympatry; the differences between males and females are consistent when the species co-occur, although there is some evidence for an increase in male head size for both species when in sympatry. Shape analyses further explored changes in head shape SD. These observations suggest that morphological differences between the two species are not due to interspecific competition in sympatry, but are likely the result of sexual and natural selection.

KALIONTZOPOULOU, A., M. A. CARRETERO, AND G. A. LLORENTE. 2007. Multivariate and geometric morphometrics in the analysis of sexual dimorphism variation in *Podarcis* lizards. Journal of Morphology 268:152–165.

Phylogeography of the California Newt

Divergence among lineages can be strongly influenced by geological change. In this study, the authors used mtDNA sequences and allozyme variation to examine genetic differentiation of the two subspecies of the California newt, *Taricha torosa*, in light of the geological history of the California coast and the Sierra Nevada mountains. They sampled 23 populations (198 individuals), from which they determined allozymic variation at 45 loci, and from 37 populations (62 individuals) they sequenced fragments of up to 778 bp of the cytochrome *b* gene. Standard phylogenetic analyses using either mtDNA or allozyme data supported the monophyly of *T. torosa* and of both subspecies [*T. t. torosa* (which occurs throughout coastal California and the southern Sierra Nevada) and *T. t. sierra* (which occurs in the central and northern Sierra Nevada)], and demonstrated geographic structure within these groups. Using a molecular clock, the authors estimated that the subspecies diverged from one another 7-13 Mya. To examine genetic differentiation at more shallow time depths, they used population genetic methods and inferred that the phylogeographic history of the species is complex, including allopatric divergence, isolation by distance, and range expansions. Although mtDNA and allozyme data for *T. t. torosa* were discordant at the boundary of the coastal-southern clades, they developed a biogeographic scenario that explains the different patterns of the two datasets. By using multiple genetic marker types, the authors were able to refine their phylogeographic interpretation for this species, and they encourage the use of multiple marker types in future work.

KUCHTA, S. R. AND A. TAN. 2006. Lineage diversification on an evolving landscape: phylogeography of the California newt, *Taricha torosa* (Caudata: Salamandridae). Biological Journal of the Linnean Society 89:213–239.

Rattlesnake Responses to Prolonged Starvation

Snakes can tolerate periods of starvation of two years or more, yet few studies of starvation physiology have examined reptiles or amphibians. To address this taxonomic gap, the author investigated the physiological and biochemical responses to prolonged starvation in *Crotalus atrox*, the Western Diamondback Rattlesnake, a species that occurs in environments that experience periods of severe food limitation. Sixteen wild-caught, subadult rattlesnakes were fed and acclimated in the laboratory and then assigned to one of four treatments (0, 56, 112, or 168 days of starvation). At the end of each treatment period, snakes were euthanized and analyzed for blood and tissue content. During fasting, snakes experienced decreased plasma glucose but increased ketone bodies, although with continued fasting ketone levels recovered to non-fasting levels. Relative body composition changed dramatically during starvation, with snakes relying mostly on lipid stores for fasting energetic demands. Further, fasting snakes appeared able to prevent essential fatty acids from oxidation, but essential and non-essential amino acids were used indiscriminately during starvation. Finally, the author suggests that changing excreted nitrogen profiles could be used to noninvasively monitor the nutritional status of natural populations.

MCCUE, M. D. 2007. Western diamondback rattlesnakes demonstrate physiological and biochemical strategies for tolerating prolonged starvation. Physiological and Biochemical Zoology 80:25–34.

Frog Phylogeny Informs Study of Island Colonization

Amphibians are thought to be poor dispersers, and as a salt-intolerant group, they are typically absent from oceanic islands that have never been connected to a mainland. Three volcanic islands in the Gulf of Guinea off the coast of West Africa, however, have seven endemic amphibian species (six frogs, one caecilian). To explore island endemism and colonization, the authors combined molecular genetic techniques with data on ocean currents and salinity and atmospheric circulation to explore the origins of the endemic frog *Ptychadena newtoni*. They sequenced the mitochondrial 16S rDNA gene from 30 specimens in the genus *Ptychadena*, and to increase resolution within the *P. mascareniensis* complex (of which *P. newtoni* is a member), fragments of cytochrome *b* and cytochrome oxidase subunit I genes were also sequenced from species in this complex. Using maximum likelihood techniques, *P. newtoni* was found to be a distinct species endemic to the island São Tomé, showing strong divergence from its closest relatives. This species is deeply nested within the *P. mascareniensis* clade. The authors propose that the most likely colonization mechanism for these frogs (and other endemics of the Gulf of Guinea islands) involved a synergy of rafting, favorable surface currents, and reduced surface salinity. They suggest that amphibian distributions may not be determined predominantly by vicariance, and that this common assumption should be reconsidered.

MEASEY, G. J., M. VENCES, R. C. DREWES, Y. CHIARI, M. MELO, AND B. BOURLES. 2007. Freshwater paths across the ocean: molecular phylogeny of the frog *Ptychadena newtoni* gives insights into amphibian colonization of oceanic islands. Journal of Biogeography 34:7–20.

Tuatara Body Condition Declines Over 50+ Years of Monitoring

Long-term monitoring is vitally important for conservation efforts, particularly for long-lived species such as the Tuatara (*Sphenodon punctatus*). Using a dataset that spans 54 years, the authors examined how long a Tuatara population must be monitored before significant long-term trends become evident. They calculated a body condition index [log(mass) versus log(snout-vent length)] for all adults marked on Stephens Island between 1949 and 2003 (1888 individuals). Results showed that body condition has substantially declined since 1949 for both sexes (although rainfall remained constant during the sampling period), but that a consistent pattern of decline is evident only after >22 years of data. To investigate seasonal trends in body condition, a separate morphological dataset was collected from 201 Stephens Island Tuatara in 2004–2005 during November, January, March, and May. They found that male body condition was significantly higher than that of females and that seasonal variation in body condition existed, but found no correlation of condition with monthly temperature or rainfall. The authors suggest that the long-term decline in body condition may be the result of a density dependent response to resource competition from increasing population size.

MOORE, J. A., J. M. HOARE, C. H. DAUGHERTY, AND N. J. NELSON. 2007. Waiting reveals waning weight: monitoring over 54 years shows a decline in body condition of a long-lived reptile (tuatara, *Sphenodon punctatus*). Biological Conservation 135:181–188.

Heterospecific Eavesdropping in Frogs

Many animal behaviors can provide "public" information to unintended recipients, information which may be useful for different kinds of audiences. Multi-species frog choruses provide an example of such a case: calls are typically interpreted as competition for mates within a species, but if calling behavior indicates the presence of predators, heterospecifics could also use information from the chorus regarding predation risk. The authors tested whether Panamanian túngara frogs (*Physalaemus pustulosus*) use heterospecific calls to assess predation risk by observing male frog responses to one of four treatments after exposure to conspecific calls and the appearance of a potential predator (N = 10 per treatment): silence, a conspecifc call, a heterospecific call of an allopatric congener (*P. enesefae*), or a heterospecific call of a sympatric frog species (*Leptodactylus labialis*). They predicted that if sympatric calls are an indication of predation risk, túngara frogs should respond to the stimuli in the following order of decreasing intensity: conspecific, *L. labialis*, *P. enesefae*, silence. Results showed that call rate and chuck frequency decreased in this order, while call latency (time after stimulus before calling resumed) increased in this order, supporting their prediction and demonstrating that túngara frogs can distinguish between informative and uninformative heterospecific calls. The authors suggest that participating in mixed-species choruses may allow males to reduce their predation risk without increasing mate competition. These choruses also provide an opportunity to further study emergent group behavior.

PHELPS, S. M., A. S. RAND, AND M. J. RYAN. 2007. The mixed-species chorus as public information: túngara frogs eavesdrop on a heterospecific. Behavioral Ecology 18:108–114.

Thermoregulatory Mechanism in Reptiles

To effectively thermoregulate, ectothermic animals must be able to sense both environmental and internal temperatures. Although thermoregulatory behavior is vitally important for maintaining cellular functions, the mechanisms that allow heat sensing are unknown. Recently, heat-sensitive transient receptor potential ion channels (TRPs) were discovered in *Drosophila* and mammals, and they may be suitable temperature sensors in reptiles as well. The authors demonstrated the presence of TRPs in reptiles and tested the hypothesis that TRP genes control reptilian thermoregulation. They sequenced a region of the heat sensing TRPV1 gene from three reptilian species [a crocodile (*Crocodylus porosus*), a skink (*Pseudemoia entrecasteauxii*), and an agamid (*Amphibolurus muricatus*)] and combined this data with existing sequence data to find that the reptilian TRPV1 sequences have a unique insertion of two amino acids, forming a well-supported clade sister to mammalian TRPV1. Using real-time PCR, they determined that TRPV1 and TRPM8 are expressed in heart, liver, and surface muscle tissues in the crocodile, and therefore have the potential to sense both internal and external temperatures. Inhibiting these genes in crocodiles (N = 7) led to dramatically altered thermoregulatory behavior, as the animals stopped their typical shuttling between basking and diving in cooler water. These results describe the proximate mechanism for temperature sensing in reptiles.

Hymen Marx. Formal portrait taken in 1978. Courtesy of the Field Museum of Natural History (Neg. No. GN82890).

Hymen Marx, Curator Emeritus at the Field Museum of Natural History in Chicago, Illinois, died on 25 January 2007 in Sun City, Arizona. During his 42 years at the Field Museum, Hy contributed much to the field of herpetology through his own research and through his unique, lively, and supportive personality.

Hymen "Hy" Marx, was born 27 June 1925, in Chicago, Illinois. He lived in the Chicago area until his move to Arizona in the early 1990's. His father, Phillip Marx, was a butcher and his mother, Minnie Serota Marx, was a homemaker. Hy had one sister, Molly, born 17 October 1921. Hy was drafted into the U.S. Air Force in 1943. He served as a radar mechanic and was stationed in the UK where he worked on a ground crew of the 8th Air Force maintaining the radar systems of the famous "Flying Fortresses." Like so many others, Hy went back to school in 1945 under the G.I. Bill and graduated in 1949 from Roosevelt University with a B.S. degree and a major in biology. That marked the end of Hy's formal education, and from then on he depended on his colleagues and his own intellectual curiosity to fuel his career development. In Hy's case and to his great credit, that was enough. While in school, Hy met Audrey Elaine Greene and they married in 1950. Hy and Audrey had two children, Michael Phillip Marx and Nancy Lynn Marx Ruesch. Nancy and her husband, David, now have three lovely teenage daughters, Melissa, Stephanie and Devyn who fondly remember their grandpa.

In 1948, while he was a student at Roosevelt University, Hy began volunteering in the Division of Amphibians and Reptiles, working as an assistant to Karl P. Schmidt. Hy referred to Clifford H. Pope and "K. P." Schmidt as his "academic papas." Hy joined the Division in 1950 as its first full-time assistant. For the next ten years, he served as "Collection Manager" and managed the collection through significant growth and reorganization including a major move from the third floor to the ground floor in 1952–53. This period of intensive collection growth was marked by the arrival, in 1954, of 35 five-gallon milk cans containing 77,000 frogs and toads that were sent by the Institut des Parcs Nationaux de Congo Belge to Karl Schmidt for identification. This huge shipment almost matched the number of specimens (85,000) in the entire collection at the time and a significant number of these specimens were deposited at the Field (Bauer 1954). This period was also marked by the Division's single most significant purchase, that of the Edward Harrison Taylor collection of 35,000 specimens, which was accessioned beginning in 1959. That collection, which is extensively cited in the herpetological literature, includes many type specimens, caecilians and skeletons. Its geographic strengths include Mexico, Costa Rica, Liberia, Sri Lanka, and Thailand. During these ten years, Hy also published 16 papers which led to his promotion to the curatorial ranks. He was promoted to full curator in 1973.

For roughly 40 years, Hy's career at Field Museum overlapped with that of Robert (Bob) F. Inger. Hy and Bob collaborated on several publications but the most notable was their monograph on the snakes of the colubrid genus *Calamaria* (Inger and Marx 1965). This monograph embraced many of the newest methods and approaches of that time and it remains a landmark work on this group of snakes today.

In addition, Marx's research interests also included the herpetofauna of Egypt, the systematics and zoogeography of the vipers, the phyletics of morphological characters, the application of phyletic character analysis to convergent snake species, and the application of Sharrock and Felsenstein's combinatorial method to phylogenetic studies. To facilitate his NSF supported collaborative research with George Rabb, over 500 snake skulls were removed from preserved specimens and prepared for character analysis studies. These skulls, comprising over 235 genera, form a subset of the osteology collection that is well used by researchers. This work resulted in their "50 characters volume" (Marx and Rabb 1972) that is still of great practical use to students of the biology and systematics of squamates.

Following this time, one of us (HKV), had the privilege of collaborating with George Rabb and Hy on a project involving character analysis (Marx et al. 1977). During the two years that we worked on this project the three of us had many stimulating and heated discussions. Those readers who knew Hy will understand us when we say that Hy provided us with plenty of aggravation and entertainment. He often referred to his two co-workers, not as his esteemed collaborators, but rather as his "close enemies."

Hy's research interests were varied but the subject that interested him most was the evolution of the venomous snakes of the family Viperidae. But Hy did not fit any stereotype of a dusty, dry museum curator—if you met Hy, even briefly, you immediately learned that he was exceptionally gregarious! This was true in both his personal and professional life. In his professional life, this took the form that most of us call collaborations, but Hy referred to it as "sharing our sandbox." He was fun to collaborate with but this activity was not for the weak of heart! He was sharp, witty, insightful, and prone to wander far off the subject. It was entirely

Federico Medem and Hymen Marx (right) examining South American crocodile skulls at the Field Museum in 1954. Courtesy of the Field Museum of Natural History (Neg. No. Z86441).

possible to begin with a lively discussion of the shape of the dentary bone in the Gaboon Viper, *Bitis gabonica*, and then find yourself listening to Hy giving you a review of "Sleeper," Woody Allen's latest movie at the time. This was vintage Hy Marx. No collaborator could expect to not be a victim at some point of one of Hy's practical jokes. That was the cost of doing business. Karel Liem, Henry Bryant Bigelow Professor of Ichthyology at Harvard University and George Rabb, now President Emeritus of the Chicago Zoological Society, and several others know this only too well!

Hy contributed greatly to the academic and administrative life at Field Museum. He served as the Head of the Division of Amphibians and Reptiles from 1970–79 and from 1985–1990, and over the years he served on more than 20 Museum committees. Hy fully understood the importance of encouraging young people in their interests and for that reason, he was an active contributor to Members' Nights at the Museum when it opens its doors for members to view the work that goes on "behind the scenes." Hy also had many unofficial roles at the Museum and he served as a sort of social guru to staff throughout the Museum. In this regard, Hy referred to himself as a "social butterfly" and enjoyed organizing both intellectual discussions on character analysis as well as recruiting teams and scheduling times for doubles tennis matches.

During Hy's four decades of service at Field Museum he also served on the Committee on Evolutionary Biology at the University of Chicago. In this capacity, he did not teach formal classes but rather he informally guided both master's and doctoral degree students in their research programs. On this, one of us (HKV) can speak from first hand experience. Hy helped me choose a Ph.D. research topic on sea snakes that has shaped my entire professional career. He freely gave his time and expertise to help many young visiting scientists prosper in their special fields of study. One of the "official" activities of visiting researchers and students was to visit Hy's office and kibitz about their research. For this we are all very grateful to him!

Hy was not a man to try to impress others by putting on airs of self-importance. No, he was equally friendly to the Museum's housekeeping staff and the top administrators of the Field Museum and other lofty institutions. He was not impressed with administrative rank and academic credentials and he applied uniquely Marxian methods to make this evident, as, for example, in his assignment of nicknames. No one received much respect and no one could hide!! For example, Robert K. Johnson, Chairman of the Zoology Department, was "Bunky" or "El Bunko Grande," James P. Bacon, Curator of Reptiles, San Diego Zoo, was "Bakey," and George Rabb, Director of the Brookfield Zoo, was "Georgy Porgy." Of course, behind each of these nicknames was an endearing story that showed how Hy paid attention to the human beings that he lived and worked with. We were individual people, not Directors, Curators, and Chairmen. In the end, that is why so many at the Field Museum and in the field of herpetology counted Hy Marx as a close friend, a great colleague, and a real human being. Hy Marx was truly one of a kind, absolutely unique, an amazing rare bird, and irreplaceable. All of our lives have been immensely enriched by knowing Hy Marx and we will miss him greatly.

Hy Marx, Impish Innovator

I first met Hy in 1972, during a visit the Field Museum to examine preserved coral snakes for my thesis research. Over the ensuing decades I came to know him as a friend and important, if under appreciated, player in the late twentieth century rise of snake biology. Hy was a committed curator, obsessed with facilitating the use and long-term welfare of museum specimens, as well as a shrewd, smart, and decent man. He was also insatiably curious about everything and everyone, and often extraordinarily funny.

We became friends at a time when research on snakes, which had figured in some of Hy's first publications, was reaching critical mass. By the early 1970's Henry Fitch's Kansas natural history monographs were stacking up and Rick Shine had begun doctoral studies of Australian snake natural history; Carl Gans was churning out papers on reptilian functional morphology and Gor-

don Burghardt's first publications were revealing the rich texture of snake behavior. By the early 1980s the Hennigian revolution in systematics had inspired a paradigm shift in evolutionary studies, from largely hand-waving about such topics as adaptive novelties and historical effects on community structure to the now-routine use of explicit analytic frameworks. Fulfilling the promise of historical evolutionary approaches to snake ecology requires phylogenetics, and beginning in 1965, thanks to a pioneering collaboration, we got it in spades.

With George B. Rabb and Karl F. Liem, Hy wrote a series of papers that set the stage for the integrative studies of snake biology that have flourished over the past three decades. It began when George called him out to Brookfield Zoo to see a live *Eristicophis*, and their attempts to better understand that strange creature led to an exceptionally interesting paper on the evolution and biogeography of viperines. Next they teamed up with Karl F. Liem for an anatomical study of the enigmatic "pitless pitviper," *Azemiops feae*, known then from 11 specimens, one of which Hy found in a large jar of uncatalogued frogs in his own collection! A truly ambitious survey by Marx and Rabb of 50 characters in 500 snakes appeared in 1972, followed by several more synthetic papers in *Evolution* and other prestigious journals.

Hy was short in stature and big in personality. My visits to the Field Museum typically encompassed several predictable stages. Upon arrival I'd be summoned to his office, whereupon he'd demand to know why I was there (regardless of the appropriate letter I'd always sent in advance, inevitably in plain sight on his desk), then launch into a merciless combo of inquiry and gossip. I'd catch my breath, tease Hy about his "ridiculous comb-over," and ask about the latest phylogeny for colubroids; he'd harangue me about the palatine teeth of *Pythonodipsas* and brag about some rare taxon he'd secured from a foreign colleague, all of it punctuated with "Hey putz, now watch this!" and "You're outta your mind!" After a half hour or so he'd unroll the latest computer output, swear me to secrecy, and after a spirited discussion admonish me to quit loafing and get to work. Once on a particularly hot summer's day I encountered Hy in his office, shirtless and watering several large potted plants. After growling a rude nickname and giving me a hug, he propped back in a chair, clasped his hands behind his head with a big grin, and said "Come on in, the water's fine!" The guy made his mark and we miss him.

—Harry W. Greene, Department of Ecology and Evolutionary Biology, Cornell University

Hymen Marx: in Tribute to a Loveable Rascal

Hy Marx was a truly unique person—in more ways than one. Always the practical joker and goof-off, he did have a serious streak**,** but it was well hidden. Hy enjoyed life and his carefree attitude was refreshing. He had a genuinely charming smile with a glint in his eyes, rather like a leprechaun. He also was one screw loose from being a nutcake, but that didn't bother him in the least; he reveled in being wacky and crazy. Hy had a different perspective on life than most people and he just had a good time in whatever he did. He poked fun at everyone, regardless of rank or importance, including himself as often as not. Hy had three passions that I know of: viperid snakes, Gilbert & Sullivan, and tennis.

Upon his retirement, I referred to him as the "fourth, funniest, and ever-youngest of the Marx brothers." And I pointed out that he paradoxically combined "the traits of a ruthless, savage killer (as on the tennis court where he showed no mercy) with those of a wonderfully likable and charming fellow with a heart of gold." I also pointed out that when he retired the museum could put him on exhibit and charge special admission if they wanted to increase their revenue.

The summer I spent at the Field Museum on a Dee Fellowship I was privileged to be able to sleep in the Division's lab. Hy was the first person I saw each morning. I had convinced him that his back needed adjustment. One morning after I adjusted him, he fell on the floor, screaming and clutching his lower back as if in great pain, "You broke my back!" Then he jumped up and started laughing like crazy—he really had me fooled. Another time he came into the museum limping, holding one leg an inch shorter than the other—again blaming it on me.

Hy was a man of few words when it came to answering correspondence. My first letter from him consisted of two lines with the salutation and signature twice as long as the letter; the next letter was three lines long. I discovered early on that the easiest way to get information out of Hy regarding FMNH holdings was to mail a pre-addressed and stamped postcard with the questions written out, leaving blank spaces for him to fill in. And presto! Back came the awaited answers in the filled in spaces.

Hy made it clear from the beginning that he refused to take the time to look at, read, or critique any of my manuscripts. He only liked to see the final publication! But I got even with him once. Because of my fondness for Hy, I dedicated my first snake species after him, a Philippine blind snake (*Typhlops marxi*). I hoped to keep this hidden from him and have it be a surprise upon publication. However, due to several problems, I was forced to send Hy a draft of the paper for his review. The cat was out of the bag and he was forced to help me with the manuscript, which he actually did. He began his letter with "I am pleased to hear from you and your written lunacy" and ended it with "Flattery will get you everywhere."

When I presented Hy with a list of rare snakes that I wanted to dissect for my project he went hysterical with lamentations and anguish at the thought of me opening up his precious (and often unique) specimens. Every rare snake I wanted to look at was like an act of pulling teeth. He even swore to track me down and kill me if I didn't publish the acquired data within five years.

There is no doubt that Hy Marx is dearly missed by everyone who knew him. His playful good humor dispensed so freely during his life continues in the smiles that cheer us in remembering him. He was certainly one in a million!

—Van Wallach, Museum of Comparative Zoology, Harvard University

ZOO VIEW

Three New Books

AMERICAN ZOOS AND AQUARIUMS HAVE BEEN, AND REMAIN, ENMESHED IN THE POLITICAL SYSTEM IN WHICH THEY RESIDE. JUST LIKE THE MENAGERIES OF THE PAST, ZOOS TODAY ARE SHAPED BY POLITICS. INSTEAD OF MONARCHS CEMENTING POLITICAL ALLIANCES OR DEMONSTRATING THEIR MILITARY POWER BY CONTROLLING ANIMAL COLLECTIONS, WE NOW HAVE INTEREST GROUPS, ATTORNEYS, CITY COUNCILS, CONGRESSMEN, BUREAUCRATS, AND CITIZENS DEBATING THE EXHIBITION OF ANIMALS. AT THE MOST FUNDAMENTAL LEVEL, THE STRUGGLES AT ZOOS AND AQUARIUMS ARE OVER WHO GETS TO CONTROL THE FATES OF THE ANIMALS. IN THE MICROCOSM OF THE ZOO WE SEE INTEREST GROUP POLITICS PLAYED OUT AS VARIOUS ORGANIZATIONS STRUGGLE TO TRANSLATE THE WISHES OF THEIR CONSTITUENTS INTO A COHERENT POSITION ON THE PUBLIC DISPLAY OF ANIMALS. THE CHANGING ANIMAL ENCLOSURES FREQUENTLY NOTICED BY THE VISITORS, SUCH AS ELABORATE NEW IMMERSION EXHIBITS, MASK MUCH DEEPER POLITICAL CHANGES THAT HAVE HAPPENED WITHIN ZOOLOGICAL PARKS AND AQUARIUMS IN THE UNITED STATES. IT IS QUESTIONABLE, FOR EXAMPLE, WHETHER THE VERY ANIMALS EXHIBITED IN ZOOS TODAY WOULD HAVE BEEN THERE WITHOUT THE POLITICAL PROTECTION AFFORDED BY THE AZA.

— JESSE DONAHUE AND ERIK TRUMP

The American Association of Zoological Parks and Aquariums (AAZPA) was founded in 1924. Seventy years later, the name was changed to the American Zoo and Aquarium Association (AZA). Some of the organizational purposes of AZA are (1) to promote discussions and cooperation among zoo and aquarium professionals; (2) to set high standards for its accredited member institutions, now over 200; (3) and to support *in situ* and *ex situ* conservation initiatives.

In their book, *The Politics of Zoos. Exotic Animals and Their Protectors* (Northern Illinois University Press, DeKalb, Illinois, 2006; ISBN-0-87580-364-4 [cloth]; ISBN-0-87580-613-9 [paperback]), Jesse Donahue and Erik Trump describe the political environment surrounding zoos and aquariums from the 1960s to the present and the role of AZA and its leaders in interacting with federal regulatory agencies, animal rights activists, and other interested parties. This is a particularly relevant book for me as a zoo professional. My career started in the mid-1960s and I watched firsthand as zoo workers tried to address new challenges in the face of criticism on many fronts as described in this useful history. The book elaborates on the sad reality that many of us are concerned but traumatized by the enormity of the problem of disappearing biodiversity. We continue to struggle to find suitable niches, both within our institutions and in the broader conservation and academic community. If we are able to do so more effectively, the final beneficiaries will be the plants and animals entrusted to our care. I recommend this book without reservation.

David Barker and I worked together at the Dallas Zoo for many years. During our time together, he began to take courses in photography at one of the local colleges. It was clear from the beginning that Dave had a superb artist's eye and special skill for photographing herps. In my view, his images are some of the finest ever put on film. If you doubt my statement, pick up a copy of *Pythons of the World, Volume II. Ball Pythons. The History, Natural History, Care and Breeding* (VPI Library, Boerne TX, 2006; ISBN: 0-9785411-0-3), produced by Dave and his wife Tracy Barker. This book is the most impressive treatment of a single python species ever produced. Although ball pythons have become a mainstay in the herpetocultural trade, I had no idea that they came in so many color morphs, often affixed with a colorful name such as "Jester," "Jaguar," "Killer-bee," "Dreamsicle," "Phantom-lesser-lucy," "Wanna-bee," "Fireball," "Ghost/Pastel," "Sandblast," "Scratchoff," "Zipper," and "Dirty-Joe," to name but a few of the 200 or so identified color phases. Many of these variations are beautifully pictured. The Barker book is much more than a handsome coffee-table tome, for it is filled with information on snake biology, natural history, and suggestions for captive maintenance. The book is a useful primer chock-full of recommendations for keeping captive snakes of other species as well. The book is of the highest quality—beautifully bound, first-class paper quality, and even the shipping box is impressive. No pythonophile should even consider living without this book in hand. A review of this book was published recently by Michael Burger (2007. Herpetol. Rev. 38:118–119). Notably, the book has just been named "Best Animal Book of 2006" by the Independent Publishers Awards.

The San Diego Zoo has a long history of publishing herpetological observations. Laurence M. Klauber was the first curator of reptiles in the 1920s, consulting curator beginning in 1931, and served on the Board of Trustees from 1943 to 1968 (Fig. 1). Between 1931 and 1955, C. B. "Si" Perkins was the head of the reptile collection and was in charge of the project to build a new reptile house, which stands to this day (Figs. 2, 3). When Klauber wrote *Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind*, he referred to "Si" and Charles E. Shaw, his curatorial successor, repeatedly in his opus as many behavioral observations in that book were made at the Zoo with these two men. Klauber named the leaf-nosed snake, *Phyllorhynchus decurtatus perkinsi*, after Perkins. In turn, Perkins published several compilations in *Copeia* on longevity of amphibians and reptiles in cap-

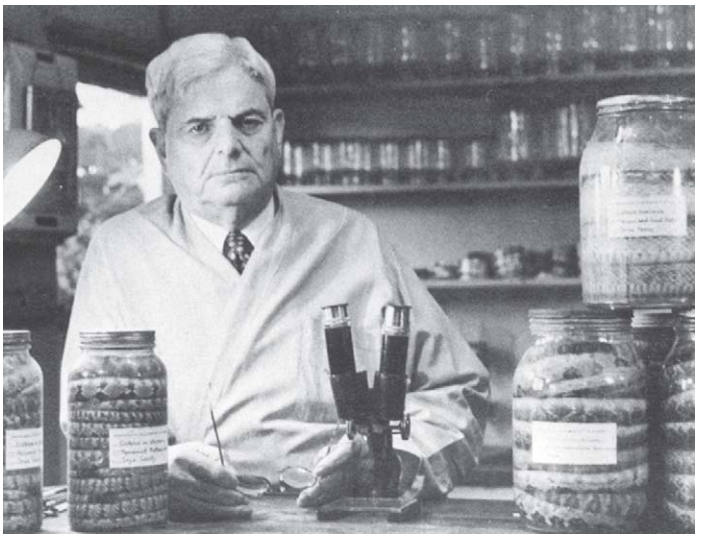

FIG.1. Laurence M. Klauber. Photograph provided by Kraig Adler.

FIG. 2. C. B. "Si" Perkins (right). Credit: San Diego Zoological Society Archives.

tivity, notes on captive-bred snakes, incubation and hatching of snake eggs, frequency of shedding in injured snakes, and hybrid rattlesnakes.

Shaw published papers on chuckwallas, eggs and young of some African, United States, and Mexican lizards and other reptiles, longevity of snakes in North American collections, and husbandry of sea snakes (Fig. 4). Based on observations at the Zoo, he documented reproduction in the Cuban and Rhinoceros Iguanas, and Galápagos Tortoise. His studies on the male combat "dance" of some crotaline snakes, American colubrid snakes, and additional remarks on combat in other colubrid and elapid snakes serve as classic behavioral reports. He wrote many articles in the zoo publication *ZOONOOZ*. In 1974, Shaw and Sheldon Campbell, a Zoo board member and later president, published the book *Snakes of the American West*.

Some 80 years after Klauber began his stint at the Zoo, Jeffrey M. Lemm from San Diego Zoo's Conservation and Research for Endangered Species (CRES) carries on the strong tradition in herpetology with his new book, *Field Guide to Amphibians and Reptiles of the San Diego Region* (University of California Press, Berkeley and Los Angeles, 2006; ISBN-13: 978-0-24573 [cloth]; ISBN-13-0-520-24574 [paperback]; 326 pp., 197 color photographs; 72 range maps; taxonomic key by Jay Savage). In the Preface, Lemm acknowledges the contributions of Klauber, Perkins,

FIG. 3. Photograph taken in 1935 of C. B. Perkins (left) with Sheldon Campbell (middle) and Charles Shaw (right) holding several snakes. Credit: San Diego Zoological Society Archives.

and Shaw. His book is filled with useful information about geology and climate, geologic history, major habitats, animal diversity, problems and conservation, species accounts, amphibian chytridiomycosis, snakebite and venom, and glossary. This field guide deserves a place on the bookshelf.

Lemm identifies two anuran taxa of special concern: Califor-

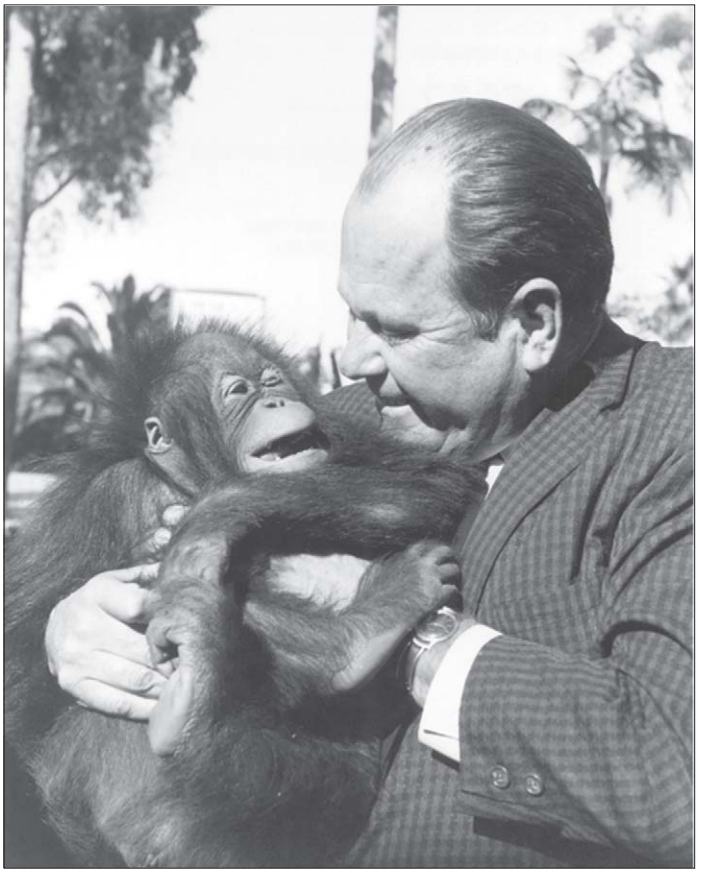

FIG. 4. Charles E. Shaw and "Maggie" in 1964. Credit: San Diego Zoological Society Archives.

nia Red-Legged Frogs (*Rana draytonii*) which have probably been extirpated in San Diego County, and the seriously endangered California Arroyo Toad (*Bufo californicus*). In the following article, zoo personnel at the Santa Barbara Zoo have developed a multi-faceted initiative of field surveys and educational programs to address the plight of these amphibians.

There are more than 200 accredited members of the Association of Zoos and Aquariums (AZA) dedicated to wildlife conservation through education and research. In fact, participating in field research has become an important activity of accredited zoos and aquariums (e.g., see Herrmann and Herrmann 2002; Zippel 2002). The Santa Barbara Zoo (the Zoo) is a comparatively young zoo that opened in 1963 and was first accredited by the AZA in 1981. The Zoo is dedicated to the preservation, conservation, and enhancement of the natural world and its living treasures through education, research, and recreation.

Beautifully situated on 30 acres of land in Santa Barbara, California, the Zoo overlooks the Pacific Ocean out to the Channel Islands to the south and the chaparral-covered slopes of the Santa Ynez Mountains to the north. Although the Zoo has a modest animal collection of about 600 specimens, we play an active and important role in field research, collaborating with various agencies on several conservation projects with one devoted to native amphibian conservation. Through a partnership between the Zoo and the United States Forest Service (USFS), Zoo staff currently survey streams in the Los Padres National Forest (LPNF) for California Red-legged Frog (*Rana draytonii*) and Arroyo Toad (*Bufo californicus*) egg masses and larvae. Both *R. draytonii* and *B. californicus* inhabit portions of LPNF in Santa Barbara County, California and are of critical conservation concern.

Prior to Bullfrog (*Rana catesbeiana*) introduction (Storer 1922), *R. draytonii* was the most abundant (Jennings and Hayes 1994) and largest (Storer 1925) of the ranid frogs occurring on the west coast. *Rana draytonii* has disappeared from approximately 75% of its known historical range and is listed as a federally threatened species (USFWS 1996). Habitat loss, exotic predators, off-road vehicle use, and dam and reservoir construction currently threaten *R. draytonii* populations. Although higher numbers of *R. draytonii* occur between Marin County and Santa Barbara (Jennings and Hayes 1994), an area that includes our study sites (Upper and Middle Santa Ynez in LPNF), these populations are still threatened by introduced predators, particularly Bullfrogs (Moyle 1973) and Mosquitofish (Hayes and Jennings 1986).

Bufo californicus has disappeared from 76% of its known historical range (Jennings and Hayes 1994) and in 1994 was listed as a federally endangered species (USFWS 1994). Being that the primary cause for declining *B. californicus* numbers is habitat loss, management recommendations for this species include greater habitat protection, and some recreational areas of LPNF are closed to visitors during the *B. californicus* breeding season (V. Hubbartt, pers. comm.). Exotic predators, however, still negatively affect the aquatic life stages of both *R. draytonii* (Jennings and Hayes

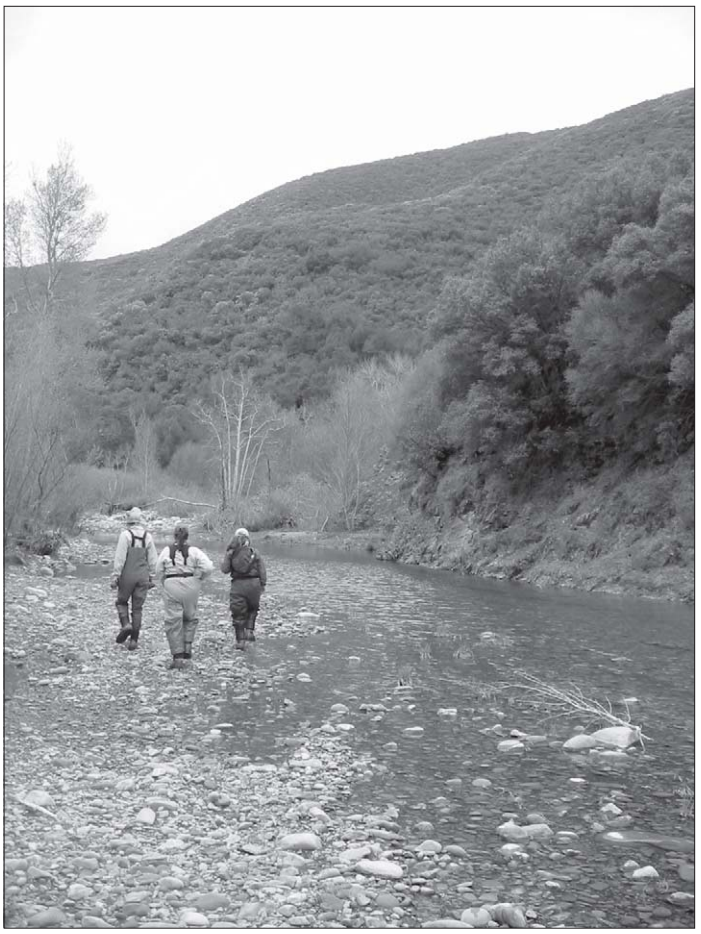

FIG. 1. A stream in the Santa Ynez River Valley, Santa Barbara County, California used as breeding grounds by California Red-legged Frogs (*Rana draytonii*) and Arroyo Toads (*Bufo californicus*).

FIG. 2. A California Red-legged Frog egg mass.

FIG. 3. C. Drew Foster and Estelle Sandhaus place an exclosure around a California Red-legged Frog egg mass in the Upper Santa Ynez Valley, Santa Barbara County, California.

1994; Kiesecker and Blaustein 1997; Lawler et al. 1999) and *B. californicus* (Jennings and Hayes 1994; Sweet 1993).

Because both anuran species are more vulnerable during their aquatic stages (e.g., to aquatic predators, chemicals from runoff, rising waters, etc.), the Zoo, in cooperation with the USFS, is examining population numbers in this phase and attempting to reduce larval predation by exotic aquatic predators. In suitable breeding areas, transects are established and regularly monitored during the breeding season. When egg masses are located, we quantify the developmental stage of the eggs and record the date, time, water depth, geographic coordinates (to allow for future monitoring of individual egg masses), and water and air temperature. Additionally, exclosures constructed of metal mesh formed into a cone shape are placed around egg masses to prevent aquatic predators from consuming them. This practice appears to be effective (we have observed egg masses placed in exclosures undergoing complete development), but will be evaluated further beginning in Spring 2007. We will also further examine the role of exotic aquatic predators.

In addition to playing an active role in *B. californicus* and *R. draytonii* conservation through research, the Zoo is promoting native herpetofaunal conservation through public education. Because of the Zoo's close proximity to LPNF, frequent day trips to the sites can be accommodated, and fieldwork participants can disseminate the conservation message to Zoo visitors through keeper talks and presentations. Additionally, the Education and Guest Services Departments are able to convey these messages on signage throughout the Zoo and newsletters that reach over 15,000 households per mailing. The Zoo also has an agreement with the USFS to create an exhibit featuring native reptiles and amphibians of LPNF. This exhibit will be part of a themed area of the Zoo dedicated to celebrating and promoting stewardship of our local wildlife. We estimate that as many as 450,000 visitors annually will learn about local herpetofaunal conservation by attending this exhibit. Communication is an essential component in raising community awareness of local conservation needs, and the Zoo's role as a center of conservation, education, research, and recreation affords us a unique opportunity to reach a large number of individuals.

Acknowledgments.—We are extremely grateful for the opportunity to participate in *Bufo californicus* and *Rana draytonii* conservation efforts, and wish to thank Richard Block (CEO/Zoo Director), Nancy McToldridge (Chief Operating Officer), and Sheri Horiszny (Assistant Director of Animal Programs), all of the Santa Barbara Zoo, Valerie Hubbartt (Resource Assistant/Wildlife Biologist) of the LPNF Santa Barbara Ranger District, and Jamie Uyehara (Specialist for SoCal Listed Species) of the LPNF Supervisor's Office for these opportunities.

Standard Language (Insert Language of Choice) Names Versus Common Names

BRIAN I. CROTHER
Department of Biology, Southeastern Louisiana University
Hammond, Louisiana 70402, USA
e-mail: bcrother@selu.edu

Caramaschi et al. (2005) recently published an excellent paper on providing "common" names to species of frogs in the genus *Leptodactylus*. They are to be commended for this and for their logic on why it is important to devise these names. Their criteria for determining these names are models to be followed.

However, I have a single comment that I hope will be informative and useful. In the North American amphibian and reptile names publications (Crother et al. 2000, 2003), notice that we never use "common name" and it is for specific reasons. First, what is common about them? These are unique appellations that are simply non-binomial and non-Linnaean. In the North American list they are called Standard English names. We did not presume to tell Spanish or German or Chinese, etc. what they should call the taxa in their language. Caramaschi et al. gave a beautiful example when they translated from the Portuguese or Spanish to an English name. They made a Standard English name, not a common name. They also make Standard Spanish and Standard Portuguese names and this should be wholeheartedly applauded and supported. These are not Spanish or Portuguese common names in any sense. I hope workers providing non-binomial non-Linnaean species names will consider that these are not common names, but Standard Language names.

It is important to provide these names, I just hope we can agree that they are not common.

Effects of Toe-Clipping on the Survival and Growth of *Hyla squirella*

Toe-clipping is a widely used and cost-effective method for marking amphibians for ecological studies, but recent research has suggested that toe-clipping may cause adverse impacts on amphibian health and behavior. Several studies have documented decreased growth or recapture rates in toe-clipped animals (Davis and Ovaska 2001; McCarthy and Parris 2004). Other studies have noted inflammation and necrosis of clipped toes, suggesting this method may adversely affect mobility and survivorship (Davis and Ovaska 2001; Golay and Durrer 1994; Lemckert 1996). Recently, McCarthy and Parris (2004) questioned the ethics of toe-clipping based on findings that recapture rates in four studies decreased linearly with the number of toes removed.

One important assumption of mark-recapture studies is the mark has no influence on the survival or recapture probability of an animal (Donnelly and Guyer 1994). Thus, any direct or indirect impact of toe-clipping, such as negative effects on growth, health, or behavior may bias results unless those effects are known and can be accounted for during data analysis (Donnelly and Guyer 1994). Unfortunately, study results conflict over the existence and degree of such effects. Instances where toe-clipping did not affect survivorship or growth were documented by Ott and Scott (1999) for *Ambystoma opacum* and by Van Gelder and Strijbosch (1996) for *Bufo bufo*. However, the magnitude and cause of adverse impacts are difficult to quantify in the field and have not conclusively been addressed under controlled settings.

In a laboratory study, we evaluated the impact of toe-clipping on growth and survivorship of Squirrel Treefrogs (*Hyla squirella*). Conducting the study in a controlled setting allowed us to separate direct effects of toe removal on survivorship and growth due to physiological stress and wound infection, from possible indirect effects such as behavioral avoidance of capture locations and decreased foraging success or increased predation due to impaired mobility.

Methods.—Sixty-two adult *H. squirella* were collected in Baker County, Georgia, USA (31°13'16.88"N, 84°28'37.81"W) during November 2004 and maintained in the lab until sufficient numbers were gathered for the study. On 2 December 2004, frogs were weighed (± 0.01 g) and the snout-vent length (SVL; ± 0.1 cm) was

measured. To ensure that size at capture did not bias the results, frogs were sorted by body mass into small (N = 22, mean = 1.44 g, range = 1.10–1.86 g), medium (N = 20, mean = 2.22 g, range = 2.01–2.53 g) and large (N = 20, mean = 2.82 g, range = 2.59–3.21 g) size groups, and individuals within each size group were randomly assigned to one of two treatments (control or toe-clipped) using PROC SURVEYSELECT in SAS version 8.2 (SAS Institute Inc. 2001, Cary, North Carolina, USA). Each size group was equally represented in each treatment.

Animals in the toe-clipped treatment were marked by complete excision of the third toe on the left front foot and the fourth toe on the right rear foot with scissors sterilized in 95% ethanol. This mark corresponded to a mark of 72 under the Hero (1989) marking scheme. All wounds from toe removals were sprayed immediately with Bactine®, as recommended by Martin and Hong (1991). Animals in the control group were not toe-clipped or marked in any way. All animals were housed individually in 15 × 15 × 6 cm plastic Tupperware® containers on a substrate of moist paper towels. Frogs within the same size group were offered the same number and size of crickets 2–3 times a week. Crickets were dusted biweekly with Herpcare Cricket Dust®, which served as a vitamin supplement. All containers were maintained at a temperature of ca. 20ºC, and a 12:12 L: D photoperiod was maintained with full spectrum 60-watt incandescent bulbs hung 1 m above the containers. Individuals from each treatment were measured and weighed and their toes were examined monthly for signs of inflammation for five months. Survivorship of frogs from each group was also recorded. The sex of each frog was determined at the end of the study when secondary sexual characteristics (distended vocal sacs in males) were expressed with the onset of the breeding season.

Repeated measures analysis of variance was used to compare changes in SVL and mass among treatment groups using size group as a blocking variable. To test for any influence of sex on growth response variables, a separate repeated measures analysis of variance was used to compare SVL and mass among the sexes with size group as a blocking variable. Frogs with missing data (two escapes, and one death) were not included in the analysis. Analyses were conducted using the GLM procedure with a repeated statement in SAS version 8.2 (SAS Institute Inc. 2001, Cary, North Carolina, USA). This procedure produces both univariate and multivariate (Manova) tests for the effects of the treatments and time on the response variable.

Results.—One toe-clipped animal died of unknown causes during the fourth month, and two control animals escaped. Inflammation of clipped toes was recorded in nine animals (29%) during the first month and in two animals (6.5%) during the second month of the experiment. However, the wounds of all animals healed after 2 months, and no instances of tissue necrosis were observed.

Mean mass (t_{57} = -0.12, p = 0.91) and SVL (t_{57} = 0.28, p = 0.78) did not differ between treatment groups at the start of the experiment. Treatment had no effect on SVL ($F_{1, 55}$ = 0.00, p = 0.95) or mass ($F_{1, 55}$ = 0.10, p = 0.75), and there was no treatment by time interaction for either response variable (in both univariate and multivariate tests) (Figs. 1 and 2). However, both mass and SVL varied over time (mass: Wilk's lambda = 0.16, $F_{5, 51}$ = 52.63, p < 0.0001, univariate $F_{5, 275}$ = 40.91, G-G adjusted p < 0.0001; SVL: Wilk's lambda = 0.33, $F_{5, 51}$ = 20.60, p < 0.0001, univariate $F_{5, 275}$ = 29.07, G-G adjusted p < 0.0001). Neither SVL nor mass was significantly different between the sexes (SVL: $F_{1, 55}$ = 0.16, p = 0.69; Mass: $F_{1, 55}$ = 0.00, p = 0.98), and the sex by time interaction was not significant in any test.

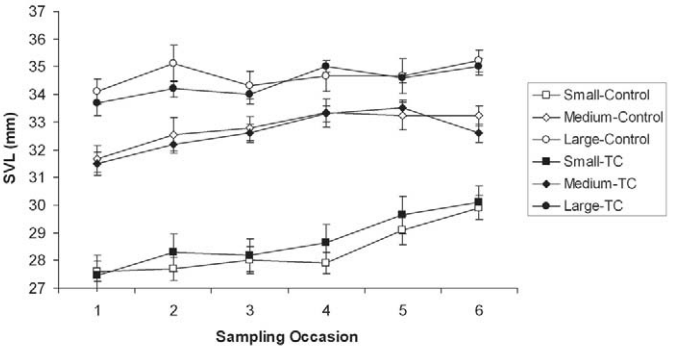

FIG. 1. Mean (± SE) SVL of toe-clipped (TC) and control frogs within different size groups sampled at 1 month intervals from December 2004 – May 2005. The 1 mm decrease between sampling events 5 and 6 for the medium sized toe-clipped group was due to measurement error.

Discussion.—Toe-clipping did not significantly affect the short-term growth or survivorship of *H. squirella* in this experiment. Our results are similar to those of Davis and Ovaska (2001) who examined the survivorship and growth of toe-clipped *Plethodon vehiculum* under laboratory conditions and to those of Ott and Scott (1999) who found no effects of toe-clipping on *Ambystoma opacum* maintained in small outdoor enclosures. Van Gelder and Strijbosch (1996) similarly found no differences in food consumption or mass between toe-clipped and unmarked *Bufo bufo* kept in small outdoor vivaria. Taken together these studies provide no evidence for a direct negative effect of toe-clipping on the health and growth of amphibians when they are provided ample food and maintained in a controlled, predator-free environment.

However, several studies conducted in field situations have demonstrated that amphibians marked by toe-clipping are recaptured less often than individuals marked by other methods, and that return rates are negatively related to the number of toes removed (Davis and Ovaska 2001; McCarthy and Parris 2004). In light of the laboratory studies, these observations suggest two possible

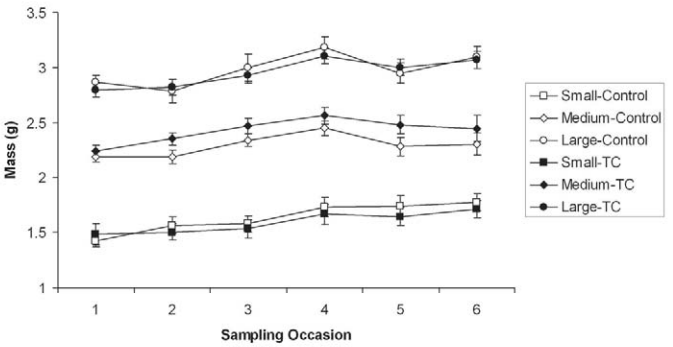

FIG. 2. Mean (± SE) mass of toe-clipped (TC) and control frogs within different size groups sampled at 1 month intervals from December 2004 – May 2005.

hypotheses: 1) toe-clipping may have an indirect negative effect on survival through increased predation and/or decreased foraging ability due to decreased mobility, 2) toe-clipping may affect amphibian behavior causing individuals to avoid capture locations. Evidence exists for both hypotheses. In a field experiment, Davis and Ovaska (2001) found that daily weight gain of *P. vehiculum* was significantly lower in toe-clipped animals than in unmarked individuals. However, they noted that both marked and unmarked *P. vehiculum* were consistently found under the same cover objects where they were initially captured. In contrast, Castellano and Giacoma (1993) found a negative correlation between the number of toes clipped and the number of days male *Bufo bufo* spent at a breeding pond. Similarly, Lemckert (1996) noted that 25% of newly toe-clipped *Crinia signifera* caught immigrating into a breeding pond left the pond within 1–3 days of marking, a behavior never observed in returning, previously marked individuals.

One consideration when gauging the impacts of toe-clipping is that individual species may be affected to different degrees and through varying combinations of mechanisms. Species with different feeding strategies, habits (e.g., arboreal vs. fossorial), antipredator behaviors, or habitat relationships may be differentially affected by the removal of one or more toes. Species also may vary in degree of susceptibility to stress or infection. For example, Lemckert (1996) found only rare incidences of infection in toe-clipped *C. signifera* but an almost 100 % infection rate in *Uperoleia laevigata*. Thus, marking by toe-clipping may be an effective, non-disruptive technique for some species but not for others.

The ethics of toe-clipping were recently questioned when McCarthy and Parris (2004) found that return rates of several frog species decreased linearly with the number of toes removed. Their study provides clear evidence that toe-clipping induces a negative effect on either the survivorship or the behavior of frogs. However, all available marking methods for amphibians involve the handling of animals and/or invasive procedures (see Donnelly et al. 1994), and it is likely that all marking methods induce some negative effect on the marked animals. In order to assess the ethics of toe-clipping and to determine the least disruptive marking method, the nature of the negative effects of toe removal should be fully understood. For instance, a marking method that results in a decrease in return rates due to behavioral avoidance of the capture site would be preferable to a method that results in a decrease due to mortality, particularly in the case of a rare or protected species. Unfortunately, few studies have compared the effects of toe-clipping to other marking methods (see Davis and Ovaska 2001) and the effects of other marking procedures on amphibian health and behavior are poorly known.

It should be emphasized that this study had several limitations, which should be carefully considered when interpreting the relevance of our results to the practice of toe-clipping in field studies. First and foremost, this was a laboratory study in which frogs were maintained in small enclosures in a predator-free, constant environment with an abundant and easily accessible food supply. This study could therefore not measure negative effects on the climbing ability and general mobility of the treefrog *Hyla squirella* or assess any influence of toe removal on behavior. However, given the importance of the adhesive toe discs of treefrogs in climbing and movement, it is likely that toe-clipping does have a negative effect on the mobility of this species. In addition, it is possible that our study animals healed at a different rate than they would have in the wild where a wider range of thermal environments, food items, and opportunities for infection exist. Secondly, all excision wounds in this experiment were treated with antiseptic, which may not be a common practice in most field studies. Our results may therefore represent an underestimate of the negative impacts of toe-clipping on growth and survivorship compared to field studies where antiseptic is not used. However, despite the limitations of this study, we believe our results add to a growing body of evidence that suggests that the negative impacts of toe-clipping observed in field studies are related to factors other than direct health effects.

Acknowledgments.—We thank R. Cooper, L. M. Conner, and K. Parris for providing helpful comments on this manuscript, and S. Becker for assistance with animal care. Animals were collected under Georgia Department of Natural Resources scientific collecting permit number 29-WMB-04-188, and toe-clipping and husbandry procedures were conducted under University of Georgia Institutional Animal Care and Use Committee guidelines (permit number A2004-10190-C1).

Boreal Toads (*Bufo boreas boreas*) are found throughout much of the western United States, and were historically viewed as common. Presently, this taxon is considered a species of concern in some western states (Maxell et al. 2003; McGee et al. 2002) and populations in the southern Rocky Mountains have decreased to the extent that they have been considered for listing under the Endangered Species Act (U.S. Fish and Wildlife Service 2005). Although a causal link has not been established, rapid declines in Boreal Toad populations have been associated with the presence of the chytrid fungus *Batrachochytrium dendrobatidis* (hereafter *Bd*) in northern Colorado (Muths et al. 2003; Scherer et al. 2005) and *Bd* has been implicated in the mass mortality of several other species of amphibians (Quellett et al. 2005; Rachowicz et al. 2006).

Accurately monitoring trends in Boreal Toad abundance and distribution is difficult partly because population surveys often rely on qualitative observations at or near breeding areas (Loeffler 2001). Temporal variation in habitat availability (Bartelt et al. 2004), explosive breeding behavior (Olson et al. 1986), periodic recruitment failures (Olson 1992), high turnover in the use of breeding areas (Trenham et al. 2003), and difficulty in detecting breeding assemblages (Hammerson 1999) may lead to substantial fluctuations in actual and perceived toad abundance (Corn et al. 2005; Heyer et al. 1994; Wente et al. 2005). Consequently, alternative methods for detecting the presence and relative abundance of Boreal Toads would be useful. Recently, researchers in Montana studying the summer movements of stream fishes coincidentally captured large numbers of downstream-drifting Boreal Toads in hoop nets (Adams et al. 2005). Subsequent netting directed at assessing in-stream movements by Boreal Toads detected them in many previously unsampled basins (M. Young and D. Schmetterling, unpubl. data). If use of streams by Boreal Toads is geographically widespread and temporally consistent, the installation of upstream-facing hoop nets may increase the options for sampling toad populations (cf. Heyer et al. 1994; Willson and Dorcas 2004).

Substantial testing for *Bd* in amphibians has been done at historical and current Boreal Toad breeding locations in Colorado, Utah, and Montana (Muths et al. 2003; Boreal Toad Conservation Team, unpubl. data), but only limited sampling has been done in Wyoming. Testing for *Bd* in amphibians in Wyoming began in earnest around 2000 in the Laramie River basin, with additional testing in portions of the Green River drainage in 2002 and more recent sampling in other portions of the state (W. Turner, Wyoming Game and Fish Department, pers. comm.). Determining the distribution of *Bd* is critical to identifying Boreal Toad populations at risk of declines from infection and to locating populations free from disease that might be used for reintroductions elsewhere, as well as describing its prevalence in amphibians in areas where boreal toads are no longer extant but other amphibians may be at risk.

Our study had three objectives: 1) determine whether hoop-net sampling could detect the presence of Boreal Toads in streams on the Medicine Bow-Routt National Forests of south-central Wyoming and north-central Colorado; 2) compare the relative efficiencies of visual encounter surveys and in-stream, hoop-net sampling for detecting Boreal Toads; and 3) assess the prevalence of *Bd* among amphibians detected by this sampling, by targeted breeding site surveys not evaluated as part of this study, or found incidentally in this region in 2004 and 2005.

Methods.—Hoop nets were placed in first- to third-order streams across the Medicine Bow-Routt National Forests during July and August 2004 and 2005 (Fig. 1). In 2004 and 2005, we hoop-net sampled streams adjacent to, or connected by the stream network to locations known to recently have Boreal Toads (based on breeding season or summer visual encounter surveys not associated with this study, N = 19). Of the 13 locations in which Boreal Toads had been observed or known to breed since 1996, the 11 with the most readily accessible streams were subsequently sampled with hoop nets at sites 0.1–8.0 km from the breeding or observation locations. Also in both years, we sampled randomly selected streams (N = 46) if their basins supported potential amphibian breeding habitats (lakes, ponds, or wetlands, usually in the vicinity of the stream and upstream from net locations). Individual streams were hoop-net sampled in only one year. The average elevation at net sites was 2657 m (range 2260–3014 m) and channel low-flow wetted widths averaged 3.3 m (range 0.3–11.6 m). Dominant stream substrate varied from small gravel to rubble and boulder. Willows (*Salix* spp.), Aspen (*Populus tremuloides*), and occasionally conifers dominated most riparian areas.

We installed hoop nets in 1–6 sites at least 1 km apart within each stream, depending on stream length and access. Each hoop net was 1.4 m long, had four 38-cm hoops, two leads 1–4 m long, and a single throat with a 5.0–7.5 cm opening, and was constructed of Delta heavy 44, 6.3-mm nylon mesh (Miller Net Company, Memphis, Tennessee). Costs per net averaged US $165. Nets were set in the channel thalweg and affixed to rebar driven into the stream bottom or banks. The opening of each net faced upstream and the leads were angled slightly upstream to direct downstream-drifting toads into the net. On average nets intercepted 1.2 m (range 0.4–1.8 m) of the wetted width of the channel. Nets were partially submerged such that the throat was underwater and the upper portion of the leads, first hoop, and cod end were above the stream surface to intercept toads drifting near the surface and to provide a resting area for captured toads.

Nets were installed as flows declined in summer and were monitored daily over the 9-d interval they occupied each site. This interval was chosen because probability of capture of at least one

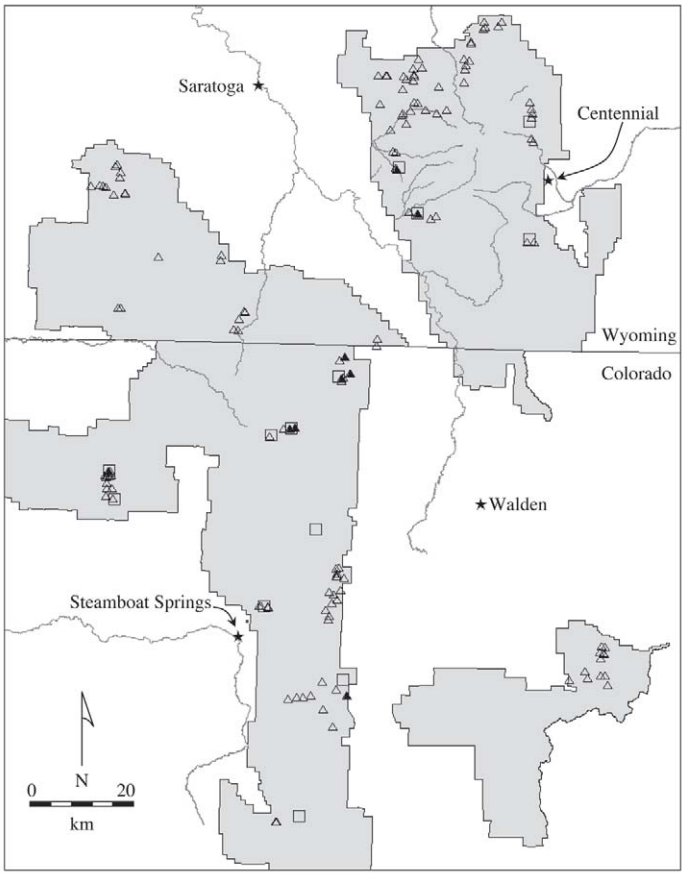

FIG. 1. Locations of sites monitored with hoop nets in 2004 and 2005 and locations of recent breeding areas on the Medicine Bow-Routt National Forests (shaded area). Filled triangles = sites where Boreal Toads were captured in hoop nets in 2004 and 2005 (N = 9); open triangles = sites without captures in hoop nets in 2004 and 2005 (N = 136); and open squares = breeding locations or sites with observations since 1996 (N = 13).

boreal toad exceeded 76% with this sampling intensity during midsummer in Montana streams (M. Young and D. Schmetterling, unpubl. data). Occasionally this period was shortened if nets incurred damage or Beaver (*Castor canadensis*) activity inundated or clogged them.

Upon capture, all toads were weighed (±1 g) and measured (snout–vent length, ±1 mm). Toads were sexed by inspecting the inner toes on the front legs for roughened nuptial patches and by attempting to induce them to vocalize by applying gentle pressure behind the front legs. Boreal Toads < 55 mm were considered to be juveniles (Hammerson 1999; Nussbaum et al. 1983) unless they vocalized or possessed nuptial pads. All toads > 55 mm were marked with a passive integrated transponder (PIT) tag inserted underneath the skin along the dorsal midline and posterior to the parotoid gland (Camper and Dixon 1988). An outside rear toe was clipped at the first joint and sealed with surgical cement to provide a secondary mark. All toads of this size were also checked for marks to identify previously captured individuals. After handling, toads were released downstream from the capture site.

We also conducted visual encounter surveys (Heyer et al. 1994) by making a sinuous traverse of the riparian areas along each side of the channel (including inspection of the stream) near net sites. These traverses extended 1 km upstream or until valley walls constrained the channel and effectively eliminated low-gradient, near-channel habitats. Most riparian surveys were completed up to a month prior to net installation when the probability of detecting breeding adults or egg masses was higher. Each Boreal Toad observed during these surveys was measured and marked, as previously described, and its location noted. Finally, the time necessary to complete hoop-net sampling and visual encounter surveys was recorded for work conducted in Wyoming.

Most live and dead amphibians captured in hoop nets and visual encounter surveys, as well as those found during monitoring of known amphibian breeding areas or located opportunistically, were tested for *Bd*. In general, handling procedures followed Livo (2004). For live animals, we sampled for *Bd* by obtaining skin swabs and conducting genetic analyses because this method is less injurious and yields rates of detection comparable to those of more intrusive sampling when tested on known *Bd*-positive individuals (Livo 2004). We used scissors to remove toes or ventral skin patches from dead animals (N = 3). Samples were submitted to a laboratory (Pisces Molecular, Boulder, Colorado) for detection of fungal DNA using a PCR assay.

Results.—In 2004 and 2005, we sampled for 1267 trap-days at

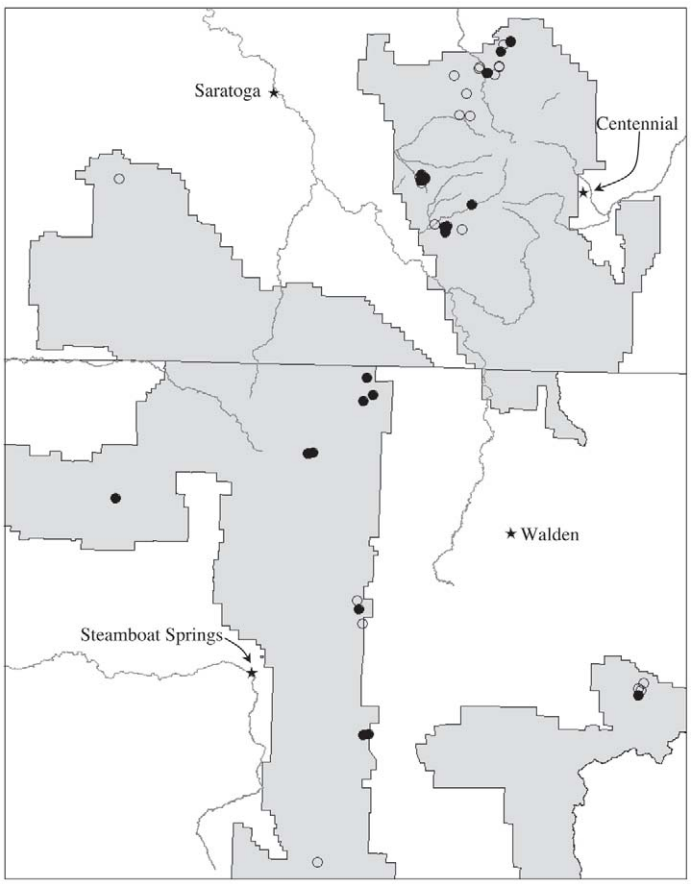

FIG. 2. Locations of amphibian samples from five species that were tested for *Batrachochytrium dendrobatidis* (*Bd*) in 2004 and 2005 on the Medicine Bow-Routt National Forests (shaded area). Filled circles = *Bd* detected (N = 20 sites, 81 individuals) and open circles = *Bd* not detected (N = 19 sites, 105 individuals). Note that not all amphibians captured were tested.

145 net sites on 65 streams on the Medicine Bow-Routt National Forests (Fig. 1). At or near nine net sites on eight streams—Beaver Creek, S. Fk. Big Creek, N. Fk. Elk River, Grizzly Creek, Torso Creek, and Twisty Creek in Colorado and Barrett Creek and Sourdough Creek in Wyoming—we captured 40 toads (6 males, 8 females, and 26 juveniles), of which 37 were first caught in hoop nets and 3 during visual encounter surveys. We caught 1–6 toads over the 9-d netting interval in seven of these streams, and 20 juvenile toads in Torso Creek. Marked toads were recaptured on five occasions; all recaptures were within 3 d of the initial marking. Four of these were made adjacent to the stream in the vicinity of the hoop nets where the toads were initially captured, and one marked toad was recaptured in the same net where it was first caught. All toads found in hoop nets were alive with one exception (this toad tested positive for *Bd*), and it is unknown whether this animal was already dead at the time of capture. All toads observed during visual surveys were alive.

Although hoop nets produced more captures than did visual encounter surveys (and visual encounter surveys only detected toads in those locations adjacent to net sites producing captures), other measures of sampling efficiency suggested some shortcomings of using hoop nets. Hoop-net sampling resulted in captures of boreal toads near only 6 of 11 locations with relatively recent (since 1996) observations of Boreal Toads or toad breeding areas, although Boreal Toads may have been absent from some of these locations by the time hoop-net sampling was conducted; toads were captured near all locations with observations since 2000. Mean distance from known breeding areas to net sites with captures was 1.1 km (range 0.1–4.2 km). Also, Western Chorus Frogs (*Pseudacris triseriata*) were the only other amphibians captured in hoop nets (N = 5), whereas Northern Leopard Frogs (*Rana pipiens*) and Wood Frogs (*Rana sylvatica*) also were observed (but not counted) during visual encounter surveys. On average, it required 4.5 h for a crew of two people to monitor 10–15 nets, depending on road conditions and the distance between sites. Days on which traps were installed required an additional 6 h. Visual encounter surveys required approximately 1 h for two people to examine 1.6 ha.

Amphibians infected with *Bd* were present in many portions of the study area. Of the 186 amphibians sampled at 39 locations in 2004 and 2005, 81 individuals from 20 locations were positive for *Bd* (Fig. 2). Overall, 54 of 102 Boreal Toads tested positive for the presence of *Bd* and 14 of 16 locations with Boreal Toads that were tested (including eight sites where toads were detected with hoop nets or visual encounter surveys) were positive. Also, 21 of 54 Western Chorus Frogs, 3 of 5 Northern Leopard Frogs, and 3 of 24 Wood Frogs were positive for *Bd*; the lone Tiger Salamander (*Ambystoma tigrinum*) tested negative.

Discussion.—Although earlier studies gave anecdotal (Carpenter 1954) or indirect (Campbell 1970) evidence of stream use by Boreal Toads in Colorado and Wyoming, our study confirms their presence in streams in this region (cf. Muths et al. 2001), and suggests that stream-related movements by Boreal Toads might not be restricted to populations in the northern Rocky Mountains. However, not all locations that support populations of Boreal Toads have perennial streams (e.g., northeastern Utah; Thompson et al. 2004), thus their use of such habitats might be regarded as somewhat opportunistic.

The 37 Boreal Toads captured in nine hoop nets were far fewer than those detected in western Montana watersheds using a similar sampling regimen. For example, in brief late summer sampling in 2001 and 2002 in three western Montana streams, Adams et al. (2005) made over 250 captures of Boreal Toads in hoop nets, and additional in-stream trapping in this area during portions of two subsequent summers produced 497 captures of Boreal Toads from 16 of 21 streams sampled (M. Young and D. Schmetterling, unpubl. data). These regional differences in captures are consistent with the perception of widespread and rapid declines of this species in the southern portion of its range (Carey et al. 2005; Corn et al. 2005). Nevertheless, the actual distribution of Boreal Toads is probably greater than that determined from in-stream trapping, but how much greater is uncertain because the probability of detection using this method is unknown and the design we employed did not permit an evaluation of detection probabilities (sensu MacKenzie et al. 2002).

All captures of Boreal Toads in nets were associated with areas with recent (since 2000) observations (cf. Wente et al. 2005), but only 9 of 20 nets in these streams captured toads. As part of our field protocol, we concentrated sampling downstream from known or potential breeding areas based on the assumption that Boreal Toads would disperse in this direction following breeding. However, in the two instances in which we set a net upstream from an existing breeding area, both captured Boreal Toads. It might be more likely that individuals disperse after breeding via terrestrial movements (Bartelt et al. 2004), perhaps farther up in a basin, or that non-breeding individuals might have used the stream channel above breeding areas. Comprehensive investigations of the pre- and post-breeding movements of sexually mature Boreal Toads and of non-breeding individuals are necessary to resolve this uncertainty.

In-stream sampling in summer was more effective for detecting the presence of Boreal Toads than roughly concurrent visual encounter surveys in the same basin. This might be because Boreal Toads are cryptic and are difficult to locate outside the breeding season (Hammerson 1999; Keinath and McGee 2005) when they are largely nocturnal (Gregory 2000; Hailman 1984; M. Young and D. Schmetterling, unpubl. data). However, visual encounter surveys appeared to require less time to complete, and were more effective for detecting the entire suite of amphibians present in this region. Although hoop nets can be checked in 5 min and installed in 15 min by experienced individuals (M. Young, pers. obs.), much of the effort associated with hoop-net surveys is related to the spatial distribution of hoop nets, which in this study required traveling on average 75 km on unimproved forest roads each day. Moreover, we caution that because hoop-net sampling did not consistently detect Boreal Toads near all locations where they were known to be breeding in recent years, it cannot be considered a replacement for targeted surveys of breeding areas.

In-stream trapping revealed some aspects of these populations that might have been overlooked by other techniques. For example, we inferred that Boreal Toad recruitment was successful in 2004 in the Torso Creek watershed, based on captures of juveniles that metamorphosed the previous summer. Their presence may be a more reliable indicator of reproductive success than observations of egg masses, tadpoles, or recently metamorphosed toads, given the potentially high rates of mortality of each of these life stages

(Biek et al. 2002; Carey et al. 2005). Furthermore, sex ratios were much closer to unity than typically observed at breeding areas (Olson et al. 1986; Thompson 2004).

Based on our sampling, *Bd* appears to be widely distributed throughout south-central Wyoming and north-central Colorado (51% of sites tested), and was present in the majority (53%) of Boreal Toads that were tested. Positive samples were collected from the Elkhead Mountains, Park Range, Never Summer Mountains, and Sierra Madre in Colorado and from the Medicine Bow Mountains in Wyoming. We did not detect *Bd* in samples from the Wyoming portion of the Sierra Madre, but owing to the rarity of samples of amphibians from there, this is not conclusive evidence that *Bd* is absent. Because these locations were not previously sampled for *Bd*, it is not possible to determine if its prevalence is a recent phenomenon. Nevertheless, the putative arrival of *Bd* in central Colorado coincided with a rapid decline in Boreal Toads (Corn et al. 2005), and similar circumstances might explain the apparent current rarity of Boreal Toads in the study area. Also, the presence of *Bd* at many locations and among most Boreal Toad populations suggests that, should reintroductions of Boreal Toads be attempted, ensuring that breeding areas remain disease-free might prove problematic.

In summary, we established that Boreal Toads of the southern Rocky Mountain populations may use streams in mid-summer and can be captured by using upstream-facing hoop nets. This approach was more successful at detecting Boreal Toads than were visual encounter surveys in the same area. However, the failure to capture Boreal Toads in all nets near locations suspected to support breeding populations indicates that stream-based netting alone is inadequate for assessing their status, and might better serve as a complement to targeted breeding area surveys or for the detection of toads in previously unrecognized locations. Finally, the limited number of captures of Boreal Toads, and of captures only in association with locations where this species had recently been observed, is consistent with the perceived large-scale reductions in distribution and abundance of Boreal Toads in this region and that this apparent decline might be associated with the high prevalence of *Bd* among Boreal Toads and other amphibians in this area.

Acknowledgments.—We thank C. Daily, G. Eaglin, L. Ellsworth, J. Fitzpatrick, Z. Hayden, J. McCumber, S. Kozlowski, M. Miller, J. Nachtmann, C. Plotner, R. Vacirca, M. Waugh, and K. Willford (Medicine Bow-Routt National Forests), L. Bender and D. Paddock (Saratoga National Fish Hatchery), W. Turner (Wyoming Game and Fish Department), P. Many amphibian populations are thought to be structured as metapopulations across a landscape (but see Smith and Green 2005), particularly those species breeding in isolated temporary ponds (e.g., Gill 1978, Hecnar and M'Closkey 1996, Skelly 2001). In terms of Levins' (1969) classic metapopulation concept, isolated wetlands could serve as demes or subpopulations in a larger metapopulation context. This also includes the uplands surrounding isolated wetlands for those species that migrate between upland refuges and isolated breeding sites. Because of variable hydroperiods or presence of predators (e.g., some fishes), certain ponds may be subject to prolonged periods without sufficient hydroperiod to allow metamorphosis (e.g., Semlitsch et al. 1996), whereas others may persist through time and allow the production of metamorphs to maintain populations (sources). A prolonged period of metamorphic failure could lead to a local extinction event. Should conditions change, sites from which populations had been extirpated might be recolonized via dispersal of individuals from source populations. This dynamic interplay of occupancy, colonization and local extirpation thus produces a mosaic of occupation scenarios at any point in time. As Marsh and Trenham (2001) point out, however, this model is somewhat simplistic since there are many variables which affect landscape occupancy by pond-breeding amphibians, including various deterministic factors, the distribution of terrestrial habitats, and the isolation of the pond "patches."

Despite the general acceptance of the metapopulation model, few studies have demonstrated amphibian colonization of a former breeding site after a long absence (see Taylor et al. 2006 for a possible example involving *Eurycea quadridigitata* after 8 years) or colonization of previously unsuitable sites. Here, we report on the colonization of aquatic breeding sites by the Striped Newt (*Notophthalmus perstriatus*) in north-central Florida after a period of 10 years or more with no water, or under previously unsuitable conditions, and suggest that Striped Newts may form metapopulations. Metapopulation dynamics have important implications for the conservation and management of this imperiled species (Dodd et al. 2005). For example, for Striped Newts to persist as metapopulations it is crucial to protect a suite of wetlands with a diversity of hydroperiods and to properly manage uplands to facilitate dispersal among ponds.

For five years, Breezeway Pond on the Ordway-Swisher Biological Station, Putnam County, Florida was monitored five days per week using an encircling drift fence-pitfall trap sampling procedure (see Dodd 1992 for details of this study). Hydroperiod was monitored daily. From 1985 to 1990, > 2500 Striped Newts were marked as they entered and exited the 0.16 ha pond. During the latter half of the study (1988 - 1990), a prolonged drought affected north-central Florida (Franz 1991) and Breezeway Pond went dry on 23 December 1988. Captures of Striped Newts declined accordingly, from 744 in 1987 to 16 in 1990 (Dodd 1993). After October 1990, Breezeway Pond was periodically checked for the next 10 years, especially after substantial rain events, to monitor its hydroperiod. It did not refill until January 1998. During this period the pitfall traps were closed and the drift fence was opened in numerous places to allow animals to move freely in the dry pond basin. On 8 May 1998, a larval Striped Newt was collected from the pond (UF 133756). Despite rigorous dip-net sampling of the pond, which was less than 0.1 hectares in extent at the time, only four larval newts were captured. Although we cannot be sure, this could indicate that very few adults, which migrate to Breezeway Pond in the winter (Dodd 1993), recolonized the pond.

Smith Lake is a 7.55 ha clear-water lake located 350 m N of

Breezeway Pond. It had been stocked with fish when the station was a private hunt club (prior to 1980). In 1983, fish surveys documented the presence of *Etheostoma fusiforme, Gambusia holbrooki, Lepomis macrochirus,* and *Micropterus salmoides* (R. Franz, pers. comm.). During aquatic surveys prior to 1990, no Striped Newts were collected in the lake, which was not surprising since Striped Newts do not inhabit ponds with predatory fishes (Dodd et al. 2005). However, a small isolated wetland (Smith Lake Pond #1, ca. 425 m east of Smith Lake) had Striped Newts on 9 April 1993 (UF 91485). Smith Lake dried on 29 May 1990 because of a severe drought that affected many lakes and wetlands on and near the Ordway-Swisher Biological Station (Franz 1991) and remained dry for several years before refilling. No fishes have been found in the lake since it dried completely in the early 1990s. Striped Newts were collected from Smith Lake for the first time on 1 February 1997 (UF 133789), again on 2 November 1997 (UF 125759), and most recently on 20 April 2005 (no voucher collected).

A similar situation occurred at a neighboring wetland, Blue Pond (0.71 ha basin), on the Ordway-Swisher Biological Station. Prior to the mid-1980s, when the Station was in private ownership, Blue Pond was a popular fishing site. In the spring of 1985, approximately 100 largemouth bass were caught in Blue Pond (S. Scaife pers. commun.). Blue Pond dried completely in 1989 during the same severe drought that caused Smith Lake and Breezeway Pond to dry. No fish have been found in Blue Pond since the drought. Striped newts were first documented in Blue Pond on 9 February 1997 (UF 128031), and most recently on 11 November 2006 (no voucher taken). They have been documented in Blue Pond numerous times during the interim between these dates. Because Striped Newts only breed in fishless ponds, and thus to our knowledge did not occur in Blue Pond prior to the drought, this is another example of colonization of previously unsuitable habitat by the species.

Salamanders are known to colonize breeding sites after the extinction of predatory fish. Funk and Dunlap (1999) conducted surveys for introduced trout and native Long-toed Salamander larvae in high elevation lakes in 1978 and again in 1997/1998. They found evidence to suggest that Long-toed Salamanders were able to colonize lakes in which trout went extinct. This is similar to our findings with Striped Newts at the Ordway-Swisher Biological Station. Population estimates at known Striped Newt breeding ponds on the biological station vary. Dodd (1993) documented 2521 individuals over a 62.5 month period (1985–1990) at Breezeway Pond. During a two-year period (1996–1998), Johnson (2002) counted 8127 Striped Newts entering and exiting One Shot Pond. However, Johnson (unpubl. data) only found 32 individuals at neighboring Fox Pond during a 270-day period from Nov 1997 to Aug 1998. Drift fences encircled both of these ponds. Despite herpetologists working on the biological station for the past 25 years and sampling many of the station's wetlands, this was the first time Striped Newts were documented in Fox Pond and thus may represent a colonization or recolonization event. Fox Pond is very isolated from other wetlands and likely never supported predatory fishes naturally.

Striped Newts have been found in 12 ponds on the Ordway-Swisher Biological Station, all of which have dried for varying lengths of time during the last three decades. The larger wetlands (Smith Lake, Blue Pond, Clear Pond) and two deep but small ponds (Berry, One-Shot) have the longest hydroperiods, but even at these locations drought may completely eliminate or severely limit the duration and timing of suitable conditions for Striped Newt breeding. At such times, Striped Newts may attempt to disperse to other wetlands if available. Striped Newts have been found terrestrially 700 m from the nearest possible breeding site (Dodd 1996), and an inter-pond movement of ca. 685 m (movement of a marked newt from One Shot Pond to Fox Pond) was recorded on the Ordway-Swisher Biological Station (Johnson 2003). Johnson (2003) suggested that 16% of a Striped Newt breeding population may migrate > 500 m from non-breeding terrestrial habitats to reach an isolated breeding pond. Although they have the ability to migrate hundreds of meters into upland habitats, there appears to be strong philopatry to natal breeding ponds, and inter-pond dispersal is a relatively rare event. This supports our supposition that Striped Newts form metapopulations because it means that recruitment is more likely to come from within a patch (e.g., breeding pond and surrounding uplands) rather than via immigration from nearby patches (Harrison and Taylor 1997).

Understanding the synchrony of local population dynamics is important for differentiating between patchy populations and true metapopulations (Harrison and Taylor 1997; Hecnar and M'Closkey 1996). Unfortunately, details of the synchrony of pond occupancy (e.g., extinction and recolonization rates) by Striped Newts across all potential breeding ponds on the Ordway-Swisher Biological Station are unknown. Long-term studies among multiple patches (ponds) are required to collect such data. Nonetheless, we believe our data support the hypothesis that Striped Newts on the station persist as a metapopulation. Because of environmental stochasticity (e.g., drought, predator colonization), local extinctions are likely over time for Striped Newt breeding ponds on the station. Variation in pond hydroperiods leads to variation in the synchrony of extinction events.

The source of the individuals that recolonized Breezeway Pond after 10 years, as well as the source of animals that colonized Smith Lake and Blue Pond following the drought, remains unknown. They likely originated from another breeding pond as part of a metapopulation at the Ordway-Swisher Biological Station, as suggested above. Alternatively, it is possible that in some situations individual Striped Newts may wait out short-term droughts in terrestrial refugia. Eastern Red-spotted Newts (*N. viridescens*) may live > 8 years (Forester and Lykens 1991; Gill 1985), although attempts to age Striped Newts have been unsuccessful (G. Zug, pers. comm.). A single individual *N. perstriatus* from the Ordway-Swisher Biological Station has been kept in captivity since 1991, a period of 15 years (L. LaClaire, pers. comm.). Thus, it is possible that wild Striped Newts are long lived.

Like *N. viridescens* (Gill 1978), *N. perstriatus* seems to fulfill the criteria (patchy occupancy through time of a series of breeding ponds in close proximity; periodic extinction and recolonization due to stochastic environmental fluctuation; potential for long distance dispersal; inter-pond movement) for having a metapopulation structure. Surveys for this declining species need to take into consideration the extent to which individuals and populations are dispersed across a landscape over time. What appears to be an unoccupied or unsuitable site during a short-term survey may be an important location for metapopulation dynamics during optimal

environmental conditions.

Acknowledgments.—We thank John Eisenberg and Dick Franz for granting permission to work on the Ordway-Swisher Biological Station, Dick Franz and Sonny Scaife for information on fishes in Smith Lake and Blue Pond, Linda LaClaire for sharing data on her captive Striped Newt, and numerous field assistants who have aided us in sampling Striped Newt populations for the last 20 years.

The Diets of Three Sympatric Barred River Frogs (Anura: Myobatrachidae) from Southeastern Australia

FRANCIS LEMCKERT

School of Biological Sciences, The University of Sydney

There are five species of large (7–10 cm) ground-dwelling myobatrachid frogs of the genus *Mixophyes* found along the coast and adjacent ranges of eastern Australia (Cogger 2000). This genus is of some conservation interest because three species (*M. balbus, M. iteratus,* and *M. fleayi*) have had major declines in numbers and ranges in recent years, presumably due to the chytrid fungus, *Batrachochytrium dendrobatoides*, and habitat loss (Ehmann 1997; Hines et al 1999). Advancing knowledge of their basic biology is imperative for their long-term conservation.

The diet of the *Mixophyes* has been poorly documented. Cogger (2000) notes that they generally feed on "insects and smaller frogs." However, the only specific published report of any kind is Wotherspoon's (1980) note of Leaf Green Tree Frogs (*Litoria phyllochroa*) in the stomach of a *M. fasciolatus*. We document the gut contents of three of the species of barred river frogs (*M. balbus, M. fasciolatus,* and *M. iteratus*) to determine if there is any obvious dietary specialization that might be of importance in the declines of *M. balbus* and *M. iteratus*.

Preserved specimens from each of the three species were obtained from the collections of the Australian Museum, Melbourne Museum, and the Australian Wildlife Collection. These specimens come from a wide range of sites and span more than 100 years in time. Each specimen was sexed and the contents of the gut cavity removed and placed into a separate specimen tube along with the corresponding museum identification number. Each was examined later in order to identify the number of food items present and, as far as possible, the identity of the prey items. Where an item could be clearly distinguished, it was identified to the family level for insects and order for the other items. Initially, we attempted to estimate the volumes of each food item, but the inconsistent nature of digestion made useful comparisons impossible and this approach was abandoned. Individuals were assigned a sex based on obvious secondary or internal sexual characteristics and were considered sub-adults if less than 5 cm snout–urostyle length (SUL) and showed no distinct sex.

We described diet composition, but did not attempt statistical data analysis because of the small number of individuals containing food items. Furthermore, exploratory analysis (using Principle Component Analysis and Analysis of Variance) revealed that the gut contents of a few individuals with much larger numbers of prey strongly influenced any statistical testing, confounding the

analysis interpretation.

Each species ate a broad range of food items that included various invertebrate groups such as spiders, centipedes, and snails (Tables 1–3). Insects dominated the diets: *Mixophyes balbus*, 25/30 = 83%; *M. fasciolatus*, 34/44 = 77%; and *M. iteratus*, 19/36 = 53%. *Mixophyes iteratus* ate a greater range of non-insect items with eight non-insect groups being recorded, whereas both *M. balbus* and *M. fasciolatus* each included only three non-insect groups. Spiders were the most prevalent non-insect eaten (12/32 non-insect items = 37%). Overall, 105 of the 110 (98%) dietary items were invertebrates. Of the remaining dietary items, the *M. iteratus* sample included two frogs. One could not be identified, but the other was a stream-breeding species, the Tusked Frog, *Adelotus brevis*. Additionally, small skinks were found in the diet of both *M. iteratus* and *M. balbus*.

The dietary samples for the three *Mixophyes* species suggest that there was no particular dietary specialization. This is in keeping with the limited available information on Australian frogs which indicates that most species are dietary generalists and that larger species have varied and broad diets (Barker et al. 1995; Tyler 1994). All three species of *Mixophyes* are reasonably large frogs (*M. iteratus* females reach up to 12 cm SUL; *M. balbus* and *M. fasciolatus* reach 7–10 cm SUL; Cogger 2000) that likely attempt to eat any potential prey items they encounter when foraging. If anything, smaller prey items such as collembolans, amphipods, ants, or termites appeared to be relatively rare within the guts of the sampled specimens. These have been found to be important prey items for smaller (and often sympatric) species of Australian myobatrachid frogs (Cappo 1986; MacNally 1983), but relatively small invertebrates may not be worth the effort of capture by the large adult barred river frogs. Sub-adults of all three *Mixophyes* species may eat these smaller prey items, however we sampled few frogs of less than 5 cm SUL.

Mixophyes iteratus appeared to have a wider prey base and ate relatively fewer insects than the other two species in our sample. Insects form the major part of the diets of nearly all Australian frog species on which we have information (Tyler 1994). The fact that this is such a large-bodied species may allow it to take larger non-insect prey such as centipedes and frogs as well as large "king" crickets (up to 7 cm long; F. Lemckert, pers. obs.), and typically it is the larger frogs in Australia that are recorded eating large prey items (e.g., *Litoria raniformis*: Fleay 1935; *Litoria caerulea*: Tyler 1994).

Dietary difference may originate from frog habitat preferences. While *M. iteratus* breeds in streams (Barker et al. 1995; Cogger 2000), it appears to be relatively restricted to riparian areas in wetter forest types (Lemckert and Brassil 2000). The stream-breeding *M. balbus* and, particularly, the pond-breeding *M. fasciolatus* for-

age in drier forest away from the riparian zone (Lemckert and Morse 1999). Nematodes, amphipods, and gastropods would generally prefer moister environments and are likely to be more prevalent in riparian areas so *M. balbus* and *M. fasciolatus* may not encounter the riparian-associated wider prey base of *M. iteratus*. The partial dominance of crickets in the diet of *M. fasciolatus* might be explained by its greater occurrence in drier forest areas. However, there is not enough evidence on the distribution of crickets in these forest environments to know if this is the case or whether they preferentially target crickets in the diet.

The dietary intake from this study suggests it is unlikely that a decline in specific prey items has played a significant role in the declines of *M. iteratus* and *M. balbus*. They do not have obvious specializations on particular prey groups that could lead to impacts on populations if specific prey bases declined. The diets of the sub-adults may be more specialized and so affected by disturbances and should be explored further, although the limited data we obtained suggested that the diets of these smaller individuals were as broad as the adults.

Acknowledgments.—Thanks to Ross Sadlier and the Australian Museum, Jane Melville and the Melbourne Museum, and Robert Palmer and the Australian Wildlife Collection for making specimens available. We also thank Rod Kavanagh and Traecey Brassil for their comments on the manuscript, and Forests NSW for support.

Artwork and Images Wanted for *HR*

We are always interested in obtaining illustrations of herpetological subjects for publication in *Herpetological Review*. Generally, original drawings should be of a scale that would permit reduction to fit a 90-mm wide column. Original art, or high quality photocopies, should be packaged to ensure safe delivery and sent to the Editor. Alternatively, we would be pleased to receive material in electronic format; consult the Editor for appropriate file formats and sizes.

Also, we are interested in evaluating outstanding color slides or high-resolution digital images of amphibians and reptiles for possible use on future *HR* covers. When reviewing material for submission, photographers should keep in mind the vertical format of our covers. In addition to highlighting outstanding photography, our cover subjects should lend themselves to communication of biologically interesting information through accompanying text. If you would like to have your work considered, please contact the Editor ***prior*** to sending any material. We prefer to review images as JPEG or PDF files before requesting examination of original slides. Postal and e-mail addresses are listed on the inside front cover.

Natural History Notes on *Crotalus tancitarensis* (Serpentes: Viperidae)

JAVIER ALVARADO-DÍAZ*
ALFREDO ESTRADA-VIRGEN
and
IRERI SUAZO-ORTUÑO
INIRENA, Av. San Juanito Itzicuaro s/n, Col. Nueva Esperanza CP 58330 Morelia, Michoacán, México

**Corresponding author; e-mail: herpfin1947@yahoo.com*

The Tancítaro Cross-banded Mountain Rattlesnake, *Crotalus tancitarensis*, is only known to inhabit the upper elevations of the volcano known as Cerro Tancítaro in Michoacán, México. The species was recently described from three specimens by Alvarado-Díaz and Campbell (2004), who placed it in the *Crotalus intermedius* species group of Mexican montane rattlesnakes, which also includes *C. intermedius*, *C. pricei*, and *C. transversus* (Murphy et al. 2002). This report provides information on nine additional individuals of *C. tancitarensis* with respect to variation in scalation and color pattern, and also on parturition dates, litter size, neonate characters, and food acceptance in captivity.

Methods

All snakes were collected approximately 800 m N of the type locality at Los Portales, Michoacán, México, at 3220 m elevation (coordinates 19°24'13"N, 102°19'45"W) on Cerro Tancítaro. The site is a steep, south-facing slope about 70 × 250 m, covered by grass, herbs, and rocks. The site is bordered to the north by a 3 m high rock wall, to the south by a deep cliff and to the east and west by pine-fir forest, which is the dominant plant formation in the area. Cerro Tancítaro (max. elev. 3900 m) is located in the western portion of the Transverse Volcanic Cordillera. Above 3000 m, the mean annual temperature ranges from 5–12°C, with an average annual rainfall of 1500 mm. Most rain falls from June to October after a 5–6 month dry season (García et al. 2002).

One adult female and two juvenile females were collected on 19 July 2003 between 1400 and 1530 h when the air temperature was 23°C. Another adult female was caught on 29 October 2005 at 1345 h when the air temperature was 19°C. Palpation indicated that the second female was gravid, so it was held in the laboratory until after giving birth to four live and one stillborn neonates on 21 March 2006. All individuals eventually either died or were euthanized and were later deposited in the herpetological collection, Instituto de Investigaciones sobre los Recursos Naturales, Universidad Michoacana de San Nicolás de Hidalgo (INIRENA).

The non-gravid adult female collected in July 2003 (INIRENA 421) was active and the juveniles (INIRENA 414, 423) were coiled under stones. The juveniles were euthanized and preserved immediately after capture. The female was maintained live in a glass vivarium (L50 × W26 × H30 cm) in a laboratory building located at an elevation of 2000 m until she died on 23 November 2006. Ambient temperatures were maintained between 16 and 24°C (mean = 21°C) and laboratory windows provided a natural photoperiod. Room temperature readings were taken every day with a mercury thermometer to the nearest 1°C at 1000 and 1600 h. Basking spots were provided from 1100 to 1500 h, at temperatures between 27 and 30°C, using 50 W incandescent spot-light bulbs. Food acceptance was evaluated by presenting various kinds and life stages of live invertebrates and vertebrates to the adult female INIRENA 421. If food items were not consumed, after 2 h in the case of vertebrates and 24 h for invertebrates, the items were removed from the cage.

The gravid female (INIRENA 560) was found inactive under a stone. The snake was maintained live for five months under the same conditions as described above, until parturition. Of the five neonates (INIRENA 570–575, 3 females and 2 males), the four live ones were maintained in captivity within the same glass terrarium for 60 days. They were maintained at a natural photoperiod with a mean room temperature of 23°C and a range of 18–26°C. Basking spots, as described above, were available every day from 0930 to 1630 h.

Scale counts, body measurements (to the nearest 1 mm using a meter stick), and notes on color patterns follow those described in Klauber (1972) and Campbell and Lamar (2004). Color pattern was recorded from live individuals only, and after the first molt in the case of neonates. Character values from the holotype and two paratypes of *C. tancitarensis* were taken from Alvarado-Díaz and Campbell (2004).

Results and Discussion

Scalation and color pattern.—Table 1 lists character values of the nine specimens reported herein and of the holotype and paratypes of *C. tancitarensis*. The new material conforms well with scutellation and color pattern of type specimens, all the new material expands the range of ventral scale number (from158–160 to 151–160), subcaudal scale number (from 21–22 to 15–22) and dorsal body crossband number (from 49–51 to 48–52). The two males have fewer ventral scales than do females (151 vs. 156–160). Subcaudal scales numbers were 17 and 22 in males (vs. 15–22 in females). Tail length constitutes about 9 and 9.3% of total body length in the two males and 7.5–8.9 % in females. All specimens (including types) exhibit 21 dorsal scale rows at mid-body, a loreal scale that does not contact the lower preocular scale but contacts the supralabial scale series, and a loreal scale that is longer than high (except in INIRENA 414, in which the right loreal is as long as high). Color pattern of the new specimens is similar to type specimens; dorsal ground color pale blue-gray, dark crossbands on body and tail, and a black omega-shaped nape mark. However, neonates and juveniles lacked the pinkish copper-colored stripe along the vertebral line that is exhibited by the types and the other two adults (Fig. 1). Although the range of variation for some characters increased, lepidosis aspects and color pattern of the new material are consistent with the characters that separate *C. tancitarensis* from other members of the *C. intermedius* group (Alvarado-Díaz and Campbell 2004).

Diet in captivity.—During the first two months of captivity, the non-gravid female (INIRENA 421) was offered various types of potential prey, including invertebrates (crickets, mealworms, centipedes), amphibians (*Hyla eximia*, *H. arenicolor*), rodents (newborn mice), and lizards (*Sceloporus grammicus*, *S. aeneus*, *Anolis*

FIG. 1. Adult female (INIRENA 421) and neonates of *Crotalus tancitarensis.*

nebulosus, *Plestiodon copei*). The snake only accepted lizards, consuming all species presented except *A. nebulosus*. Lizard species known to share the local habitat with *C. tancitarensis* include *S. grammicus*, *P. copei*, and *Barisia imbricata*. *Sceloporus grammicus* is the most abundant lizard in the area, so that species is most likely the primary food source of *C. tancitarensis*. Under captive conditions described above, the snake was sustained (until death occurred 41 months after capture) on a diet of adult *S. grammicus* and juvenile *S. aeneus*, at an average feeding rate of one lizard per week.

The gravid female (INIRENA 560) was fed an adult *S. grammicus* about every 10 days after being placed in captivity on 29 October 2005. She stopped feeding in mid February 2006, about one month before parturition. After giving birth on 21 March 2006, she refused all food and died 21 days later.

Neonates refused to eat various types of prey that were similar to those offered to adults, although all vertebrate pretty offered were neonates or juveniles. After 60 days without feeding, one neonate was force-fed a liquefied *S. grammicus*, but died within an hour. The rest of the neonates were subsequently euthanized.

Camarillo and Campbell (2002) reported that captive adult *C. transversus* fed on lizards (*P. copei, S. grammicus, S. mucronatus, S. aeneus*) and mice. They also reported that captive born *C. transversus* neonates refused to eat and eventually died. However, Camarillo and Campbell (1993) earlier reported a neonate *C. transversus* that fed readily in captivity on a diet of *S. grammicus*.

Reproduction.—As mentioned above, the gravid female (INIRENA 560) captured 29 October 2005 gave birth to five young on 21 March 2006. Neonate total lengths ranged from 131 to 150 mm (mean = 143 mm) and they weighed from 2.2 to 3.2 g (mean = 2.7 g). The entire litter weighed a total of 13.7 g, and after giving birth, the mother weighed 20.5 g. When originally captured, the female weighed 40 g, indicating that at time of parturition energy reserves were low. The first molt was on the 10th day postbirth for two neonates and on the 11th day for the other two.

Numerous authors have reported litter sizes of various species of rattlesnakes (see Campbell and Lamar 2004 for a review). Smaller species generally produce fewer offspring (often 5–8) that are relatively large as compared to adults. Conversely, large species produce more young (15–40) that are relatively small as compared to adults. Litter size and relative litter mass recorded herein for *C. tancitarensis* follow this pattern, as do reported litter sizes of other members of the *C. intermedius* group. As examples, a litter of *C. intermedius* from Guerrero consisted of five young

(Armstrong and Murphy 1979), a litter of *C. transversus* from the state of México consisted of four young (Camarillo and Campbell 2002), and litter size for *C. pricei* ranges from 3 to 9 (Campbell and Lamar 2004).

To our knowledge, only five adult *C. tancitarensis* have ever been reported by scientific investigators. Of those, all were females, two are reported for the first time herein, and the three others belong to the type series. Four of the five were collected in summer (June and July) and the other in fall (October). The females collected in summer showed no signs of pregnancy or recent parturition, as would be indicated by flaccid abdomens and longitudinal skin folds on the posterior part of the body (Macartney and Gregory 1988). The sizes of the two juveniles collected in the summer suggest that they were not more than two months old. Therefore, the parturition date of the captive female and the collection date of the two juveniles suggest that the parturition season for *C. tancitarensis* extends from March to July.

Table 1. Measurements (mm) and meristic counts of *Crotalus tancitarensis*. Data for holotype and paratypes from Alvarado-Díaz and Campbell (2004). All adult specimens are female. A = adult, J = juvenile, N = neonate, SVL = snout-vent length, TL = tail length, V = ventrals, S = subcaudals, SL = supralabials, IL = infralabials, PS = scales in the prefrontal region, HL = head length, BC = body dorsal crossbands (exclusive of tail). INIRENA 571 and 575 are males.

* Holotype, ** Paratypes

A number of literature sources have specified parturition dates in rattlesnakes from central and southern México that coincide with the rainy season (see Campbell and Lamar 2004 for a review). The presence of adult females with no signs of reproductive activity during the summer rainy season on Cerro Tancítaro suggests that *C. tancitarensis* has a more-than-annual reproductive cycle (Wharton 1966). The high elevation inhabited by *C. tancitarensis* might also influence reproductive cycles. Other species of Neotropical viperids from highland environments exhibit biennial reproductive cycles (Camarillo and Campbell 2002; Campbell and Solórzano 1992). Additional specimens collected from throughout the year and throughout its geographic distribution are needed to substantiate or refute hypotheses delineating reproductive season in *C. tancitarensis*.

Acknowledgments.—We thank M. Quintero, E. Estrada, R. Valencia, R. Bryson and R. Valencia for their assistance in the field. J. D. Johnson, R. N. Reed and J. A. Campbell provided insightful reviews of an earlier version of this manuscript. A. Quijada and R. Bryson provided advice on the maintenance of rattlesnakes in captivity. This work was supported in part by the Consejo de Investigación Científica, U.M.S.N.H. (project 5.5).

Museum collections are an important source of material for studies of phylogeny, systematics, and phylogeography. These collections can represent rare or extinct species and provide historical samples and may be very useful for genetic studies of reptile populations. The material is usually formalin–fixed and stored in ethanol. Formalin (an aqueous solution of formaldehyde) is the fixative agent most widely used to preserve tissues and organisms, but it causes cross-links in DNA-DNA, DNA-protein and protein-protein (Schander and Halanych 2003; Srinivasan et al. 2002). Several chemical reactions between formaldehyde and nucleic acids have been demonstrated, such as the addition of a hydroxymethyl group (-CH_2OH) in any nucleotide, formation of a methylene bridge between two amino groups, generation of apurinic and apyrimidic sites, and hydrolysis of phosphodiester bonds (Masuda et al. 1999; Srinivasan et al. 2002), causing the break of DNA, mutations and the inhibition of *in vitro* polymerization reactions of nucleic acids. The polymerase chain reaction (PCR) enzymatically amplifies specific sequences of nucleic acids, using very small amounts of DNA as template. In addition to innumerable current applications, PCR also allows nucleic acids from fixed tissues to be used in molecular analyses (Chatigny 2000; France and Kocher 1996; Gioia et al. 1998; Karlsen et al. 1994).

Given that the Herpetological Collection Alphonse Richard Hoge at Instituto Butantan in São Paulo, Brazil has the largest Neotropical collection of snakes with a majority of Brazilian species, we decided to investigate if these formalin-fixed samples are useful for molecular analysis of venom variation. Thus, we studied the crotamine polymorphism of some Brazilian rattlesnakes.

The rattlesnake *Crotalus durissus* occurs throughout most of South America except in Ecuador and Chile. Seven subspecies occur in Brazil: *C. d. cascavella*, *C. d. collilineatus*, *C. d. dryinas*, *C. d. marajoensis*, *C. d. ruruima*, *C. d. terrificus*, and *C. d. trigonicus* (Campbell and Lamar 1989). The venom of *C. d. terrificus* contains four main toxins: crotoxin, convulxin, gyroxin and crotamine (Bercovici et al. 1987). Crotoxin, the most toxic component in *C. durissus* venom, is a neurotoxin with a basic and weakly toxic phospholipase A_2 subunit (Crotoxin B or CB), and an acidic, non-toxic subunit (Crotoxin A, crotapotin or CA) (Hendon and Fraenkel-Conrat 1971). The cDNA precursors of both subunits have been cloned and sequenced. The 5'-untranslated tracts of cDNAs encoding CA and CB are nearly identical and the 3'-untranslated tracts are very similar (Bouchier et al. 1991).

The other major toxic component in *C. durissus* venom is crotamine. Crotamine—a cationic peptide (4.9 kDa, pI 10.8)—translocates into cells *in vitro*, and causes hind limb paralysis and myonecrosis *in vivo* (reviewed in Oguiura et al. 2005). Gonçalves (1956) described a crotamine polymorphism in the South American rattlesnake venoms: the crotamine-positive venoms have the toxin while the crotamine-negative venoms do not. Later, Schenberg (1959) defined two regions in São Paulo state: in the northeastern region he found only crotamine-positive venoms, but in the southwestern region he found predominantly crotamine-negative venoms. Collares et al. (2006) observed that snakes in the northwestern part of Paraná had the highest proportion of crotamine-positive venoms, with the majority of the venoms (71%) having crotamine content more than 10%. Although the individual venom sample sizes varied among the regions, Collares et al. (2006) observed crotamine-positive venoms less frequently in the northern regions including the states of Maranhão and Bahia.

Crotamine-positive rattlesnakes possess the crotamine gene, which is organized in three exons and is located in the extremity of the long arm of chromosome 2 (Rádis-Baptista et al. 2003). The crotamine cDNA of 340-360 base pairs encompasses an open reading frame of 198 nucleotides with 5' and 3' untranslated regions of variable size, signal peptide sequences, and can produce two crotamine isoforms (crotamine and crotamine-Ile19) (Rádis-Baptista et al. 1999). Furthermore, it was demonstrated immunologically that crotamine-negative rattlesnakes do not have crotamine in their venom using (Oguiura et al. 2000) or crotamine mRNA in their venom glands (Rádis-Baptista et al. 1999). Although the crotamine gene is absent in crotamine-negative snake genome, a paralogous crotamine-like gene is present (Rádis-Baptista et al. 2004).

In this work, we present data concerning to the crotamine gene polymorphism in the genome of fixed *C. durissus* subspecies, which are maintained for up to 22 years in the Alphonse Hoge Collection at Instituto Butantan (São Paulo, Brazil), by using PCR and genomic DNA from preserved samples.

Material and Methods

Tissues.—Table 1 indicates the sites where the snakes were collected, their voucher numbers, and their storage time.

DNA.—The DNA was purified using the method described by Ausubel et al. (2000). One hundred milligrams of scraped tissues were washed in TE solution (pH 8.0) for 24 hours at 4°C and then treated at 37°C for 18 h with 0.5% SDS, 10 mM Tris.HCl, 0.1 mM EDTA, 0.1 M NaCl, 0.16 mg/ml Proteinase K and 40 ng/ml RNAse A. The DNAs were purified by phenol/chloroform extraction and

acetate (pH 7)/ethanol precipitation. The DNAs were analyzed by 1% agarose gel electrophoresis in TBE buffer (89 mM Tris; 89 mM boric acid; 25 mM EDTA) and stained with 1 μg/ml ethidium bromide.

Primers.—The crotoxin primers, F crotox (forward): 5'- CCC CTG CCT GGC TTC TCC TTC- 3' and R crotox (reverse): 5'- CCT CAA TCC AGA CCT GGG AA- 3', were synthesized based on cDNA sequences described by Bouchier et al. (1991). The crotamine primers, 5 crot (forward): 5'- CAG TGT CAT AAG AAA GGA GG- 3' and 3 crot (reverse): 5'- CAT CTC CAT CGA CAG TCC AT- 3', were designed based on cDNA sequences described by Rádis-Baptista et al. (1999).

PCR conditions.—The PCR of crotoxin gene was done in 30 μl, using 600 ng of genomic DNA, 6 mM dNTPs, 60 mM $MgCl_2$, 4 pmol of each primer and 1 U of Biotools DNA polymerase and temperature profiles of: 94ºC for 4 min; 40 cycles of 94ºC for 45 sec, 49ºC for 45 sec, and 72ºC for 30 sec. The PCR of crotamine gene was performed in two rounds using 30 μl reaction, and a temperature profile of: 94ºC for 4 min; 25 cycles of 94ºC for 20 sec, 45ºC for 20 sec, 72ºC for 20 sec; and 72ºC for 2 min. In the first round, we used 100 ng of genomic DNA as template and two micro-liters from this first step were added to the second reaction round.

PCR reaction analysis.—Five micro-liters of each amplification product was analyzed in 7.5% polyacrylamide gel electrophoresis (PAGE) in TBE buffer and was stained with 1 μg/ml ethidium bromide.

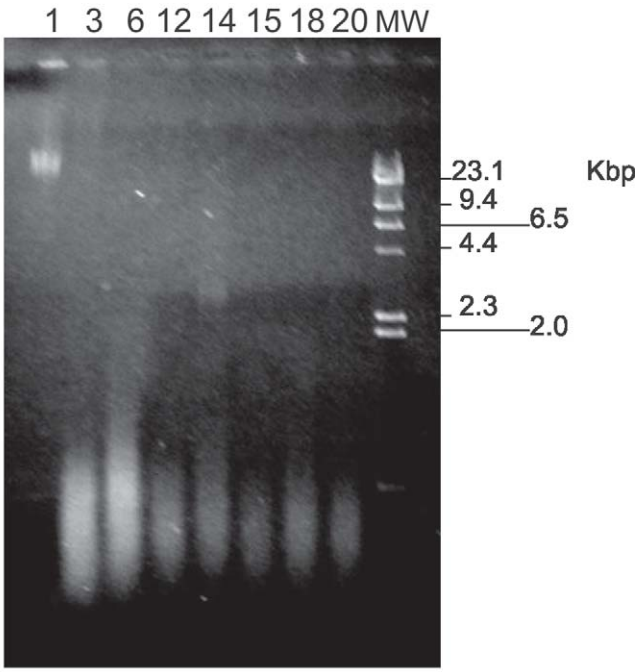

FIG. 1. 1% agarose gel of DNA purified from fresh and fixed tissues. The molecular weight standard (MW) was lambda DNA digested with *Hind* III purchased from Life Technologies.

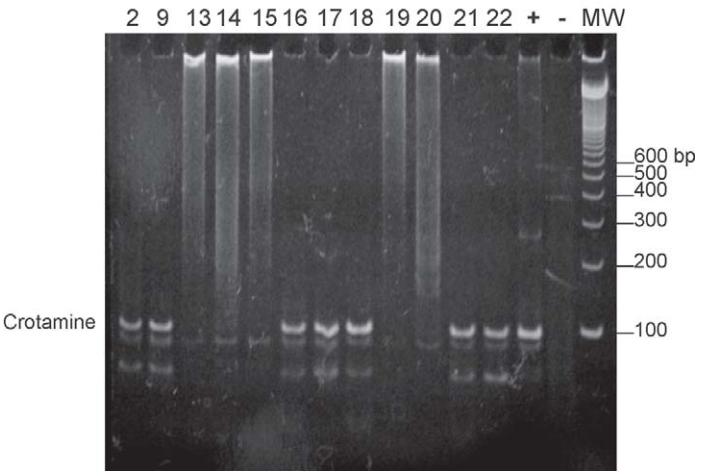

FIG. 2. 7.5% PAGE of PCR of fixed samples, a fresh sample (+), and no DNA (-). The arrow indicates the 100 bp fragment amplified using 5 crot and 3 crot primers. MW is the 100bp DNA ladder purchased by New England Biolabs.

RESULTS

The purification of DNA from fixed tissues took longer to be prepared by proteinase K/SDS method. More amount of proteinase K and longer time of digestion were necessary to disrupt the snake fixed tissue, in comparison to fresh tissues. Even so, a smaller quantity of DNA was obtained from fixed tissues than from non-fixed ones, starting from the same initial amount of material. In addition, the DNA purified from fresh tissue was longer than 23.1 kbp, as indicated in lane 1, Fig. 1, for DNA isolated from blood. Samples 3, 6, 12, 14, 15, 18, and 20 that represent genomic DNA from fixed tissues were markedly degraded, showing DNA lengths of less than 500 bp.

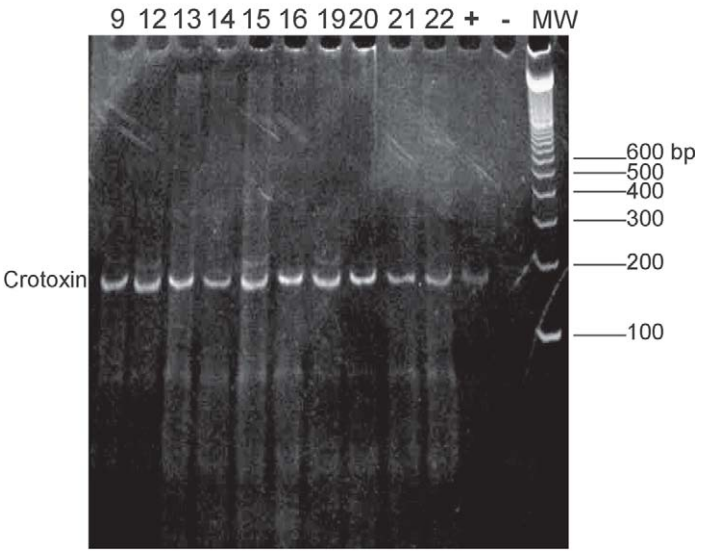

FIG. 3. 7.5% PAGE of PCR of fixed samples, one fresh sample (+) and no DNA (-). The arrow indicates the 200 bp fragment amplified using F-crotox and R-crotox primers. MW is the 100bp DNA Ladder purchased from New England Biolabs.

The PCR product (amplicon) of the crotamine gene was 100 bp long (Fig. 2) while that of the crotoxin gene was 200 bp (Fig. 3). Table 2 shows the PCR results for all the samples. Samples 2, 4, 6, 7, and 10 from the state of Paraná; 8 and 9 from Minas Gerais; 16, 17, and 18 from Maranhão; and 21 and 22 from Bahia were crotamine-positive. On the other hand, samples 5, 11, and 12 from the state of Paraná; 13 and 14 from Minas Gerais; 15 from Maranhão; and 19 and 20 from Bahia were crotamine-negative. As expected, all the samples have the crotoxin gene amplified, since all *C. durissus* in Brazil contain this neurotoxin in their venom. We observed some smear and faint bands in crotamine gel that are non-specific amplifications probably appeared in function of the high number of cycles used, more than 50 in polymerase chain reaction (double PCR reaction).

DISCUSSION

As it may be widely known, formalin fixation imposes a harsh condition of tissue preservation that damages nucleic acids inside the cells, despite its powerful ability to keep the intact structure of any preserved tissue. Huge collections of animals and plants that are potentially useful for studies of the molecular history of such organisms along space and time are kept in museums. For example, the Alphonse Richard Hoge Collection at Instituto Butantan (São Paulo, Brazil), contains over 70,000 catalogued Neotropical snake specimens, some of which are up to 100 years old.

Here, using PCR and specific primers, two genes encoding toxic components of rattlesnake venom (crotoxin and crotamine) were successfully amplified from genomic DNA extracted from formalin-fixed snake specimens. We were able to amplify the majority of DNA tested (approx. 90% of all samples), even in conditions of snake fixation that are not ideal for use in molecular biology protocols.

The low yield of DNA purified from formalized tissues may have resulted from the loss of low molecular weight (LMW) nucleic acid sequences that bind to proteins. During phenol treatments, it is possible to diminish the loss of DNA linked to protein by using DTE (dithioerythritol) or DTT (dithiothreitol) in extraction buffer, because these reducing agents break the cross-links between DNA and protein (Chatigny 2000; Schander and Halanych 2003). It is also possible to improve the recovery of LMW DNA during nucleic acid precipitation using carriers such as tRNA or glycogen (De Giorgi et al. 1994). The links between DNA-protein and DNA-DNA can also be broken by heating the DNA from fixed tissue in TE at 70°C, which improves the DNA yield (Masuda et al. 1999).

Even though the sizes of recovered genomic DNA samples were around 500 bp, they were useful for the molecular analysis of crotamine gene polymorphism and for accessing the presence of crotoxin gene. This is because the amplicons' size we were investigating lie between 100 and 200 bp. In fact, the lengths of amplicons in the PCR of genomic DNAs from fixed and fresh tissues were identical (that is, 100 bp) when using primers for crotamine gene (5 crot and 3 crot) and 200 bp when using crotoxin-specific primers (F crotox and R crotox). Both gene fragments were amplified from a single exon: exon II, in the case of crotamine, and the 5'-untranslated region of CA which is identical in CB, in the case of crotoxin. The crotamine gene polymorphism is well

TABLE 2. PCR of **CRO** – crotamine sequence and **CTX** – crotoxin sequence that resulted in amplification (+), no amplification (-) and not tested (**NT**).

known among herpetologists: crotamine-negative rattlesnake have neither crotamine transcripts in their venom gland nor crotamine in their venom.

Our molecular results on fixed samples are consistent with the expected pattern of crotamine distribution. For example, Itapagipe and Pouso Alegre cities are in a region described as a mixed one, where both varieties are found, in the south-central region of Minas Gerais state (Bicalho et al. 1990). In the northwestern region of Paraná, including Cianorte and Tapejara, the rate of crotamine-positive venoms is high (Schenberg 1959), Crotamine was also detected in some venoms from Bahia it was using immunological method in a venom from Ibiquera (Collares et al. 2006). On the other hand, crotoxin is an ubiquitous toxin that is expressed in all *C. durissus* venom, independent of the local where snake are found. So, as expected all genomic DNA samples have the crotoxin gene fragment amplified, what worked as a positive control of PCR reaction. Lung tissue proved not to be useful because of the false negative result of sample 5.

In a parallel experiment, the PCR results of samples 2 to 14 were confirmed using DNA taken from the frozen livers from the same animals (data not shown). The amplification of gene sequences from genomic DNA isolated from fixed tissues posed greater difficulties than from fresh ones, since a larger amount of template was required to amplify the crotoxin sequence. Moreover, this was particularly true in the amplification of crotamine gene, for which an extra PCR round was carried out when compared with the PCR conditions routinely used in our laboratory, i.e., 100 ng of genomic DNA and 30 cycles. However, even in these circumstances, the formalin-fixed snakes constitute a valuable source to investigate the natural history of these animals and the correlation with their respective toxic traits.

Crotalus durissus terrificus is the predominant rattlesnake subspecies found in Brazil. In addition to it, we tested two subspecies, *C. d. marajoensis*, and *C. d. cascavella*, whose crotamine polymorphism has been little studied. *C. d. marajoensis* occurs in northern Brazil (Ilha de Marajó, Pará) and *C. d. cascavella* in northeastern Brazil (states of Maranhão, Piauí, Ceará, Rio Grande do Norte, Paraíba, Pernambuco, Alagoas, Sergipe, and Bahia). Although the venoms of rattlesnakes from the states of Bahia, Pernambuco, Piauí, and Maranhão are believed to be crotamine-negative (Santoro et al. 1999, Toyama et al. 2005), we detected the crotamine gene in *C. d. cascavella* from São Luiz (Maranhão) and from Ibiquera and Grajaú (Bahia). Dr I. Biondi also observed the effect of some crotamine-positive venoms from Bahia in mice which showed myonecrosis in hystological preparations from muscles (personal communication). Our findings therefore indicate not only that these specimens tested positive for crotamine gene but also that these populations of *C. d. cascavella* contain crotamine-positive individuals. The only *C. d. marajoensis* snake we tested was crotamine-negative. Interestingly, this is the first time that crotamine has been detected in the rattlesnake *C. d. cascavella* inhabiting the northeastern regions of Brazil, encompassing the states of Bahia and Maranhão. Thus, in addition to molecular analysis by northern and southern blot and immunological approaches like ELISA, PCR of fixed tissue appears to be a useful method to study venom variation in preserved rattlesnakes obtained from museum collections.

In conclusion, this study demonstrated that PCR is a reliable technique for detecting crotamine and other toxin genes, and to analyze their distribution among population of snakes without using the snake venom itself. This is valid for the investigation of genomic DNA isolated from fresh tissues, as well as from fixed specimens.

Acknowledgments.—To Fundação de Amparo à Pesquisa de Estado de São Paulo (FAPESP) for its financial support of this work, and to FUNDAP for the fellowship granted to Poliana G. Corrêa. We are also indebted to K. F. Grego for his help in handling and caring for the snakes and to H. Suzuki for providing the frozen tissues and suggesting improvements to the manuscript.

The Effectiveness of Fluorescent Powdered Pigments as a Tracking Technique for Amphibians

GABRIELLE J. GRAETER*

University of Georgia, Savannah River Ecology Laboratory
Drawer E, Aiken, South Carolina 29802, USA

**Corresponding author e-mail: graeter@srel.edu*

Researchers often use thread-trailing devices or radio-telemetry to study amphibian movement and terrestrial habitat use (Madison and Farrand 1998; Schwarzkopf and Alford 2002; Sinsch 1988; Tozetti and Toledo 2005; Watson et al. 2003). However, small size and sensitive skin can make these methods problematic, if not impossible, for some amphibian species or life stages. Fluorescent powdered pigments are useful for obtaining detailed information about short-term movement, behavior, and microhabitat use of other animals, including mammals (e.g., Lemen and Freeman 1985; Mullican 1988), reptiles (e.g., Blankenship et al. 1990; Dodd 1992; Stark and Fox 2000), and insects (e.g., Johansson 1959; Sujii et al. 2000). More recently, they have been used to track the terrestrial movements of amphibians (Birchfield and Deters 2005; Eggert 2002). Using fluorescent powder to track amphibians has several advantages, including being relatively inexpensive, harmless to amphibians (Rittenhouse et al. 2006), and suitable for use on juveniles and small species.

Powder tracking is becoming recognized as an underutilized amphibian tracking method that has great potential and may be the preferred method under certain circumstances (Birchfield and Deters 2005; Rittenhouse et al. 2006). However, the effectiveness of this method across amphibian taxa and under varying field conditions has not been evaluated. We present data from three species, the Marbled Salamander (*Ambystoma opacum*), Southern Toad (*Bufo terrestris*), and Southern Leopard Frog (*Rana sphenocephala*), to evaluate the potential strengths and limitations of powder tracking as a technique for amphibians. Our results shed light on the relative distances different species can be tracked with powder, the influence of precipitation on detectability of path length, and the effectiveness of different powder colors. This evaluation of fluorescent powder tracking as a technique has been extracted from a habitat and movement study by Graeter (2005) that is part of a larger experimental study called LEAP (Land-use Effects on Amphibian Populations).

Materials and Methods.—We released 44 adult *A. opacum* (February–March 2005; 22M, 22F), 36 adult *B. terrestris* (March–May 2005; 28M, 8F), and 48 adult *R. sphenocephala* (May–August 2004; 25M, 19F) on forest-clearcut edges at three LEAP sites (named 37, 119, and 1000) on the Savannah River Site (SRS) in the Upper Coastal Plain of South Carolina, USA (see Graeter 2005 for details). The forests were predominantly *Pinus* species (e.g., Longleaf, Loblolly, Slash Pine), but had hardwoods interspersed throughout (e.g., oak, maple, hickory, dogwood, sweetgum). Ten-acre clearcuts were created in the spring of 2004. At the time of this study, clearcuts had patches of resprouting hardwoods, bare soil, and scattered piles of woody debris.

We collected *A. opacum* and *B. terrestris* at drift fences encircling wetlands at LEAP sites 37 and 119, and released each animal within approximately 100 m of its capture location. Because our study sites did not have breeding populations of *R. sphenocephala*, we collected frogs from a wetland >15 km from the two LEAP sites (37 and 1000) where they were released, a distance at which there is no evidence for homing of ranids (Dole 1968). Body size (mean snout–vent length ± SD) was 57 ± 3 mm for *A. opacum*, 56 ± 6 mm for *B. terrestris*, and 65 ± 6 mm for *R. sphenocephala*.

Prior to release, we applied fluorescent powder (US $12/lb, Radiant Color Series T1, Richmond, California; now DayGlo Color Corporation, Cleveland, Ohio) to each individual by dipping the rear 2/3 of its body into powder until the skin was thoroughly covered. We were careful to prevent powder from coming in contact with the animal's eyes or mouth. The handling time was kept to less than 30 seconds per individual, and all releases took place just after dark. To give them sufficient time to move, we returned approximately 24 h after release and tracked the path of each individual using a Portable Rechargeable UV Lamp (UVL-26P, Fisher Scientific, Hampton, New Hampshire) until we either located the animal or could not find any more powder. We used a Global Positioning System (GPS) Trimble Pro-XR backpack unit with submeter accuracy to record each path from start to end. We then downloaded the GPS data and used the Animal Movement extension (Hooge and Eichenlaub 1997) in ArcView 3.3 (Environmental Systems Research Institute, Redlands, California) to calculate the detected path length for each individual. We recorded daily rainfall (All-Weather Rain Gauge, Forestry Suppliers Inc.), percent relative air humidity (Bacharach Pocket-Size Sling Psychrometer, Forestry Suppliers Inc.), and percent soil moisture (TH_20 Soil Moisture Meter, Dynamax Inc., Houston, Texas); humidity was recorded approximately 0.5 m off the ground and soil moisture was taken in the top 8 cm of soil.

We tested the effects of powder color, species (*A. opacum, B. terrestris, R. sphenocephala*), and the interaction of species and powder color on path length using a two-way ANOVA (Proc GLM, SAS Institute 2000). We used Type III sums of squares because we had unequal sample sizes and Tukey-Kramer's test to determine which colors differed from each other. We also assessed the effects of post-release precipitation on mean and maximum detected path length for each species. For this analysis, we categorized rainfall into precipitation classes: 0 mm, light (< 10 mm), and heavy (> 10 mm). Because there was no precipitation after releases of *B. terrestris*, we could not examine the effects of rainfall on path length for this species.

Results.—Path length differed among the three species ($F_{species\ 2,114} = 16.81$, $P < 0.0001$). The mean detected path length after 24 h was shortest for *A. opacum* and longest for *R. sphenocephala* (Fig. 1). The minimum distance an individual traveled was similar among the three species (1.9–3.5 m). Detected path length also varied among powder colors ($F_{color\ 3,114} = 2.36$, $P = 0.0757$; Fig. 2a). Chartreuse paths were longer than pink paths ($P = 0.0937$, Tukey-Kramer test). Path length did not differ among powder colors for *A. opacum*; however, chartreuse paths tended to be longer than other colors for both *B. terrestris* and *R. sphenocephala* (Fig. 2b). The interaction between species and powder color was not significant ($F_{species*color\ 6,114} = 1.02$, $P = 0.4157$).

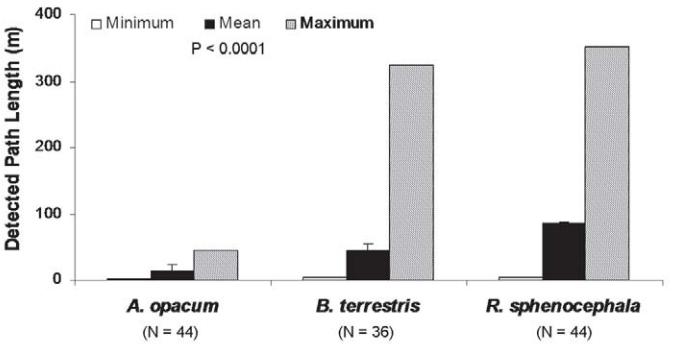

FIG. 1. Minimum, mean (± 1 SE), and maximum detected path lengths of *Ambystoma opacum*, *Bufo terrestris*, and *Rana sphenocephala* in South Carolina (24 h post-release).

The amount of post-release rainfall affected the detectability of path length. Light amounts of precipitation (< 10 mm/day) did not make detection of powder more difficult (Fig. 3). However, heavy rainfall (> 10 mm/day) tended to decrease the mean detected path length for *R. sphenocephala* (mean path length = 54.5 m for > 10 mm vs. 79.7 m for 0 mm). Most importantly, the maximum detected path length for *R. sphenocephala* was greatly reduced by heavy rains (77.0 m for > 10 mm vs. 178.7 m for 0 mm; Fig. 3a). Shorter paths, such as those created by *A. opacum*, were not affected by light rainfall (Fig. 3b). We observed that paths remained mostly intact for 1–2 days after the release when there was no precipitation. We could discern whether an individual had rested

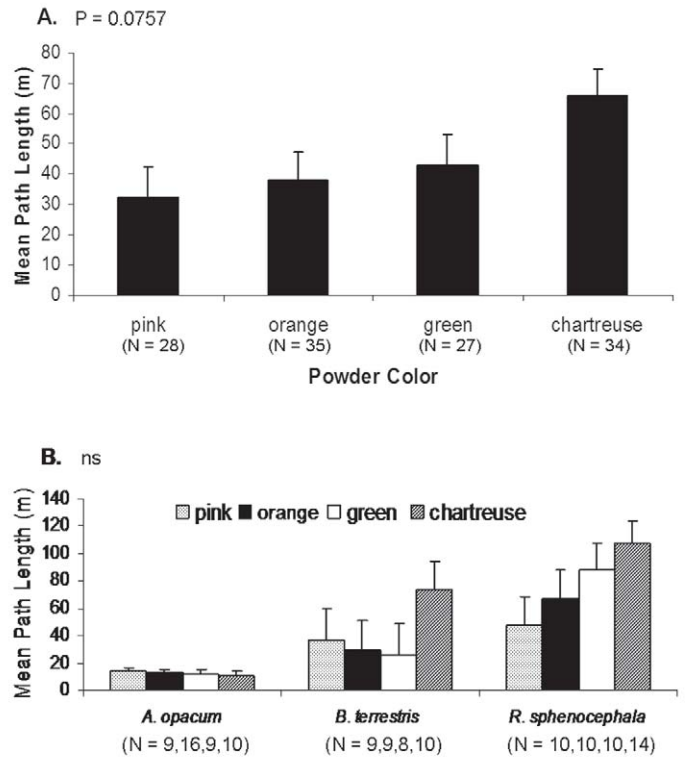

FIG. 2. Detected path length (mean ± 1 SE) for (A) the powder color and (B) powder color specific to species. Chartreuse paths were longer than pink paths ($P = 0.0937$).

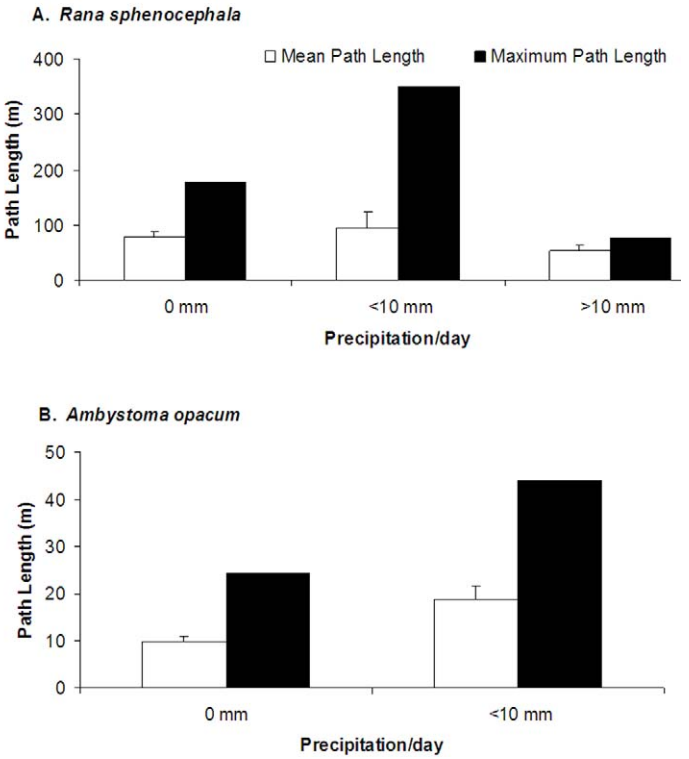

FIG. 3. Relationship between post-release precipitation per day and mean and maximum detected path length in (A) *Rana sphenocephala* at three different precipitation levels and (B) *Ambystoma opacum* at two different precipitation levels. No rainfall > 10 mm was recorded during the *A. opacum* releases, thus, that category is not included.

on woody debris or moved under it, the type of vegetation it had traveled through or avoided, and what type of cover it selected. The percent relative humidity and percent soil moisture (mean ± 1 SE), respectively, were 82.05 ± 1.31 and 19.90 ± 0.93 during the *A. opacum* trial, 67.03 ± 1.43 and 16.14 ± 1.22 during the *B. terrestris* trial, and 84.06 ± 1.12 and 10.36 ± 0.73 during the *R. sphenocephala* trial.

Discusssion.—Fluorescent powder tracking can be used successfully with a broad range of amphibian taxa, but the effectiveness of the technique depends greatly on a species' movement patterns and the environmental conditions. We found that amphibians can be tracked long distances (> 350 m) within a 24 h time period under ideal conditions (i.e., dry ground, little or no precipitation, and when movement is on the surface). However, some colors are more difficult to detect than others (Birchfield and Deters 2005; Stark and Fox 2000). The effect of powder color on path length was only evident for the relatively long paths we obtained with *B. terrestris* and *R. sphenocephala*. As path length increased and the flecks of powder became infrequent along the path, certain colors became more difficult to detect than others. Chartreuse and green paths were easiest to detect, followed by orange and then pink. With relatively short path lengths or slow-moving animals (e.g., *A. opacum*), the powder trails were heavy and color had little effect on detectability, as found in previous studies (Birchfield and Deters 2005). Although detectability varies by color, this is not an issue unless animals travel long distances. Some powder colors (e.g., pink and orange, chartreuse and green) are difficult to differentiate under UV light (Birchfield and Deters 2005; Stark and Fox 2000). However, this problem could often be remedied through close examination of the specks of powder under a white light.

Fluorescent powder, while non-toxic, is fairly persistent in the landscape (Halfpenny 1992), particularly if there is little moisture or precipitation. Thus, if movements are concentrated within a small area, it can be difficult to follow the path when powder trails cross and a heavy rainfall will be necessary before powder of the same color can be used again (Stark and Fox 2000). Although specks of powder sometimes remained visible for weeks, even after a heavy rain, the paths themselves were not discernable for more than a few meters. In situations where paths are unlikely to overlap (e.g., individuals are being tracked in separate locations) and only one powder color is needed, chartreuse may be the optimum color to use.

This technique is most effective in answering questions about fine-scale movement and microhabitat use because paths usually persist only 1–2 days after application. To answer long-term questions, powder could be reapplied, but rehandling and reapplication have the obvious disadvantage of influencing the animal's behavior. Recapturing individuals for reapplication is likely to be most effective when the study species is not moving long distances (e.g., *R. sphenocephala*, this study) or burrowing deep underground (e.g., some *A. opacum* in this study).

In other studies that have used fluorescent powder to track amphibians, path lengths were similar to the values and ranges presented here. For example, adult ringed salamanders (*A. annulatum*; tracked 3 h post-release; N = 60) and wood frogs (*R. sylvatica*; tracked 4 h post-release; N = 10) were tracked using fluorescent powder at LEAP study sites in Missouri and Maine, respectively, (C. Conner and S. Blomquist, unpubl. data). The mean detected path length for *A. annulatum*, at 36.9 m (range: 2.4–133.8 m), was slightly longer than the mean path length of *A. opacum*, indicating that this technique has the potential to be equally successful with two closely related species in different geographic regions. *Rana sylvatica* had a much shorter mean (10.4 m) and maximum (27.3 m) detected path length relative to *R. sphenocephala* and *B. terrestris* (this study), and this may have been due to wet ground conditions at the Maine site (S. Blomquist, unpubl. data). In another study, the mean path length of green frogs (*R. clamitans)* on golf courses in Missouri was 19.1 m (range: 4.7–33.9 m) when the frogs were given 1–3 h in which to move (Birchfield and Deters 2005). Likewise, in France, spadefoot toads (*Pelobates fuscus*) were tracked 17.0 m on average (range: 3.1–73.0 m) approximately 24 h after release (Eggert et al. 1999); these distances are well within the range of the species we studied. Eggert (2002) attributed the short movement distances of *P. fuscus* to their relatively small size and locomotory behavior (e.g., frequent burrowing, short daily movements, walking rather than jumping).

Just as powder works better for tracking some lizard species than others because of their scale type (Dodd 1992; Stark and Fox 2000), differing skin types and body sizes in amphibians may affect how well and how much of the powder clings to the skin, and thus, the efficacy of this technique. For example, powder may stay on *B. terrestris* better than *A. opacum* because *B. terrestris* has more surface area and uneven skin to which powder clings. However, by observing some individuals over multiple days we know that within 1–2 days, the majority of the powder had usually

brushed off the amphibians, such that only small remnants of powder were still visible on their skin. In a laboratory setting, where there was less opportunity to brush the powder off on natural objects (Rittenhouse et al. 2006), amphibians lost powder at a rate comparable to what we observed.

We found that certain techniques improved application and retention of the powder. Like many salamanders, *A. opacum* squirmed while being handled, causing the powder to wipe off; thus, we suggest minimizing handling time and keeping the powder in a small plastic container to ease application. *Rana sphenocephala* also can be difficult to handle so we advise holding the frog by its front legs with its snout in the palm of your hand while applying powder. Lastly, the powder clung best to *B. terrestris* if loose soil was brushed off and the animal's skin was slightly moist.

The success of this technique also can be influenced by the behavior of the study species. For example, if the study species spends time in an aquatic or moist environment (e.g., *R. sylvatica* in Maine, also Eggert 2002) or burrows underground (e.g., *A. opacum*, also see Eggert 2002), it will be more difficult to track them with powder. Likewise, species that move closer to the ground (e.g., *A. opacum*) may rub off more powder per distance traveled than those that hop (e.g., *R. sphenocephala*). Additionally, powder tracking will likely be most effective for pond-breeding amphibians if used during the non-breeding season at times when some surface activity is exhibited.

Others have suggested that precipitation reduces the visibility of powder trails or even obliterates them entirely (Blankenship et al. 1990; Lemen and Freeman 1985), but the relationship between rainfall and the detectability of path length of amphibian powder trails has not previously been evaluated quantitatively. We found that fluorescent powder trails made by amphibians persisted under light rainfall, but the detected path length was shortened considerably by rainfall > 10 mm. Likewise, light rainfall did not seem to affect the maximum detected path length of *R. sphenocephala*, but heavy rainfall tended to truncate the maximum path length, thus demonstrating that fluorescent powder tracking can be successful even with some precipitation. However, South Carolina is relatively dry (mean annual rainfall on SRS 1973-2003: 124.5 cm; Hunter 2004) and what we have termed heavy rainfall is likely considered light in other regions. Therefore, local and regional weather conditions should be carefully considered in deciding whether to use this technique. In areas where field conditions are typically moist, powder tracking may not be as informative or useful as it is in drier regions.

This technique has several advantages relative to other tracking techniques, such as radio-telemetry and thread-trailing, including that it is harmless to the animal (Rittenhouse et al. 2006) and can be used on juveniles and small species because a tracking device is not attached or inserted. Additionally, powder tracking is inexpensive relative to radio-telemetry and can yield high sample sizes due to the low intensity of the work. Nonetheless, when a study involves tracking for long periods of time and following movement in aquatic or subterranean habitats, other techniques may be more effectively employed.

Acknowledgments.—We thank S. M. Blomquist and C. A. Conner for generously providing data on fluorescent powder tracking from the Maine and Missouri LEAP sites. We are grateful to D. S. Berry, S. E. DuRant, J. W. Gibbons, A. D. Green, M. Langley, T. M. Luhring, J. P. Nestor, J. D. Willson, C. T. Winne, and M. S. Wright for field assistance, and R. Baldwin, S. M. Blomquist, C. R. Carroll, C. A. Conner, M. C. Freeman, J. W. Gibbons, D. Olson, J. D. Willson, and an anonymous reviewer for providing useful comments on the manuscript. This study was funded by the National Science Foundation (Award DEB 0242874). Research and manuscript preparation were aided by the Environmental Remediation Sciences Division of the Office of Biological and Environmental Research, U.S. Department of Energy through Financial Assistance Award DE-FC09-96SR18546 to the University of Georgia Research Foundation. The procedures used in this study were approved by the University of Georgia animal care and use committee (A2003-10024, "Reptile and Amphibian Research—General Field Studies") and the South Carolina Department of Natural Resources (collection permits: 56-2003, 07-2004).

Recently, several studies have attempted to develop methods for sampling aquatic or semi-aquatic amphibians and reptiles with minimal observer bias. Field experimentation has included devising and testing novel aquatic traps (Mushet et al. 1997; Richter 1995), and assessing efficacy of commercially-available aquatic traps (Buech and Egeland 2002; Casazza et al. 2000; Johnson and Barichivich 2004; Willson and Dorcas 2004; Willson et al. 2005). Trapping for amphibians has generally been directed towards larvae, a combination of larvae and breeding adults, or aquatic species. However, none of these studies sufficiently addressed our objective to determine which commercially-available funnel trap best samples relatively large (9–15 cm SUL [snout–urostyle length]) ranid frogs in aquatic habitats.

To evaluate the effectiveness of traps to capture ranids, we compared two commercially-available funnel traps having large-diameter interior funnel openings. These included 79 cm × 23 cm cylindrical, 6 mm galvanized steel mesh traps (steel trap) with interior funnel openings 5.5 cm in diameter (model G40CF, Cuba Specialty Manufacturing Company, Fillmore, New York) and 43 cm × 23 cm rectangular, 3 mm nylon mesh traps (nylon trap) having interior funnel openings 5 cm in diameter (model RN10, Memphis Net and Twine Co., Inc, Memphis, Tennessee). To allow traps to rise and fall with water levels, two polystyrene floats were attached to the interior, middle, and opposing sides of each trap with plastic cable ties (steel trap floats were 22.5 cm × 5 cm × 5 cm, nylon trap floats were 22.5 cm × 5 cm × 2.5 cm). Floats were attached to the interior of traps to reduce the likelihood of damage to or loss of floats, and to permit placement of traps directly against drift fences to maximize the probability of frogs encountering traps. Traps floated low enough in the water to completely submerge their interior funnel openings, yet high enough to provide trapped animals access to air.

Trap efficiency was tested in two aquatic habitats in Jackson and Union counties, Illinois between 30 August and 7 October 2005. Trap Site One (TS1) was a 0.1 ha human-made pond in Giant City State Park. Water depth (> 1 m) limited aquatic vegetation (common cattail [*Typha latifolia*] and cutgrass [*Leersia* sp.]) to within 3 m of the bank. Trap Site Two (TS2) was a shallow-water (< 0.45 m), 1.74 ha constructed wetland on private property. Wetland vegetation, which covered > 95% of the inundated portion of the basin, included Water Primrose (*Jussiaea repens*) and Waterthread Pondweed (*Potamogeton diversifolius*). During sampling, water covered half the basin.

At TS1, 20 pairs of traps were set 3 m apart within the nearshore vegetation along half the shoreline. Each trap pair included one steel trap and one nylon trap, 0.5 m apart, set parallel to the bank in water deep enough to inundate the interior openings of each trap. The type of trap was alternated at successive stations to eliminate possible bias associated with trap location relative to shore and water depth. For example, at trap station 1 the nylon trap was closer to shore than the steel trap, at trap station 2 the steel trap was closer to shore than the nylon trap, etc. Each trap was checked daily from 31 August–9 September 2005 (400 trap-nights). Captured frogs were marked for individual recognition by toe-clipping before releasing them into the water within 0.5 m of their point of capture. To prevent cross-contamination and infection, scissors were dipped in isopropyl alcohol between each use.

At TS2, traps were set along aquatic drift fences. Nine, 10-m long × 0.6-m high drift fences were constructed from 0.6-cm black polyethylene mesh by attaching the mesh to 1.5-m tall steel fence posts with plastic cable ties. The mesh extended from the substrate to an average of 0.4 m above the water surface. The fences were installed approximately 30 m apart, 2.5–19.5 m (mean = 6.25 m) from shore, and bordered approximately 25% of the shoreline. A steel trap and a nylon trap were paired on opposite sides of each end of every fence. Each fence had a shore-side steel trap and nylon trap, as well as a pond-side steel trap and nylon trap (four traps per fence). Traps were set between the fence and a pair of 1.5-m long, 1.2-cm diameter galvanized-steel pipes sunk vertically into the substrate. Each trap was loosely attached to the pipes with plastic cable ties to keep traps adjacent and parallel to the fence while allowing them to float up and down with fluctuations in water level. Traps were opened prior to predicted rain events and closed within 1–2 days. Trapping during rain events increased the likelihood of capturing Southern Leopard Frogs (*Rana sphenocephala*) which sometimes breed during fall rains in southern Illinois (Petzing and Phillips 1999). Traps were closed by fitting 0.26-L plastic cups into each funnel opening. Frogs were trapped for 11 nights during five trapping periods (15–17 September, 18–21 September, 25–27 September, 28–30 September, 5–7 October 2005) for a total of 396 trap-nights. Each captured frog was batched-marked by cutting the longest toe on the left hind limb.

Excluding recaptures, we captured 38 American Bullfrogs (*Rana catesbeiana*) and 60 Green Frogs (*Rana clamitans*) at TS1, and 211 *R. catesbeiana*, 12 *R. clamitans*, and three *Rana sphenocephala* at TS2 (Fig. 1). Our assumption of equal trap efficacy was tested by using chi square goodness-of-fit analyses (Sokal and Rohlf 1995). Both trap types were equally effective at capturing *R. catesbeiana* ($\chi^2 = 1.68$, df = 1, P = 0.194), *R. clamitans* ($\chi^2 = 0.6$, df = 1, P = 0.439), and both species combined ($\chi^2 = 0.408$, df = 1,

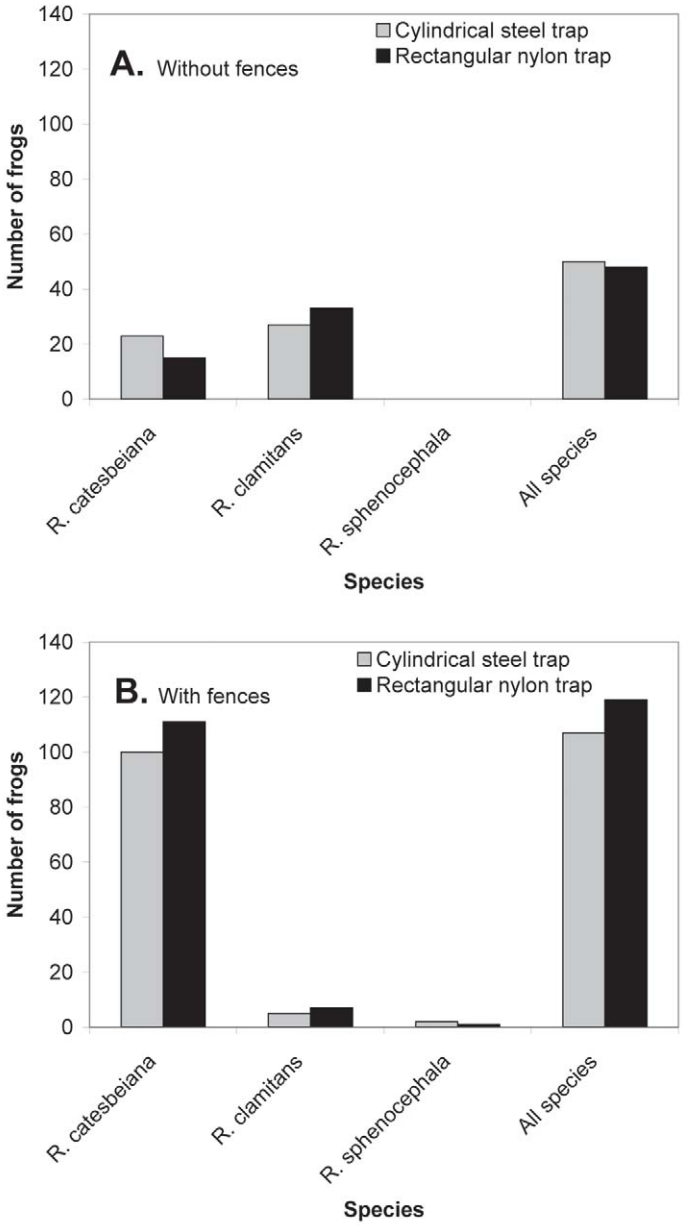

FIG. 1. Total capture of ranid frogs in cylindrical steel traps and rectangular nylon traps placed at study site TS1 without drift fences (A), and study site TS2 with drift fences (B).

P = 0.84) at TS1 and *R. catesbeiana* ($\chi^2 = 0.573$, df = 1, P = 0.449) and all frogs combined ($\chi^2 = 0.637$, df = 1, P = 0.425) at TS2. Although most frogs captured were young-of-the-year (93.9% at TS1 and 95.1% at TS2), traps did yield 12 subadult-adult *R. catesbeiana* (6 per trap type) ranging from 9–14 cm SUL.

Eight *R. catesbeiana* and four *R. clamitans* were recaptured once each at TS1, with most (83.3%) frogs being captured in one trap type then recaptured in the other. At TS2, we recorded eight recaptures (all *R. catesbeiana*). Trap mortality was low (1.0% at TS1, 0.4% at TS2) and appeared to be the result of invertebrate predation. One *R. clamitans* was killed by a fishing spider (*Dolomedes* sp.) and one *R. catesbeiana* was a casualty of crayfish (*Orconectes* sp.) predation.

Despite homogeneous shoreline habitat at both sites, the number of frogs captured at individual trap stations ranged from 1–10 at TS1 and from 15–41 at individual drift fences at TS2. Unequal catch along the shoreline suggests frogs were distributed non-randomly. Non-random distribution of frogs along the shoreline could influence results when using funnel traps, either alone or in conjunction with drift fences, to estimate frog abundance. The use of numerous traps or drift fences along as much shoreline as possible may compensate for location bias in studies designed to estimate population size. However, unequal capture probabilities along the shoreline can hamper interpretation of trapping results even when using large numbers of traps (K. Dodd, pers. comm.).

In summary, both trap types are equally effective for capturing ranid frogs. Nylon traps, however, are less durable than steel traps (Willson et al. 2005). Three nylon traps required repair (e.g., zippers broke) and two were rendered unusable following attempted predation of trap contents by a Snapping Turtle (*Chelydra serpentina*). In addition, nylon traps were more harmful to trapped animals; more frogs in nylon traps than steel traps rubbed surficial layers of skin from their snouts while attempting to escape.

Acknowledgments.—We gratefully acknowledge funding provided by the Strategic Environmental Research Development Program. We thank Dan Woolard and Bob Martin for permission to use the pond in Giant City State Park, and Brenda and Merv Tripp for permission to use their wetland. We also thank Ellen Starr for facilitating the use of the Tripp wetland; and Ken Dodd, Jr., John Willson, and two anonymous reviewers for comments on the manuscript. Animals collected for this project were handled using approved Oak Ridge National Laboratory Animal Care and Use Committee protocols, which address animal care policies specified in Public Health Service, USDA, and the Animal Welfare Act regulations. Funnel traps of various designs have been used to capture adults and larvae of aquatic amphibians (e.g., Buech and Egeland 2002; Richter 1995). Most studies use unbaited funnel traps to capture amphibians while others have used shrimp or salmon eggs (Adams et al. 1997). Light traps and light sticks are commonly used in studies of fish, particularly larvae (Doherty 1987; Marchetti et al. 2004), but have not been widely used to capture amphibians. Glow sticks have been mentioned briefly in the literature as a means to increase capture rates of aquatic amphibians (Smith and Rettig 1996), but no studies have estimated their effectiveness. In this study we compared the capture success of unbaited funnel traps and funnel traps baited with glow sticks.

We used commercially available plastic minnow traps (similar to Challenge Plastic Products #50176) to capture eastern red-spotted newts (*Notophthalmus viridescens*) in Station Pond at Mountain Lake Biological Station (MLBS) in Giles County, Virginia. Station Pond is a 0.65 ha stream-fed permanent pond constructed in 1965. One hundred and four minnow traps were used to capture aquatic adult *N. viridescens* as part of a larger project to estimate the population size of newts in the pond. We used Pollock's robust design for our sampling regime (Pollock 1982), with eight sampling occasions divided into four primary periods with two secondary sampling occasions per primary period (Table 1), so the data could be used in a capture-recapture study reported elsewhere. Trap locations were randomly assigned to receive a glow stick or remain empty on the first sampling occasion and were switched to the other treatment for the subsequent primary period. Therefore, fifty-two randomly selected traps contained glow sticks for sampling occasions 1, 2, 5, and 6 (primary periods 1 and 3) and the other fifty-two contained glow sticks for sampling occasions 3, 4, 7, and 8 (primary periods 2 and 4). This design was chosen to maintain consistent conditions within a primary period, a requirement for Pollock's robust design, and to account for spatial and temporal effects in capture efficiency.

Sixty-four minnow traps were placed around the perimeter of Station Pond with 4–4.5 m between each trap. Traps were attached to a length of rope, tied to a PVC stake on the bank, and alternated between being placed 1 meter and 2 m from the bank. Forty traps were placed in a grid in the middle section of the pond using a row boat. A foam float tied to a rock using string noted the location for each trap. A second string for the trap was attached to each foam float with a fishing stringer tied to the end of the string for ease of placement and removal of traps. Therefore, every trap was in approximately the same location for each sampling occasion.

For each sampling occasion traps were placed in the pond from 1900–2000 h. A small rock was placed in each trap so it rested on the substrate of the pond. Traps were removed from 0800–1000 h the following morning and *N. viridescens* were counted and sexed. The number of tadpoles captured was also recorded.

The glow stick treatment traps were baited with non-toxic yellow bracelet-sized glow sticks (Glow Universe, US $9.49 per 100; 20.32 cm length, 0.5 cm diameter, 6–8 h glow time). We chose thinner bracelet-sized glow sticks to avoid catching more individuals than could be handled in one day due to the large number of traps. Glow products, which are widely available and normally used as novelty jewelry, come in several sizes and our preliminary trapping indicated thicker glow sticks (10.16 cm length, 10 mm diameter), which emit more light, catch more individuals (38.2 *N. viridescens* captured per trap using thick glow sticks vs. 10.8 captured per trap using bracelet-size glow sticks). We suggest that glow sticks are activated in a darkened setting before placing them in traps as we found that 5–10 glow sticks per 100 were defective and did not produce light.

We first tested if glow sticks increased the number of captures per trap. Based on the distribution of the number of individuals captured per trap, we used a generalized linear model (PROC GENMOD in SAS; SAS Institute, Inc., Cary, North Carolina) to analyze the effect of glow sticks on the total number of newts and tadpoles captured per trap assuming the Poisson distribution. Of the 832 trappings (104 trap locations for eight sampling occasions), nineteen trappings were excluded from this analysis because of trap failure due to the trap not being closed correctly or variable water levels, which left a few traps without the funnel in the water. Next, we determined if male and female newts responded differently to the glow stick bait by testing for differences in trap sex ratio due to glow stick treatment using a one-way ANOVA. We calculated the proportion of males captured in each trap and performed an arcsine square-root transformation to achieve normality. A further 121 trappings were excluded from this analysis where no newts were captured (87 of the trapping occasions with zero captures were unbaited traps while 34 were baited with glow sticks). We weighted the ANOVA by number of individuals captured because traps which contained more individuals most accurately reflected the trapped sex ratio. Lastly, to account for spatial differences in capture success, we conducted paired t-tests to compare the mean number of newts and tadpoles captured at each trapping location with and without glow sticks (N = 4 trapping occasions per location with glow sticks and 4 trapping occasions per location without glow sticks). We square-root transformed the data to achieve normality. Of the 104 trap locations, only locations with all eight sampling occasions being successful were used in the analysis (N = 89 with 15 trap locations excluded due to one or more sampling occasions being failures).

Results.—Notophthalmus viridescens is the main salamander species present in Station Pond. Very small numbers of *Eurycea cirrigera* and *Desmognathus* spp. are washed in from a stream and a single adult *E. cirrigera* was captured, the only non-newt salamander captured during all sampling occasions. *Ambystoma jeffersonianum* is the only species of mole salamander known to be present at MLBS and is rarely seen in Station Pond (elevation 1160 m). A variety of frogs have bred in Station Pond (*Pseudacris*

TABLE 1. Total captures of *Notophthalmus viridescens* for each sampling occasion. Secondary sampling occasions within a primary period were separated by one day. The vast majority of captured tadpoles were native *R. catesbeiana*.

Date	Sampling Occasion	Primary Period	Male Captures	Female Captures	Total Newt Capture	Tadpole Captures
5 June 2006	1	1	466	83	549	75
7 June 2006	2	1	351	67	418	73
3 July 2006	3	2	367	125	492	149
5 July 2006	4	2	313	114	427	113
11 July 2006	5	3	137	60	197	97
13 July 2006	6	3	299	118	417	95
24 July 2006	7	4	352	124	476	104
26 July 2006	8	4	460	175	635	90

crucifer, Hyla versicolor, Rana clamitans, R. sylvatica, R. palustris), but Bullfrogs (*R. catesbeiana*) dominate the tadpole community and comprised the majority of tadpoles captured.

Over the eight sampling occasions, 3611 adult *N. viridescens* and 796 tadpoles were captured (Table 1). We found that glow sticks significantly increased the number of *N. viridescens* captured (Fig. 1; $\chi^2_1 = 163.75$, $P < 0.0001$). Glow sticks increased the number of individuals captured for both males (mean ± SE per trap = 4.77 ± 0.22 for glow stick trappings vs. 1.99 ± 0.11 for unbaited trappings) and females (mean ± SE per trap = 1.45 ± 0.09 for glow stick trappings vs. 0.63 ± 0.04 for unbaited trappings). Overall, more male newts were captured than female newts (Table 1; mean ± SE per trap = 3.36 ± 0.13 males and 1.03 ± 0.05 females). The male-biased sex ratio per trap was not significantly affected by glow stick use ($F_{1, 691} = 1.64$, $P = 0.20$).

Similar results were found for tadpole captures (Fig. 2). More tadpoles were captured in traps with glow sticks than in unbaited traps (mean ± SE per trap = 1.21 ± 0.09 for glow stick trappings vs. 0.78 ± 0.07 for unbaited trappings; $\chi^2_1 = 17.91$, $P < 0.0001$).

We also found that spatial variation in trap success was high. Trapping locations varied from capturing a mean of 0.25–16.5 *N. viridescens* individuals per trap when glow sticks were used and 0–7 mean individuals per trap when unbaited. When examining captures at each trap location we found that traps captured significantly more newts when baited with glow sticks compared to when unbaited (mean increase ± SE = 3.80 ± 0.35 individuals; Student's $t = 12.44$, d.f. = 88, $P < 0.0001$). Trap locations also captured significantly more tadpoles when baited with glow sticks (mean increase = 0.30 ± 0.12 individuals; Student's $t = 3.59$, d.f. = 88, $P = 0.0005$). Overall, glow sticks increased newt captures at trapping locations by an average of 273% and increased tadpole captures at trapping locations by an average of 93%

We observed no negative effects of funnel trapping or glow stick use on captured amphibians. Of the 3611 *N. viridescens* captured, only two individuals were found dead. Both were gaunt and found in traps with other healthy individuals. No tadpole mortality was observed.

Discussion.—We found glow sticks to be extremely effective at increasing capture efficiency of aquatic amphibians in funnel traps. Overall, when using glow sticks as bait, we captured greater numbers of adult *N. viridescens* and *R. catesbeiana* tadpoles than when no bait was used. When the spatial variation in capture success was removed we found that a given trapping location was more successful when glow sticks were used compared to when the trap was set unbaited.

We captured significantly more male newts than female newts. A male-biased sex ratio in pond populations has been reported in numerous studies of *N. viridescens* (e.g., Attum et al. 2002; Chadwick 1944; Massey 1990), but has not been found in juveniles entering ponds and lakes to breed (Gill 1978; Healy 1974; Hurlbert 1969). A biased sex ratio in individuals captured in ponds could be due to an actual biased sex ratio (possibly caused by differential survival between the sexes) or differences in

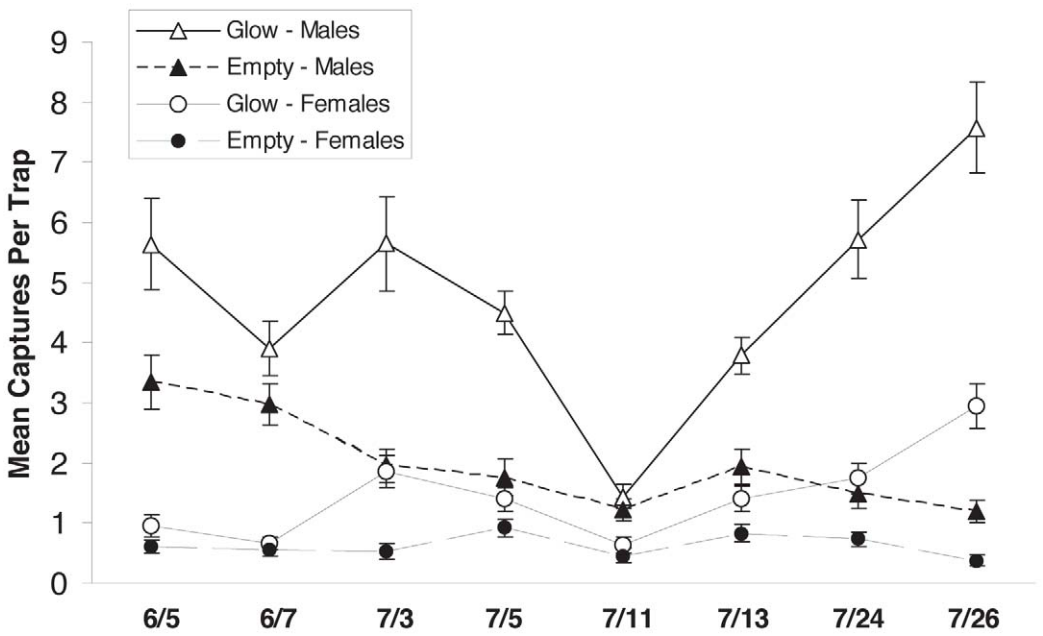

FIG. 1. Mean number of captures per funnel trap of *Notophthalmus viridescens* males and females over eight sampling occasions.

catchability between the sexes. For example, *N. viridescens* could have differences in movement patterns or microhabitat use between the sexes, which may result in female newts being more difficult to detect. Our data do indicate that male and female newts do not respond differently to glow sticks. Thus, while glow sticks increase captures for both sexes, one sex is not preferentially attracted to the glow stick bait compared to the other sex.

Capture efficiency varied over time likely due to differences in environmental conditions between sampling occasions. In particular, during the fifth trapping occasion (11 July 2006) less than half the typical numbers of individuals were captured. We noticed that a full moon and cloudless conditions resulted in particularly bright light conditions that evening. Moonlight can significantly impact the activity of aquatic salamanders (Anderson and Graham 1967; Green 2006) and we believe lunar illumination can lessen the effectiveness of the glow sticks compared to darker nights.

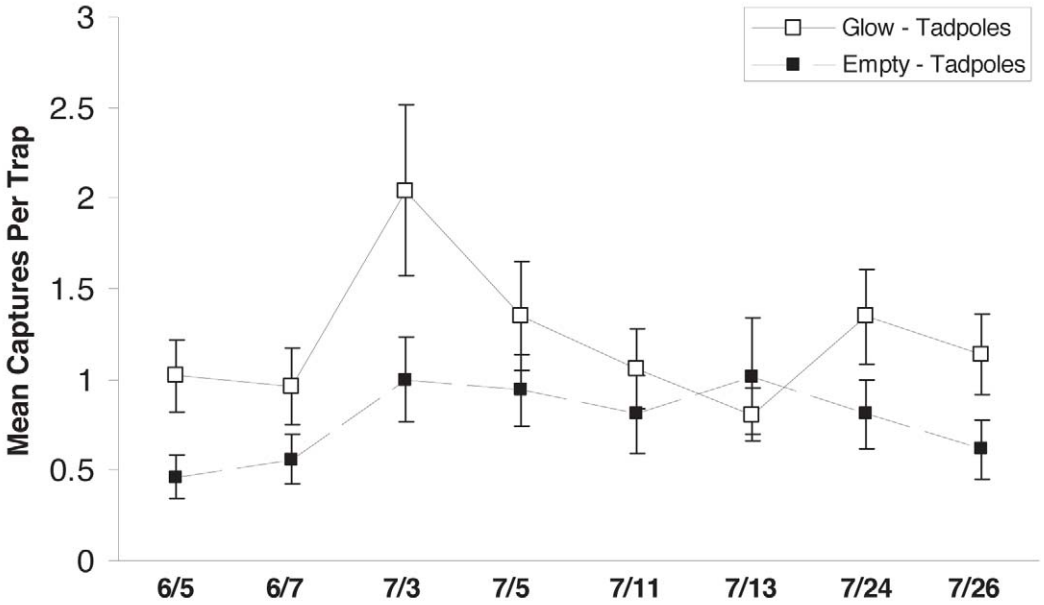

FIG. 2. Mean number of tadpole captures per funnel trap over eight sampling occasions. The vast majority of individuals captured were *Rana catesbeiana* due to their large size and numerical dominance in Station Pond.

The greatest number of individuals captured in a single trap was 37 *N. viridescens* and 14 *R. catesbeiana* for a glow stick trap and 14 *N. viridescens* and 12 *R. catesbeiana* for an unbaited trap. The pond trapped in this study is dominated by these two species but we suspect glow sticks would be effective for other species as well. Unless capturing too many individuals in a given night is a concern, we suggest the thickest glow sticks that produce the most light will result in the greatest number of captures per trap. However, further examination is necessary for studies of multiple species communities. As different species may vary in their catchability, response to glow sticks may also vary by species. We believe that glow sticks are a useful and inexpensive method for increasing capture efficiency in studies using funnel traps.

Acknowledgments.—Many thanks to Jessica Long and Jen Addo for field assistance. Permission to conduct this study and facilities were provided by Mountain Lake Biological Station. We are grateful to Henry Wilbur for advice, support, and the loan of minnow traps. Tami Ransom and Henry Wilbur provided comments that improved the manuscript. This research was conducted under UVA Animal Care and Use Committee Protocol 3063. Funding was provided by an NSF Graduate Research Fellowship to KLG and the MLBS REU-Sites program supported by NSF DBI-0453380.

Husbandry and Captive Reproduction in *Vipera nikolskii* (Viperidae)

DAVID JANDZIK
Department of Zoology, Faculty of Natural Sciences
Comenius University, Mlynská dolina B-1
SK-84215 Bratislava, Slovakia
e-mail: jandzik@fns.uniba.sk

Nikolsky's Adder (*Vipera nikolskii*) is a moderately short, thick-bodied viperid occuring in woodland meadows, forest-steppe, forest edges, and broadleaved forests in the Ukraine, Moldova, and southern to central Russia (Ananjeva et al. 1998; Bozhansky and Orlova 1997; Milto and Zinenko 2005; Sytnik and Loparev 2003; Vedmederja et al. 1986). An inhabitant of predominately wet areas with dense vegetative cover (Mallow et al. 2003), observations suggest that it readily takes to water (Stettler 1991, 1993; Gumprecht 1994; Trutnau 1998), as well as occasionally burrows within loose soil (Stettler 1993). Despite recent studies (Milto and Zinenko, 2003; Sytnik and Loparev, 2003; Tabachishin et al. 2003), the taxonomy of *V. nikolskii* remains unclear. It appears to be genetically similar to *V. berus berus* (Joger et al. 1997), however, morphologically distinct from other forms (Franzen and Heckes 2000; Milto and Zinenko 2005). Hence, it has been recognized as a full species (Vedmederja et al. 1986), a subspecies of *V. berus* (Joger et al. 1997; Milto and Zinenko 2005; Sokolov 2003), and tentatively, even a subspecies of *V. barani* (Stettler 1993; Nilson and Andrén 1997). Joger et al. (2003) additionally suggest that two clades exist within this taxon, one being closely allied to *V. b. berus* and *V. b. sachalinensis*, the other being a geographically restricted population of *V. nikolskii*.

Although Nikolsky's Adder often is maintained in captivity, reproduction is not commonly reported (Gumprecht 1994; Trutnau 1998). Three pairs (3.3), ranging in size from 460 to 605 mm TL, were collected from the Ukraine and acquired in 1999 and 2000. Upon arrival, the snakes were treated with a 0.0025% solution of Neostomosan spray (theta-cypermethrin; produced by Agrochemie®) to eliminate possible external arthropod parasites. Entizol (metronidazol; S-D Chemical®) against protozoans and Drontal Plus (praziquantel; Bayer®) against helminths were applied per os. All specimens were quarantined in pairs on a substrate of newspaper with the addition of a water bowl and plastic hide box. Both light and heat were provided by a 25-watt incandescent bulb positioned inside each enclosure for 13 h a day. Temperatures fluctuated between 22–28°C during the day, with the provision of a basking area that reached 35°C, dropping to 18–22°C at night. One pair of snakes succumbed from sepsis soon after being received. The remaining specimens were initially force fed pink mice, eventually accepting subadult laboratory mice every 7–10 days. After a three-year period, the snakes reached 640–715 mm in TL, with females being larger than males.

In November 2000, after an initial year-long acclimation period, both lighting and heating were discontinued. Temperatures were maintained between 18 and 22°C for two weeks before transferring specimens to individual plastic enclosures that were placed within a darkened room at temperatures of 7–9°C. Water was provided *ad libitum*. In February 2001, after a 90-day hibernation period, temperatures and lighting were gradually returned to a warmer regimen and all snakes commenced feeding within 20 days. Introductions were made after a 30-day period, though no reproductive activity was observed.

The specimens were cooled down again in mid-October 2001. Both females were allowed to hibernate three weeks longer than the males, however, all other conditions remained the same as the previous year. Upon introduction in March 2002, copulatory activity was observed twice between one pair lasting approximately 60 minutes during each episode. On 25 July 2002, 143 days after the second copulation, the female produced 5 infertile ova.

The hibernation conditions were changed the following year. The males were cooled down from the beginning of November to the end of February; the females were allowed to hibernate two weeks longer. Temperatures during this period were reduced to -1 to +2°C. After the hibernation period, individual snakes were exposed to sunlight for 2–4 h a day several times a week. Introductions were made in the beginning of April 2003 by placing one female at a time with both males. Ritualized combat behavior was subsequently noted between the males. Upon removal of one male, copulation was observed between the remaining pair. This regimen was repeated several times resulting in copulations lasting 60–90 minutes. The last copulation was observed on 12 April 2003, after which both females were housed together. The females were fed *ad libitum* and accepted prey until 13 June 2003. On 21 June 2003, 70 days after the last observed copulation (78 days after the first), the first female gave birth to seven neonates. Two of the neonates had kyphoscoliotic deformations in the anterior third of the body, one of which died shortly after rupturing the fetal membrane. The remaining young averaged 188 mm SVL (157–202 mm, SD = 17.1) and 5.8 g (5.1–6.2 g, SD = 0.4). On 2 July 2003, 82 days after the last observed copulation (89 days after the first), the second female gave birth to three neonates as well as 4 infertile ova. The young averaged 205 mm SVL (198–211 mm, SD = 6.6) and 8.3 g (7.2–9.1 g, SD = 0.9). All neonates shed immediately after escaping from the fetal membrane.

All juveniles were set up in small containers in groups of 2 to 3 on paper substrates with a water bowl. Temperatures were maintained between 22–25°C during the day and 20–22°C at night. Some juveniles accepted prey after being tease fed while others actually trailed and consumed envenomated prey. The remaining neonates were force fed sections of pink mice.

Previous authors reported that *V. nikolskii* is problematic when housed indoors under dry conditions (Gumprecht 1994; Trutnau 1998), yet my experiences suggest that this viperid may be successfully maintained and reproduced in a captive indoor environment after adequate quarantine measures. The gestation periods of 70 and 82 days are considerably shorter than the 130 to 133 days previously reported by Stettler (1993) and Grumprecht (1994). Although further studies are needed, the regimen of providing lower hibernation temperatures and exposing specimens to natural sunlight might have been important for successfully reproducing this species.

Acknowledgments.—I thank Frederika Kopincová and Regina Weisenpacherová for reviewing the manuscript and helpful comments on translation.

Prolonged Sperm Storage in the Asian Water Dragon (*Physignathus cocincinus*)

JOHN KAST
Department of Herpetology, Buffalo Zoo
300 Parkside Avenue, Buffalo, New York 14214, USA

Current address: Dept. of Herpetology, Fort Worth Zoo, 1989 Colonial Pkwy, Fort Worth, Texas 76110, USA; e-mail: jkast@fortworthzoo.org

Sperm storage has been documented in a number of species of squamates (Adams and Cooper 1988; Birkhead and Moller 1993; Conner and Crews 1980; Cuellar 1966). This note reports prolonged sperm storage in a captive female Asian Water Dragon (*Physignathus cocincinus*) at the Buffalo Zoo.

Three female and one male *P. cocincinus* were housed together in a large mixed species exhibit for a period extending from October to November 2004. Repeated copulations were observed during this period between the male and all three females. On different occasions all three females were observed depositing eggs on exhibit from December 2004 to March 2005. Due to medical reasons the male expired on 2 December 2004. On 3 July 2006, one female was observed digging test holes in the exhibit enclosure. Twelve eggs were discovered and collected the following day. The eggs, averaging 3 g, were placed in an incubator at 29°C. Over the next 30 days, eight eggs had collapsed and were found to be infertile after opening. After a period of 70 days, two of the four remaining eggs began sweating. The eggs stopped sweating after two days and began to cave in. Because there was no sign of pipping the decision was made to manually open the eggs. All eggs contained near full-term embryos, two of which were dead and beginning to decay. The remaining two were still living, but noticeably deformed. Major organs such as the heart and liver were outside the body cavity and attached to the yolk. Based on the date of the male's death and the date of egg laying, there was a minimum of 581 days between last possible copulation and deposition of the eggs.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 38, Number 1 (March 2007).

CAUDATA

AMBYSTOMA MABEEI (Mabee's Salamander). **DIET**. *Ambystoma mabeei* is a small mole salamander known from the Coastal Plain of southeastern Virginia to South Carolina. Relatively little natural history information is available for *A. mabeei* compared to its conspecifics. Recent studies have revealed the feeding ecology of *A. mabeei* larvae, however no published data exists for the diet of terrestrial forms (McCoy and Savitsky 2004. Southeast Nat. 3:409–416; Petranka 1998. Salamanders of the United States and Canada. Smithsonian Instit. Press, Washington, D.C. 587 pp.). On 7 Feb 2006 stomach contents of 35 freshly preserved juvenile to adult specimens (33.2–55.8 mm SVL) were examined. Twenty specimens contained prey, while 15 had empty stomachs (Table 1). Most prey items are invertebrates and are found terrestrially/fossorially, where *A. mabeei* spends a majority of its time. Plant parts were likely consumed incidental to prey capture. Supporting specimens (NCSM 18854) and stomach contents are in the NC State Museum of Natural Sciences collection.

TABLE 1. Stomach contents of freshly preserved *Ambystoma mabeei* adults (N = 20) collected near Laurinburg, Scotland Co., North Carolina. Data are presented as number of salamanders containing prey species (P).

STEPHAN**, Department of Entomology, North Carolina State University, Raleigh, North Carolina 27695, USA; and **JON M. DAVENPORT**, **DAVID A. BEAMER**, and **TRACY N. ROGERS**, Department of Biology, East Carolina University, Greenville, North Carolina 27858, USA.

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). **COTTONMOUTH ENVENOMATION**. *Amphiuma tridactylum* is sympatric with the Cottonmouth (*Agkistrodon piscivorus*) throughout the amphiuma's entire range. Both species reside in swampy lowlands and likely encounter one another frequently while searching for prey. Few reports are available on their interactions, but *A. piscivorus* is known to prey upon amphiumas (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press. Washington, D.C. 587 pp). On 8 July 2004 we captured a large (100 cm TL) *A. tridactylum* in a 1-m terrestrial funnel trap with a Cottonmouth (73 cm TL) in a small backwater slough (30.98ºN, 87.92ºW), in the Mobile-Tensaw Delta Wildlife Management Area Baldwin County, Alabama. When we approached the trap the amphiuma became agitated and began moving inside the trap. The Cottonmouth struck and envenomated the amphiuma several times on the head and mid-body. In our opinion, the snake expended the vast majority of its venom supplies into the amphiuma. The amphiuma then bit the snake with surprising force and shook the snake side-to-side. The amphiuma scraped dorsal scales off the snake and broke several of the snake's ribs. We separated the two individuals and within seconds the amphiuma's head swelled to twice its normal size and the bites on the body of the amphiuma each swelled to the size of a golf ball. We released the Cottonmouth and it slowly swam away, we do not know if the snake survived the altercation. We transported the amphiuma to a 151 l tank at the Univ. South Alabama Vertebrate Natural History Museum for observation.

The bites secreted copious amounts of mucus for several hours after the envenomation. The amphiuma's bites remained swollen for two days while it remained motionless on the bottom of the tank, except when it surfaced to breathe every 10–15 minutes. On the third day the swelling subsided and the amphiuma began swimming around the tank. We offered the amphiuma chicken liver, which it quickly consumed. We released the amphiuma on day five, after it made a full recovery. To our knowledge, this is the first record of an envenomation of an amphiuma by a snake. Besides the amphiuma, we are unaware of any amphibians that are able to recover from envenomation by a Cottonmouth. The exact mechanism that allowed the amphiuma to survive the envenomation is unknown and needs further study.

We thank the Alabama Department of Conservation and Natural Resources for funding this research.

CHIOGLOSSA LUSITANICA (Golden Striped Salamander). **PREDATION.** *Chioglossa lusitanica* is endemic to the Iberian Peninsula. It is one of the most endangered European amphibians and is listed as "Vulnerable" by the IUCN. This salamander has the ability to autotomize its tail when being preyed upon.

Few data exists on the predators of this species. On 2 July 2004 (1800 h; air temp 20.4ºC), a sub-adult *C. lusitanica* (SVL 42 mm) was observed in Zarzo (San Julian de Vigo, Paderne, A Coruña province, NW Spain; UTM 29T NH79) moving among moss cov-

ered rocks along a shady stream bank in a forest with *Alnus glutinosa, Corylus avellana, Salix atrocinerea* and *Fraxinus excelsior*. The salamander went under a rock and quickly came out pursued by a 17 mm land beetle, *Carabus* (*Eucarabus*) *deyrollei* (Carabidae). The beetle bit the salamander's tail, which immediately autotomized at the point where it was bitten, approximately a third of the way along its length. The salamander took refuge under another nearby rock. A few seconds later the beetle with the tail moving between its jaws, went back under the rock from where it originally emerged. Twenty minutes later, the rock was lifted and the beetle was observed eating the piece of detached tail, which was no longer moving. It is interesting to note the rapid recognition of the beetle as a predator on the part of the salamander, its quick escape, and the automatization of its tail upon the first encounter with the beetle's jaws.

On 8 July 2005, at the same site, about 250 m from the previous observation and 4 m from the river (1930 h; 23.0ºC air temp), I observed, upon lifting a rock, a dead juvenile *C. lusitanica* (SVL 26 mm), which was being devoured by another species of land beetle, a 30 mm *Carabus* (*Chrysocarabus*) *lateralis.*

These observations confirm the role of the large carnivorous carabid beetles as predators of juvenile *C. lusitanica*. These beetles are numerous and at least six species ranging in length from 15–35 mm are found in the area. These beetles share the same habitat (Atlantic riverbank forests) and microhabitats (under rocks and between layers of moss and dead leaves) as the salamander, likely resulting in them being important predators of *C. lusitanica*.

Submitted by **PEDRO GALÁN**, Departamento de Bioloxía Animal, Bioloxía Vexetal e Ecoloxía, Facultade de Ciencias, Universidade da Coruña, Campus da Zapateira, s/n 15071-A Coruña, Spain; e-mail: pgalan@udc.es.

CRYPTOBRANCHUS ALLEGANIENSIS (Hellbender). **CHYTRID FUNGUS.** The chytrid fungus, *Batrachochytrium dendrobatidis*, has been implicated as a cause of the amphibian decline worldwide (Berger et al. 1998. *In* Campbell [ed.], Declines and Disappearances of Australian Frogs, pp. 23–33; Green et al. 2002. Ann. New York Acad. Sci. 969:323–339; McDonald et al. 2005. Cons. Biol. 11:114–120). Ouellet et al. (2004. Cons. Biol. 19:1431–1440) provided a review of the historical distribution of chytrid in North America with a list of species that have been examined for the presence of *B. dendrobatidis*. To our knowledge, this is the first report of *B. dendrobatidis* in captive-reared and wild *Cryptobranchus alleganensis*. During the past four years the St. Louis Zoo has been caring for 126 juvenile Ozark Hellbenders (*C. a. bishopi*) and Eastern Hellbenders (*C. a. alleganensis*), collected as eggs by Unger (2003. MS Thesis, Southwest Missouri State Univ.) from the wild in Missouri, Georgia, and North Carolina. Unger (2003, *op. cit.*) collected eggs from Eastern Hellbenders in the Gasconade River, and from Ozark Hellbenders in the North Fork of the White River in Missouri. In March 2006, the captive-reared hellbenders were diagnosed with *B. dendrobatidis*. Further investigations led to the testing for chytrid on hellbenders from the wild in locations where eggs were collected in 2002 in Missouri. Eight skin scrape samples of *C. a. bishopi* from the North Fork of the White River were obtained on 22 May 2006 and one skin scrape sample from *C. a. alleganensis* was obtained from the Gasconade River on 1 June 2006. Polymerase chain reaction assay showed that two *C. a. bishopi* from the North Fork of the White River had *B. dendrobatidis*, while the one sample from the Gasconade River was negative for *B. dendrobatidis*. These data confirm the presence of *B. dendrobatidis* from hellbenders in captive-reared conditions and wild populations in the North Fork of the White River. *Batrachochytrium dendrobatidis* may be one reason for the decline of hellbenders in Missouri. Further testing for *B dendrobatidis* in Missouri and throughout the range of *C. alleganensis* is warranted to determine the extent and prevalence of this lethal fungus in wild hellbender populations.

We thank J. Wood from Pisces Molecular, Boulder, Colorado for analyzing the skin scrape samples, J. Longcore for graciously providing the laboratory standard culture for *B. dendrobatidis* to Pisces Molecular, and numerous individuals who assisted with field collections and logistic support. We also thank the Saint Louis Zoo veterinarian staff for providing collection materials and other technical support.

EURYCEA BISLINEATA (Northern Two-lined Salamander). **COLORATION.** The Northern Two-lined Salamander is described as having a pale yellowish to brown dorsum bordered by dark lines (Bishop 1941. The Salamanders of New York. New York State Mus. Bull. No. 324, Albany. 365 pp.; Conant and Collins 1998. A Field Guide to the Reptiles and Amphibians, Eastern and Central North America, Houghton Mifflin Company, Boston and New York, 616 pp.; Petranka 1998. Salamanders of the United States and Canada, Smithsonian Institution Press, Washington and London. 587 pp.). The 1373 records of this species from Québec in the provincial Atlas database (from D. Rodrigue, 22 Aug 2005) and the 293 records from Ontatio in the Ontario Herpetofaunal Summary (from M. Oldham, 21 Aug 2005); do not include any mention of unpatterned, dark, or pale individuals (Jock River specimens cited below are represented in the OHS by records that do not mention coloration). We report here two widely separated sites where we found unpatterned individuals of this species; we describe their pigmentation, and speculate on their significance. Specimens are deposited in the Canadian Museum of Nature (CMNAR).

On 1 Aug 1975, FWS, Aleta Karstad, and Paul W. Schueler visited the Jock River at the old Hwy. 16 bridge (Ontario: Ottawa-Carleton Region: Nepean, 45°15'35"N, 75°42'37"W, WGS 84), and collected a 69 mm pinkish, yellowish, cream-colored larval *E. bislineata*. Return visits to the seepage bank of this small clear rocky river, between *Tsuga canadensis* (Hemlock)/deciduous woods and grassy oldfields (now a municipal park) on 4, 9, and 10 Aug and 11 and 21 Sept 1975 resulted in the collection of more *Eurycea.* The largest individual (109 mm TL), had no dark pigmentation, but rather a pale mottled pattern all over the body. Since then, additional *Eurycea* have been found at this site, with one

unpatterned individual taken in 1980, and one possibly seen in 1995 (Schueler 2002. Trail and Landscape 36:68–71.

The overall frequency of unpatterned adults in the early sample was about 3%, and while none have been found recently, a sample of about 225 without an unpatterned individual would be needed to demonstrate a significant decline (p = 0.05) in the abundance of the unpatterned morph.

On 6 June 1999 J-FD and IP found two dark *Eurycea* at Rivière aux Rosiers, Ragueneau County, northeastern Québec (49°10'42"N; 68°36'35"W). This is a clear rock and gravel river, with fast current, 8 m wide, in Black Spruce (*Picea mariana*) forest, in an area of sport fishing and timbering, with a gravel access road. In 15 minutes, a search for salamanders under rocks on the river bank allowed them to observe 20 adults, all but two mentioned above being normally colored. One dark specimen (CMNAR 35817; 92 mm TL) was collected. The coloration of this live specimen was blackish with pale dots on the dorsum. The belly, usually yellow or yellowish at least in its posterior part (Bishop 1941, *op. cit.*; Petranka 1998, *op. cit.*), was gray.

On 21 July 2004 they returned to the site. An 8 min search yielded six typically-colored individuals (2 mature adults, 1 small adult, and 3 larvae). A second 25 min search yielded 21 individuals (15 adults and 6 larvae) with one adult and one larva dark in coloration. They then searched 200 m lower in the river (49°10'36"N; 68°36'34"W) for 10 min and found about 10 adults (1 dark morph). The river was 5–7 m wide at this site. Eleven specimens were collected, including those dark specimens (64 and 67 mm TL; CMNAR 35818). Overall, about 10% of those observed (5/57) were dark.

While specimens from these sites were described as 'black' and 'pale' upon capture (in life the Jock River specimen, CMNAR 21008, was "almost without non-melanic pigmentation except a faint pinkish blush all over the body"), the pattern of pigment in the specimens is similar. There is a background coverage of unclumped melanocytes which is interrupted by irregular pale areas, typically 1 mm in diameter, though 0.7 mm in CMNAR 19628 (which retained a trace of yellow in the pale patches in 1992, though no yellow was evident in 2006 or in the Rivière aux Rosiers specimens). The background melanocytes are sparsest in CMNAR 21008, denser in CMNAR 19628, and densest in the Rivière aux Rosiers specimens. The initially collected pale larva (CMNAR 16896) was "pinkish yellowish cream in color" at collection, while in 2006 it was creamy white with no trace of dark pigmentation or melanocytes.

The unpatterned adults differ from normal striped individuals both in completely lacking the densely melanic markings that constitute the lateral lines, and in the absence of irregular dark clumps of melanin which are scattered throughout, and sometimes concentrated along the dorsal midline of normal individuals (though the Rivière aux Rosiers specimens did have flecks of individual dark cells). Large normal larvae (60 mm) have the background coverage of unclumped melanocytes interrupted both by the pale patches seen in the unpatterned adults and the dark flecks seen in the striped adults. Smaller larva have the background coverage interrupted only by pale areas similar to those seen in the unpatterned adults (based mostly on CMNAR 21007 from the Jock River, FWS Jan 2006). The pale patches of the smaller larvae comprise the 6–9 pairs of dorsolateral pale spots described by Petranka (1998, *op. cit.*) and Bishop (1941, *op. cit.*).

The significance of this coloration is an open question. Unpatterned morphs have not been previously mentioned in this species, and there is no association with size, as large larvae from both sites were unpatterned. The simplest explication of this morph is retention of early larval coloration, with pale spots on the unpatterned adults that are about the same size (1 mm) as those on much smaller larvae. This is presumably the result of failure to develop the dark flecks that compose the lateral bands and other adult markings, and the persistence of the pale spots in the background coloration, but we cannot speculate further. The retention of larval pattern elements in these two populations, separated by about 700 km along the St Lawrence, Ottawa, and Rideau rivers, may be induced by some environmental characteristics, or genetic drift in isolated populations, without having a particular advantage for individuals.

We thank Aleta Karstad, the late Paul W. Schueler, Francis R. Cook, Mike Rankin, and numerous others for their valuable field assistance. Michèle Steigerwald's help at the Canadian Museum of Nature is appreciated, and Francis Cook has long encouraged our herpetochromic interests.

EURYCEA LONGICAUDA LONGICAUDA (Long-tailed Salamander). **PREDATION.** Natural predators of *Eurycea longicauda* are largely unknown. On 13 April 2006, 1500 h, we observed two adult *Thamnophis sirtalis sirtalis* that had recently fed on *E. longicauda*. The snakes were among six conspecifics observed within 10 m of a spring fed-pond lying adjacent to a small (< 10 hectare) fragment of upland deciduous forest. Upon capture one snake (ca. 55 cm TL) regurgitated an adult (45 mm SVL) male *E. longicauda*. The still living salamander was coated in shed skin and a mucus-like slime, possibly a combination of digestive enzymes and salamander skin secretion. The salamander was folded against itself, suggesting that it had been grasped and swallowed at mid-body by the snake. The tail was intact. Another *T. s. sirtalis* (size not recorded) was observed with the tail of an *E. longicauda* protruding from its mouth. The snake's mouth was held partially agape and was covered with a frothy secretion, presumably from the salamander. Eastern Garter Snakes are opportunistic foragers that are known to prey on other species of plethodontid salamanders including *E. bislineata, Desmognathus fuscus,* and *Pseudotriton montanus.* (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press. 587 pp.). This is the first report of predation on *E. longicauda* by *T. sirtalis* of which we are aware.

The spring-fed pond where this predation was observed is located in Wayne Co., Franklin Township, Ohio and is a productive site for *E. longicauda* (Wicknick et al 2005. Ohio J. Sci. 105:2–7). The hillside from which the spring emerges may serve as an underground winter retreat where these salamanders emerge in April

and return to in September and October (Bishop 1941. Salamanders of New York. New York State Mus. Bull. 324:1–365; Petranka 1998, *op. cit.*) A previous observation of predation on *E. longicauda* by *P. ruber* at this same locality (Reblin and Anthony 2001. Herpetol. Rev. 32:245–246) suggests that predators of *E. longicauda* might locate and exploit emergence sites when foraging.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). **REPRODUCTION.** Little is known about the disjunct Gulf Coast populations of *Hemidactylium scutatum*, with few records of adults reported from four counties (Gadsden, Leon, Walton, and Washington) in the Florida panhandle. Here we report the first published nesting and larval records of the species in Florida. Surveys for *H. scutatum* were conducted from 7–8 March 2005 in Joe Budd and Talquin wildlife management areas in Gadsden and Leon counties, Florida.

In Joe Budd WMA, Gadsden County, Florida, on 7 March 2005, three unattended, full-term *Hemidactylium* eggs were discovered in a tussock of mixed grass and *Sphagnum* sp. overhanging a small (ca. 1 m × 4 m) oxbow pool. The eggs hatched upon disturbance of the nest, and the larvae escaped to water before photographs could be taken. Alongside a slow-moving stream ca. 1.5 m wide, 5.5 m from the first nest, a female *H. scutatum* was observed tending 22 eggs under bark fragments in mixed pine needle/hardwood leaf litter adjacent to a sparse growth of *Sphagnum* sp. The eggs were located 17 cm above the waterline and contained fully developed embryos. Although *Sphagnum* sp. was present near both nests, the eggs were not located within dense hummocks of the moss, as is typified by the nesting microhabitat reported for more northern *Hemidactylium* populations (Breitenbach 1982. J. Herpetol. 16:341–346). When the second nest location was revisited on 8 March 2005, following heavy overnight rains, neither eggs nor the attending female could be found. The moisture from the rain may have triggered hatching and washed the larvae into the stream below. A single larval *H. scutatum* was dipped from the oxbow pool at the site of the first nest on 8 March 2005. Habitat at the Gadsden County site consisted of a meandering stream, 1–2 m wide with barely perceptible flow, surrounded by numerous oxbows in upland hardwood forest.

On 8 March 2005, a bottomland forest site in Talquin WMA, Leon County, Florida, was surveyed where adult *Hemidactylium* had previously been reported (Enge 1988. Proc. Annu. Conf. Southeast Assoc. Fish and Wildl. Agencies 52:336–348). Multiple *H. scutatum* larvae were seen in a shallow, seepage film wetland in the floodplain of a second-order stream in a steephead ravine. Two of these larvae were dipped by hand, photographed, and collected. Mosses noted around wetlands included *Thuidium*, *Climacium*, and some *Sphagnum*.

Previous reports indicate a geographical progression of nesting dates for *H. scutatum*, with females in warmer southern and coastal populations nesting earlier in the season, followed by populations in cooler, inland locales (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 587 pp.). Our findings corroborate this trend, and by extrapolating with a relatively low estimated incubation time of 38 days (Blanchard 1923. Am. Nat. 57:262–268), and a very conservative within-population egg-laying period of two weeks (Wood 1955. Am. Midl. Nat. 53:381–389), an early nesting date of 15 Jan 2005 is calculated. This would be the earliest reported nesting date to our knowledge, as would be expected from one of the southernmost coastal populations of *Hemidactylium*.

Photographs of the female, eggs, habitat, and larvae were taken and submitted with collection data to the Florida Natural Areas Inventory. Tissue collected from the female (autotomized tail) and larvae were preserved in 95% ethanol for genetic analysis at Bowling Green State University (sample ID#s: FL-GA-01, FL-GA-02, FL-LE-01, FL-LE-02).

We thank Jeremy Ross and Maria Tumeo for field assistance and Paul Moler for review and comments.

PLETHODON DORSALIS (Northern Zigzag Salamander). **MAXIMUM SIZE**. Although Smith (1961. The Amphibians and Reptiles of Illinois. Bull. Illinois Nat. Hist. Survey 28:1–298) reported 114 mm TL for the largest *Plethodon dorsalis* collected in Illinois, Conant and Collins (1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 3rd ed., Expanded. Houghton Mifflin Co. Boston, Massachusetts, 616 pp.) reported maximum body size for this species as 111 mm TL. On 10 March 2006 we captured an adult female *P. dorsalis* beneath a decaying board at a field/forest edge in Cooper Hollow, Cannon County, Tennessee, USA that surpassed the previous record length. The specimen, deposited in the Middle Tennessee State University collection (MTSU 342C) had a TL of 120.1 mm and a SVL of 56.0 mm when relaxed prior to fixation. After preservation in 10% buffered formalin for 11 days TL was 118.6 mm and SVL was 55.2 mm.

TARICHA TOROSA (California Newt). **FUNGAL INFECTION**. *Batrachochytrium dendrobatidis* (Bd) a fungal pathogen of amphibians, was first described as a new species in 1999 (Longcore et al. 1999. Mycologia 91:219–227). Bd is a recently emerged chytridiomycete fungus that has been identified as a causative agent in selected amphibian declines around the world (Berger et al. 1998. Proc. Nat. Acad. Sci. USA 95:9031–9036; Daszak et al. 1999. Emerg. Infect. Diseases 5:735–748; Bosch et al. 2001. Biol. Conserv. 97:331–337). In California this pathogen has been reported in wild populations of eight anuran species, Santa Cruz Long-toed Salamander (*Ambystoma macrodactylum croceum*), and

California Tiger Salamander (*Ambystoma californiense*) (Speare and Berger 2000. http://www.jcu.edu.au/school/phtm/PHTM/frogs/chyglob.htm; Vredenburg and Summers 2001. Herpetol. Rev. 32:151–152; Padgett-Flohr and Longcore 2005. Herpetol. Rev. 36:50–51). It has also been reported in Sonoran Tiger Salamander (*A. tigrinum stebbinsi*) in Arizona (Davidson et al. 2003. Copeia 2003:601–607). Herein, we report the first documented case of *B. dendrobatidis* in California Newt (*Taricha torosa*).

Ten California Newt larvae from nine different ponds (N = 90) in Joseph D. Grant County Park, Santa Clara County, California (37º20'29"N, 121º42'17"W; 650 m elev.) were collected in 2003 following a newt die-off observed by park personnel. The samples were preserved in 70% alcohol. We removed small pieces of toe skin from each specimen and microscopically examined unstained tissue for *B. dendrobatidis* zoosporangia. Six specimens from two different ponds were positive for the pathogen, as indicated by the presence of non-hyphal spherical zoosporangia with one or more inoperculate discharge papillae (Longcore et al. 1999, *op. cit.*). These data demonstrate that the potentially harmful pathogen is present in wild populations of California Newt.

Permission to collect California Newt specimens was authorized by permits issued by the California Department of Fish and Game (801160-02) and the County of Santa Clara Parks and Recreation Department to GEP. We thank D. Clark, K. Coffer, M. Goble, M. Jennings, M. Khosla, D. Rocha, and J. Wilcox for assistance in the field.

ANURA

AGALYCHNIS CALLIDRYAS (Red-eyed Treefrog). **REPRODUCTION**. *Agalychnis callidryas* occurs from southern Mexico to western Colombia adjacent to Panama, in tropical forests (Frost 2004. Amphibian Species of the World: an Online Reference. Version 3.0, 22 Aug 2004). This species lays its eggs in "nests" with an average of 33 eggs on the underside of leaves above (average height 106 cm) relatively shallow water (Leary and Packer 1998. Herpetol. Nat. Hist. 6:55–59). Breeding behavior of *A. callidryas* was observed in a small, semi-permanent pond at the border of the forest, on Bocas del Toro Island (9°25'01"N, 82°19'30"W, WGS 84, ca. 9 m elev.), in western Panama. A pair was observed on 17 July 2002 from 2200 h until 0530 h of the following day (7.5 h observation). Observation began at 2200 h when the pair was seen to enter amplexus. The pair was ca. 1.5 m above the water in a large shrub. Carrying the male, the female moved among the vegetation, apparently searching for an oviposition site. Egg-laying began at 0125 h (after 3.25 h of movement). This first oviposition site was at 1.7 m height, and the egg mass was 5.2 cm length, 2.3 cm width, 1.5 cm deep with 62 eggs, on a leaf that was 12 × 7 cm. Following oviposition, the female descended the vegetation, while carrying the male, to the ground, where she laid against the humid soil to absorb water. This lasted for 32 minutes. Then, the female, still carrying the male, climbed the vegetation searching for the next oviposition site. The second oviposition began at 0330 h at a height of 2.6 m, with egg-mass dimensions of 6.7 × 2.8 × 1.3 cm, with 52 eggs, on a 10 × 6 cm leaf. The pair then moved to another leaf and began the third oviposition. At 2.4 m height, this nest was 2.9 × 2.4 × 1.7 cm, with 25 eggs on a 14 × 8 cm leaf, ending at 0505 h. At that time, the pair moved to a larger branch and began climbing. At 0515 h the pair separated and the female continued climbing into the higher vegetation until lost from sight while the male settled on a leaf ca. 2.5 m height. Thus, in ca. 4 h, this pair oviposited three times, laying a total of 139 eggs, with only one pause for rehydration. We suggest that this species lays eggs in several nests to reduce predation risk on any one nest, since nest survival until larvae fall into the water is low. Eggs predators observed at this same pond included a cat-eyed snake (*Leptodeira septentrionalis*) and unidentified wasps.

Submitted by **REGINALDO ASSÊNCIO MACHADO**, Center of Biology and Nature Science, Federal University of Acre, Campus Floresta, Cruzeiro do Sul, State of Acre, Brazil (e-mail: anurans@uol.com.br); and **JAMES JOSEPH ROPER**, Zoology Department, Federal University of Paraná, State of Paraná, Brazil and the Institute for Tropical Ecology and Conservation-ITEC, Bocas Del Toro, Panamá (e-mail: jjroper@gmail.com).

AGALYCHNIS SPURRELLI (Gliding Leaf Frog). **CLUTCH SIZE.** The genus *Agalychnis* is composed of six species with Neotropical distribution, arboreal behavior, and oviposition on substrate out of water (Faivovich et al. 2005. Bull. Amer. Mus. Nat. Hist. 294:1–240). There are several studies of the natural history and breeding behavior of *Agalychnis*, but many aspects are unknown or incomplete. The largest clutch size reported for *A. spurrelli* had 67 eggs (Duellman 2001. Hylid Frogs of Middle America. SSAR Contrib. Herpetol. 18:1–1180 pp.; Savage 2002. The Amphibians and Reptiles of Costa Rica. Univ. Chicago Press 934 pp.). There is a record of a clutch with 533 eggs (Scott and Starret 1974. Bull. South. California Acad. Sci. 73:86–94) although Duellman (2001, *op. cit.*) suggested that report could be a multiple clutch. Here, I report two ovipositions, both larger than the clutch size previously reported for *A. spurrelli*.

During Oct 2005, I observed two ovipositions of *A. spurrelli* around an artificial body of water located in El Danubio, Region de Anchicayá, Department of Valle del Cauca, western Colombia. The frogs were in the water 15–20 min before they moved up into the vegetation and started to oviposit on the surface of a leaf. One clutch was 322 eggs (female SVL 11.3 cm), the other was 159 eggs (female SVL 8.8 cm). The first oviposition lasted ca. 30 min, while the second lasted ca. 19 min.

The larger oviposition described here is the biggest clutch size reported for *A. spurrelli*. Vargas et al. (2000. Rev. Acad. Colomb. Ciencias 24[90]:85–99) mentioned large clutch sizes (> 200 eggs) for *A. spurrelli*. The clutch size of 533 eggs reported by Scott and Starret (1974, *op. cit.*) was not verified as a single clutch because oviposition was not observed by the authors. Small clutch sizes (67 eggs) reported by Duellman (2001, *op. cit.*) and Savage (2002, *op. cit.*) for *A. spurrelli* could be due to: 1) no direct observation of oviposition; females may move to a different site and split the clutches into three or more parts (Fig. 1); and/or 2) differences in female body size (often related to the number of eggs laid); female *A. spurrelli* are larger in South American populations than in

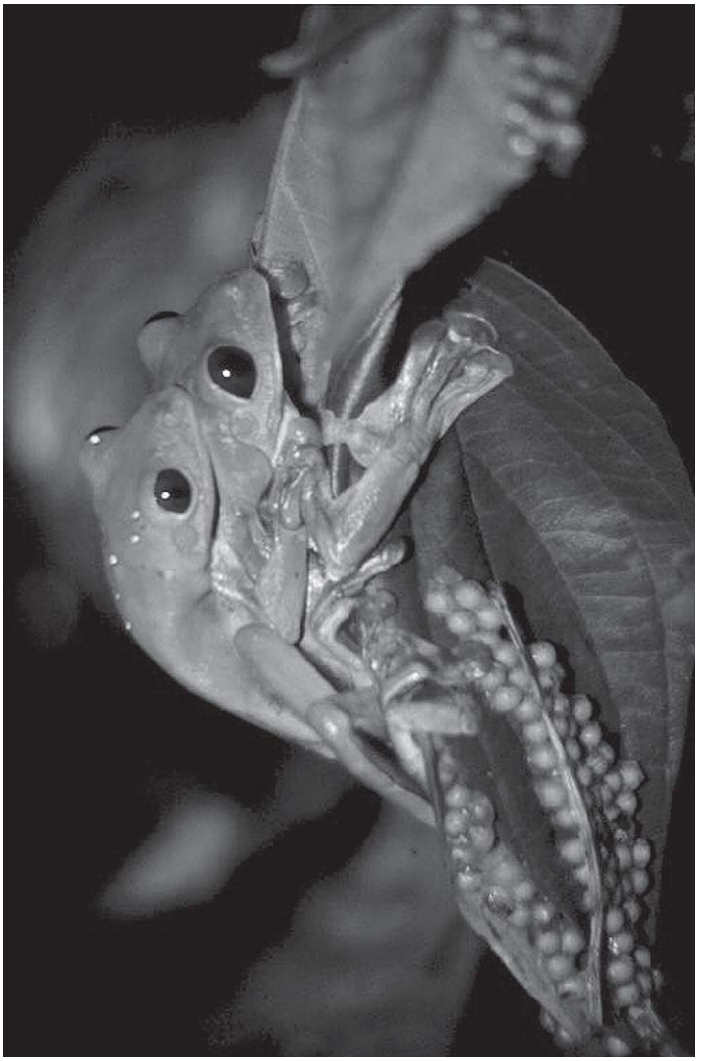

FIG. 1. Oviposition of the treefrog *Agalychnis spurrelli*. During oviposition the female may move to a nearby leaf, which divides the clutch into two or more parts (note several eggs in the upper right corner of photo).

Central American populations (Duellman 2001, *op. cit.*).

I thank J. D. Lynch for identification of these frogs.

Submitted by **FERNANDO VARGAS SALINAS**, Fundacion APUS, Carrera 11d No. 49-25, Santiago de Cali, Colombia; e-mail: vargassalinasf@yahoo.com.

BUFO AMERICANUS (American Toad). **PREDATION.** Although bufonid toads produce toxic compounds that render them unpalatable to many vertebrates, they have been reported as prey of several species of mammals, snakes, and other predators (Groves 1980. Amer. Midl. Nat. 103:202–203; Heinen 1993. Amer. Midl. Nat. 130:184–192, and references therein). On the evening of 22 June 2001, JAC collected a Brown Trout (*Salmo trutta*), 22.8 cm total length (TL), by angling in Beaver Creek along County Road 30, ca. 2 km upstream from its confluence with the Whitewater River, Winona Co, Minnesota, USA (T108N R10W S16). The belly of the trout was obviously distended, and it contained, in addition to a few insect larvae, 13 newly metamorphosed *Bufo americanus*. We returned to the same location on the evening of 24 June 2001 and collected 10 Brown Trout (22.5–25.4 cm TL) by angling. Two had empty stomachs, five contained invertebrate prey, and three (22.9–25.4 cm TL) contained, in addition to invertebrates, newly metamorphosed toads (minimum individual counts of 3, 15, and 48). The creek where the trout were captured is bordered by springfed marshes; newly metamorphosed toads were abundant along the roadside and at some sites along the stream margin. In some pools we observed toads floating downstream along the surface (as many as several dozen during a ten-minute period). Trout were feeding at the surface in the same pools, although they were also feeding on caterpillars, grasshoppers, and other insects of terrestrial origin. Newly metamorphosed toads measured 9–12 mm, and, as noted by Vogt (1981. Natural History of Amphibians and Reptiles of Wisconsin, Milwaukee Public Museum, Milwaukee, Wisconsin), have bright red warts. It is conceivable that the latter serve an aposematic function against some predators, but they would not have been visible to trout attacking from below.

Our observations suggest that predation by trout on toads is substantial at this locality, where Cochran and Cochran (2003. Herpetol. Review 34:360) reported predation by a trout on a Spring Peeper (*Pseudacris crucifer*). Brown Trout are not native to North America, but they are present in most of the 1145 km in 139 streams that currently are managed for trout in southeastern Minnesota (Thorn et al. 1997. N. Amer. J. Fish. Manag. 17:860–872). Thus, they may be an important source of mortality to anurans associated with streams in this part of the state.

BUFO BOREAS HALOPHILUS (California Toad). **LARVAL CANNIBALISM**. Cannibalism has been observed in anuran larvae within the genera *Rana* (Petranka and Thomas 1995. Anim. Behav. 50:731–739) and *Scaphiopus* (Low 1976. *In* Goodall [ed.], Evolution of Desert Biota, pp. 149–195. Univ. Texas Press, Austin.). Of the bufonids, cannibalism has been studied in the laboratory in *Bufo bufo* (Nagai et al. 1971. Agricult. Biol. Chem. 35:697–703) and *B. a. americanus* (Heinen and Abdella 2005. Am. Midl. Nat. 153:338–347) larvae, although field observations of larval cannibalism are lacking for these species. Recently, however, Jordan et al. (2004. West. N. Am. Nat. 64:403–405) documented *Bufo boreas boreas* larvae feeding on conspecifics and the larvae of two other species (*Rana cascadae* and *Pseudacris regilla*) in Oregon. Here we supplement the field observations of Jordan et al. (2004, *op. cit.*) with a report of apparent cannibalism by tadpoles of the California Toad (*B. boreas halphilus*) in California.

At 1330 h on 8 May 2006 while surveying the Santa Ynez Valley, Santa Barbara County, California for *B. californicus* larvae and egg masses, we observed eight *B. boreas halophilus* larvae in a circle feeding on a conspecific in Indian Creek (UTM Zone 11 0258628E, 3824554N; 1488 m elev.). The eight predators and the prey item were all similar in size (2–2.5 cm TL). These individuals were removed from the larger aggregation; the nearest individual was ca. 125 cm away. The event occurred ca. 20 cm from

the shore in shallow water (ca. 5 cm deep), which was 27.8°C. Although many *B. boreas halophilus* larvae were observed that day (estimated at > 100,000 individuals) and other trips to the area have been conducted, this was the only event of cannibalism observed.

Because the prey was dead at the time of the observation, it is impossible to state that the observed feeding was cannibalism rather than scavenging. Other factors suggest active cannibalism, however. Besides being partially eaten, the observed prey item appeared normal (with no anatomical abnormalities or signs of disease, and it was similar in size to the predators). Additionally, desiccation seems unlikely at the observation location and water depth, and no other dead conspecifics were observed in the area. Taken together, this observation most likely indicates a cannibalistic event, rather than one of scavenging. The small aggregation of eight individuals cannibalizing a conspecific is quite similar to events described by Jordan et al. (2004, *op. cit.*) in *B. boreas boreas* tadpoles, but this is the first account of apparent cannibalism in larvae of *B. boreas halophilus*.

We thank Richard Block, Nancy McToldridge, Alan Varsik, Sheri Horiszny, James Traverse, and Patrick Martin of the Santa Barbara Zoological Gardens (SBZG) for helping develop a partnership between SBZG and the USDA Forest Service on *Bufo californicus* and *Rana draytonii* conservation efforts.

BUFO BUFO (Common Toad). **FORAGING BEHAVIOR**. Two individual *Bufo bufo* recorded were observed climbing on Lamiaceae shrubs (genus *Rosmarinus*) in Falmouth (50°08'52''N, 05°04'45''W) Cornwall, United Kingdom. These individuals were observed actively foraging during the night (2217–2346 h) of 12 July 2006. Air temperature was 14°C. One individual was observed for more than 10 minutes moving on the top of the shrub; the other was observed while climbing. The common toad has largely been recognized as a terrestrial species, assembling in ponds and streams almost exclusively during the breeding season (Arnold 2002. Reptiles and Amphibians of Europe. Princeton Univ. Press, Princeton and Oxford. 288 pp.). This note provides the first record of *Bufo bufo* selecting shrubs as microhabitat to forage.

Submitted by **DANIEL PINCHEIRA-DONOSO**, Center for Ecology and Conservation, School of Biosciences, Univ. Exeter, Cornwall Campus, Penryn, TR10 9EZ, Cornwall, United Kingdom (e-mail: D.PincheiraDonoso@exeter.ac.uk)

BUFO BUFO (Common Toad). **DEPTH RECORD**. In temperate climates, several anuran species are known to spend the winter months hibernating underwater, often below a layer of ice (Emery et al. 1972. Copeia 1972:123–126; Matthews and Pope 1999. J. Herpetol. 33:615–624). Even during the activity season, some adult (Hutchison et al. 1976. Respirat. Physiol. 27:115–129) and larval

FIG. 1.*Bufo bufo* elevating its body off of the substrate in response to approach of submersible vehicle at 99 m depth in Loch Ness, Scotland, on 9 Sept 2005.

(Richmond et al. 1999. Herpetol. Rev. 30:90–91) frogs have been observed at depths of 3–8 m. Herein, we describe an observation of *Bufo bufo* at nearly 100 m depth in the Loch Ness of Scotland.

On 9 Sept 2005, at 1037 h local time, we were surveying the bottom of Urquhart Bay of Loch Ness, ca. 57°11'36"N, 4°35'36"W, ca. 250 m from the nearest shoreline. We were using a remote operating vehicle (ROV) with a mounted video camera. The surface air temperature was ca. 15°C, and the water temperature at the ROV depth (between 95–100 m) was 5.6°C. A toad was observed on the substrate, with its limbs splayed out slightly away from its body. The specimen was recorded on video for 78 sec, during which time it elevated its torso from the substrate (Fig. 1) and attempted to move away from the ROV. The toad's movements resembled lunges, but were very sluggish. The upper layers of sediment were disturbed with each of the toad's movements, indicating the loose substrate texture. Although the specimen was not collected, the species was inferred because it is the only bufonid known to occur in that part of Scotland (Gasc et al. 1997. Atlas of Amphibians and Reptiles in Europe. SEH and MNHN, Paris. 494 pp.).

The oligotrophic nature of the Loch Ness keeps oxygen saturation levels at around 80% and surface ice rarely forms during the winter months (Shine and Martin 1988. Scottish Nat. 100:111–199). In addition to a low metabolic rate inherent to the constant 5.6°C, the toad experienced pressures approaching 10 atm at 99 m. As such, its lungs would be completely deflated and the animal is negatively buoyant. We did not observe any swaying behaviors that would facilitate cutaneous respiration as have been documented in other species of anurans underwater (Hutchison et al., *op. cit.*).

We thank Gordon Ultsch and Richard Wassersug for discussing aspects of amphibian physiology with us, and the EIU herpetology group for their review of an earlier draft of this manuscript.

Submitted by **ROBERT H. RINES**, Academy of Applied Science, 24 Warren Street, Concord, New Hampshire 03301, USA; **ROBERT CHRIST**, SeaTrepid LLC, P.O. BUFO FERNANDEZAE (Lesser Common Toad). **BODY TEMPERATURE**. *Bufo fernandezae* is a typical inhabitant of northeastern Argentina, and is also found in Paraguay and Uruguay. (Cei 1980. Amphibians of Argentina. Monitore Zool. Ital., N. S. Monografia 2, 609 pp.). The thermal ecology of this toad is unknown. To study the thermoregulatory strategy of this species we measured the relationships between cloacal temperature (CT), snout-vent length (SVL), air temperature (AT), and substrate temperature (ST) of individuals of this species in natural microhabitats.

The study area was a permanent pond in the floodplain of the Middle Paraná River in Santo Tomé city, Santa Fe Province, Argentina (31º39'15.7"S, 60º45'35.3"W). The shore was largely covered with grass and *Solanum glaucophyllum* while the shallow areas were covered with *Ludwigia peploides*. Eleven individuals (SVL 5.5 ± 2.08 cm; mean ± SD) were captured between 1900 and 2200 h on 23 Nov 2005 in different microhabitats, including grass, mud, and shallow water. For each specimen, CT, ST, and AT were measured where the individual was collected with a digital thermocouple thermometer (Barnant model 600-1040).

Mean CT was 22.2 ± 1.3°C (N = 11, range 18.8–23.7°C). There were significant differences between ST and AT measured in each site (Mann Whitney, U = 14, N = 11, $p < 0.002$). CT differed significantly from AT (Mann Whitney, U = 21, N = 11, $p < 0.009$) but did not differ from ST (Mann Whitney; U = 0.43, N = 11, $p > 0.25$). CT showed a positive lineal association with ST (Spearman, R = 0.69; $p < 0.01$), but not with AT (Spearman, R = 0.27; $p > 0.47$). No association between the TC and SVL was observed ($p > 0.07$).

These results show that *B. fernandezae* analyzed in this study were predominantly thermopassive, following a mechanism in which the individuals do not actively invest time and energy selecting microhábitats for thermoregulation (Labra y Vidal M. 2003. *In* Francisco Bozinovic [ed.], Fisiología Ecológica y Evolutiva, pp. 207–224. Ediciones Universidad Católica de Chile. Santiago, Chile). The body temperature of this species depends primarily on the substrate temperature.

BUFO GRANULOSUS (Granular Toad). **PREDATION**. On 9 May 2005 at 1905 h we found a juvenile *Bufo granulosus* (SVL 36.1 mm) in the stomach of the colubrid snake *Leptodeira annulata* (SVL 417 mm; adult male) at buildings surrounded by grassy fields and a mosaic of Cerrado vegetation in the Brazilian Pantanal, Nhumirim Ranch (18º59'S, 56º40'W), Mato Grosso do Sul State, Brazil. After it regurgitated the frog (deposited in Coleção Zoológica de Referência do Campus de Corumbá - CEUCH 3671), the snake was measured and released. Bufonids are known for their skin toxins, although they do not seem to be an effective strategy against anuran specialists, like *L. annulata* (Duellman 1958. Bull. Amer. Mus. Nat. Hist. 114:7–152).

ÁVILA**, Programa de Pós-Graduação em Biologia Geral e Aplicada, Departamento de Parasitologia, Instituto de Biociências, UNESP, Distrito de Rubião Jr., s/n, CEP 18618-000, Botucatu, SP, Brazil (e-mail: robsonavila@gmail.com).

BUFO PUNCTATUS (Red-spotted Toad). **PREDATION**. Predation on chorusing *Gastrophryne olivacea* by *Thamnophis cyrtopsis* has recently been reported from Sonora, Mexico (Smith et al. 2005. Herpetol. Rev. 36:300). On 1 Aug 2005, we observed a similar event in the Pajarito Mountains of Santa Cruz Co., Arizona, USA. At ca. 0045 h, we encountered a mixed chorus of *G. olivacea* and *Bufo punctatus* calling from intermittent pools in a streambed adjacent to an unpaved road (31.460°N 111.249°W; 1243 m elev.). The sky was completely overcast with cloud cover and there was sporadic light rainfall. We observed four *T. cyrtopsis* foraging in and around the pools; two of the snakes had visible food boluses. We gently palpated these two snakes until they regurgitated; both contained recently swallowed *B. punctatus*. Smith et al. (2005, *op. cit.*) commented that in mixed breeding choruses of *Hyla wrightorum* and *G. olivacea*, *T. cyrtopsis* appeared to selectively consume the latter species. Our observation is noteworthy in that we observed *T. cyrtopsis* seemingly selecting *B. punctatus* in preference to more numerous *G. olivacea*. This provides an additional observation suggesting that foraging *T. cyrtopsis* may selectively consume specific anuran species in a chorus. This observation also further documents the potential importance of anurans as a seasonally concentrated and locally abundant food source for *T. cyrtopsis* in the Sonoran Desert region. A color transparency of a *T. cyrtopsis* with its associated food item is deposited at the University of Texas at Arlington slide collection (UTA 33309).

CHAUNUS ARENARUM (Dunes Toad). **DIET**. *Chaunus arenarum* is a common toad in coastal dunes of Brazil, Uruguay, and Argentina. During the night, individuals of this species may go to the beach to forage. On 11 Jan 2002 at 2200 h, we observed an individual feeding on a juvenile Plata Pompano (*Trachinotus marginatus*, Pisces; Carangidae) within the wave wash zone. To our knowledge, this is the first record of anurans feeding on a marine fish.

Submitted by **DANIEL LOEBMANN**, Programa de Pós-Graduação em Ciências Biológicas (Zoologia) do Instituto de Biociências, Campus da UNESP, Rio Claro-SP, Av. 24 A, 1515, Bairro Bela Vista, Rio Claro, SP, Brazil, CEP 13.506-900 (e-mail: pinguimfiel@yahoo.com.br); and **JOÃO PAES VIEIRA**, Fundação Universidade Federal do Rio Grande, Departamento de Oceanografia, Laboratório de Ictiologia, Avenida Itália Km 8, C.P. 474, Rio Grande, RS, Brazil, CEP 96.201-900 (e-mail: vieira@mikrus.com.br).

CHAUNUS BERGI (NCN). **ENDOPARASITES.** *Chaunus bergi* is associated with the floodplains of the Parana and Paraguay rivers in the northern Corrientes, eastern Chaco, Formosa, and northern and eastern Santa Fe, Argentina, and southern Paraguay (Céspedez 1999. Facena 15:69–82). The endoparasites of this toad have not been reported. The purpose of this note is to report the presence of three nematode species from Corrientes, Argentina.

Twenty adult (7 females, 13 males) *C. bergi* (mean SVL 30.78 mm ± 12.38 SD, range 2.81–43.0 mm; mass 4.67 g ± 2.32 SD, range 0.06–8.23 g) were collected in Corrientes, Argentina (27°28'S, 58°50'W) during Sept 2002–Nov 2003 and deposited in the herpetology collection of the Centro de Ecologia Aplicada del Litoral (CECOAL 2893, 2896–98, 3061–64, 3103, 3170, 3191, 3360–62, 3365–66, 3370–72, 3458). Toads were transported to the laboratory and placed in ether sulfuric solution. At necropsy, the alimentary canal, lungs, liver, and urinary bladder were examined for parasites by dissection. Nematodes were observed in vivo, counted and killed in distilled hot water, and fixed in 70% ethyl alcohol. They were cleared in glycerin or lactofenol and examined as temporary mounts.

Fifteen toads were parasitized (prevalence 75%) by three species of nematodes [in parentheses, prevalence (number infected frog/number examined × 100), mean intensity (mean number nematodes/infected frogs ± 1 standard deviation) and range]: one specimen of *Rhabdias* sp. localized in the lung (5%, 1), one hundred twenty-three *Cosmocerca podicipinus* localized in the large and small intestine and in the lung (65%, 9.46 ± 7.38, 1–24), and one hundred twenty-two *Cosmocerca parva* localized in the large and small intestine (40%, 15.25 ± 10.15, 2–30).

The nematodes are stored in the helminthological collection of Centro de Ecología Aplicada del Litoral: *Rhabdias* sp. (female 02103064), *C. parva* (male 02092898), and *C. podicipinus* (female 02092897).

In South America, nematodes belonging to the genera *Cosmocerca* and *Rhabdias* are widely distributed in amphibians and reptiles (Baker 1987. Mem. Univ. Newfoundland, Occas. Pap. Biol. 11, 325 pp.; Bursey et al. 2001. Comp. Parasitol. 68:21–35; Vicente et al. 1990. Rev. Brasil. Zool. 7:549–626) although they have not been found in *C. bergi*. This note represents the first record of *Rhabdias* sp., *C. podicipinus*, and *C. parva* in *C. bergi*.

HAMANN** (e-mail: monika_hamann@yahoo.com), Centro de Ecología Aplicada del Litoral (CECOAL), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET). C. C. 291. C. P. 3400. Corrientes, Argentina.

CHIASMOCLEIS PANAMENSIS (Panama Humming Frog). **PREDATION.** *Chiasmocleis panamensis* is a small, explosively breeding microhylid whose distribution is restricted to central Panama and northwestern Colombia (Nelson 1972. Copeia 1972:895; IUCN, Conservation International, and NatureServe 2004. http://www.globalamphibians.org/). Breeding choruses of *C. panamensis* are rarely observed and its ecology remains little known (Ibáñez et al. 1999. The Amphibians of Barro Colorado Nature Monument, Soberania National Park and Adjacent Areas Zone, Editorial Mizrachi and Pujol, S.A., Panama, 187 pp.). Here I report a predation event on *C. panamensis* by the colubrid snake, *Leptodeira annulata* observed on 18 May 2005 at 0320 h, under a partly cloudy sky and a moon roughly 4/7 full, following perhaps the heaviest rain of the newly begun wet season. The locality was Bridge Pond, Gamboa, Colón Province, Republic of Panama, 30 m elev. (9.116ºN, 79.700ºW).

While observing a chorus of *C. panamensis*, I noticed a *L. annulata* moving through the leaf-litter along the pond's edge. The snake had a bulge in the anterior portion of its body. I caught the snake and forced regurgitation of its prey. A still-living *C. panamensis* emerged from the snake, but the frog died within a few minutes. The frog was male, judging from the darkly colored throat region (Nelson 1972, *op. cit.*; Ibáñez et al. 1999, *op. cit.*), (SVL 25.45 mm). This is exceptionally large for a male *C. panamensis* (Nelson 1972, *op. cit.*). The snake measured 32.0 cm SVL, and 44.5 cm total length. *Leptodeira annulata* from Costa Rica, Brazil, and Ecuador are known to commonly prey on frogs (Vitt 1996. Herpetol. Nat. Hist. 4:69; Savage 2002. Amphibians and Reptiles of Costa Rica. Univ. Chicago Press, Chicago, 934 pp.).

Identification of the frog and snake were confirmed by César Jaramillo. The snake was released two days after capture. The frog (field number AJC 1164) was deposited in the Museo de Vertebrados de la Universidad de Panamá (MVUP number not yet available).

Submitted by **ANDREW J. CRAWFORD**, Smithsonian Tropical Research Institute, Apartado 2072, Balboa, Republic of Panama; e-mail: andrew@dna.ac.

CROSSODACTYLUS GAUDICHAUDII (Gaudichaud's Frog). **BEHAVIOR.** *Crossodactylus gaudichaudii* is endemic to southeast Brazil (states of Rio de Janeiro and São Paulo), inhabiting rocky streams inside forests (Heyer et al. 1990. Arq. Zool., São Paulo 31:291; Izecksohn and Carvalho-e-Silva 2001. Ed. UFRJ, Rio de Janeiro: 70). The only report on agonistic behavior comes from captive observations (Weygoldt and Carvalho-e-Silva 1992. Amphibia-Reptilia 13:35–45) and includes calling, visual displays, and agonistic interactions. Here we present the first record of agonistic behavior in this species in nature. On 10 Aug 2003, between 1210–1230 h, an agonistic encounter between two male *C. gaudichaudii* was observed in an area of Atlantic Forest at Ilha Grande, Rio de Janeiro state, Brazil. The observation was made along a trail in the forest, close to Vila Dois Rios Village (23º11'S, 44º12'W). One of the males was calling while perched on a rock ca. 15 cm above the water, at the margin of a puddle ca 1 m diameter and 3 cm deep. Four minutes after this male was located, a second male (distinguishable from the first one by its paler dor-

sum) entered the puddle and started to call from a distance of ca. 50 cm from the rock where the first male was perched, while facing the latter. After ca. 30 seconds, the two males apparently noticed each other's presence and began signaling with their four limbs. During the signaling, they raised the anterior part of the body and lifted the front limbs first and then the hind limbs, one at a time, apparently without a defined pattern. During those displays, the front limbs were completely raised from the substrate, but the hind limbs were not, with only the feet being lifted. Simultaneously, the male on the rock started to emit a differentiated call (presumably an aggressive encounter call). After ca. 2 min., the resident male jumped off the rock into the puddle below and approached the intruder male up to a distance of ca. 10 cm. The two males stayed face to face for about 1 minute, partially immersed and motionless. Then, the resident male jumped on the intruder and started a "wrestling" combat in which they wrapped their front limbs around each other and started rolling, venter to venter, until the resident male overturned the intruder and pushed him underwater with his forefeet, keeping him completely submerged. This combat sequence lasted for about five seconds, with the resident male seemingly subduing the invader. After the end of the combat, the resident male chased the invader off the puddle. Then, the resident male returned to the top of the rock it was initially sighted on, restarting calling activity. After about one minute, the invader male reappeared and returned to the center of the puddle. After about 30 seconds, the two males repeated the sequence of visual signaling and (in the case of the resident male) aggressive encounter calls. Then, the resident male jumped once again to the water and stayed at a distance of ca. 30 cm from the intruder, with the two males facing each other until another combat ensued. This time, however, it was the invading male who took the initiative to attack the resident. Again, the combat ended with the resident male chasing the invader off the puddle, before returning to his original perch on the rock to resume his calling activity. The invader male stayed outside the puddle for about 2 minutes and then returned, but, unlike the first time, he did not move to the center of the puddle and instead remained near its margin at a distance of about 1 m from the resident male's rock, almost totally submerged and silent. Apparently, neither of the two males suffered any kind of physical damage during the combats.

The observations made in the present study are similar to those described by Weygoldt and Carvalho-e-Silva (*op. cit.*) in captivity. The present observation indicates that males *C. gaudichaudii* may compete actively and directly for calling perches. The rock on which the resident male was perched apparently allowed a panoramic view of the puddle area, making it an important observation point at that particular site.

We thank Davor Vrcibradic for given helpful suggestions on the manuscript. The first author received a graduate fellowship from Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES). CNPq provided funding (processes # 307653/03 and 477981/03) to CFDR.

CTENOPHRYNE GEAYI (Brow Egg Frog). **BEHAVIOR.** Defensive behavior is common in many species of amphibians and can evolve stereotyped postures (Duellman and Trueb 1994. Biology of Amphibians. Johns Hopkins Univ. Press. 670 pp.). On 29 and 30 April 2004, two adult *Ctenophryne geayi* were captured in pitfall traps in the Reserva Florestal Adolpho Ducke (02°55'S, 59°59'W), Manaus County, central Amazonia, Brazil. While being manipulated for photographs, we observed three different defensive postures in *C. geayi*. During the daylight one individual (female, SVL 52 mm) assumed the following posture: crouched with the chin near the ground, eyes closed, limbs held tightly against the slightly arched body, and immobile. The other female (SVL 47.5 mm), manipulated during the night, exhibited a defensive posture of a fully inflated body with head down, forelimbs extended parallel to the body, and an elevation of the posterior part of the body, displaying a bright black color on the posterior and ventral surface of the thighs. The ventral surface of *C. geayi* is black with irregular white or cream spots. A third defensive posture (legs stretched backwards in a stiff-legged posture), described by Schlüter and Salas (1991. Stuttgarter Beitr. Naturk., Ser. A, 458:1–17), also was observed in the second individual. The first and third postures assumed by *C. geayi* could be associated with the cryptic coloration of the dorsum, thus protecting against visually oriented predators. The second posture, elevating the rear of the body by extending the hindlegs, causes these frogs to appear even larger which may help deter predators.

DENDROPSOPHUS COLUMBIANUS (NCN). **DISPERSAL**. In Europe there are sometimes rumors of live animals such as spiders or frogs that arrive as stowaways in shipments of fruit or flowers from South America. A package of flowers imported from Colombia to Vienna, Austria, included such a stowaway. On 15 May 2006, I was notified by the owner of a flower shop in Vienna that a recently received shipment of flowers of the genus *Heliconia* contained a live frog. The flowers were wrapped in newspapers from Colombia, and the shop owner reported that the shipment came from Cali, Colombia. The shop owner gave me the frog, which was in good condition. I maintained the frog for a week in captivity and shared photographs via the internet. The frog was identified as *Dendropsophus columbianus* (formerly *Hyla columbiana*) and donated a week later to a local frog breeder who had others of the same species. The geographic distribution of *D. columbianus* is limited to the upper Río Cauca valley and roughly centered on the city of Cali, Colombia (IUCN, Conservation International, and NatureServe. 2006. Global Amphibian Assessment. Downloaded 4 May 2006), although the frog has also been reported from northern Ecuador (Frost 2004. Amphibian Species of the World: an Online Reference. Ver. 3.0 [22 Aug 2004] http://research.amnh.org/herpetology/amphibia/index.html). According to my contacts, this case is not singular: a local frog breeder has

collected three *D. columbianus* in Vienna in the last few years. Species identification verified by Christian Proy.

ELEUTHERODACTYLUS BUCCINATOR (NCN). **CLUTCH SIZE AND PARENTAL CARE**. *Eleutherodactylus buccinator* is a moderate-sized leptodactylid known from the departments of Madre de Dios and Puno in southeastern Peru, in lowland tropical forest (Rodriguez 1994. Alytes 12:49–63). The species may also occur in Bolivia (Köhler 1999. Bonn. Zool. Monog. 48:69).

On 14 Sept 2004 we found a brooding adult female (SVL 41.0 mm; Fig. 1) *E. buccinator*. The female and eggs were found under leaf litter in the floodplain forest of the Rio Los Amigos Research Center (12°35'10"S, 70°05'26"W WGS 84; 270 m), Departamento Madre de Dios, Peru. The nest contained 43 eggs, each ca. 4 mm in diameter. The egg nest was in a ground depression approximately as large as the frog. We observed the female protecting the eggs and noted the development of eggs (with embryos moving inside the eggs) every day for a week after our initial finding. On 22 Sept we noted that both the female and the eggs had disappeared with no visible trace of predation around the nest. However, it is unlikely that all embryos had hatched at the same time, based on our observations of egg development in other species of *Eleutherodactylus*.

This is the first report of egg nest size and parental attendance in *E. buccinator*. Egg attendance in Eleutherodactlyinae frogs is performed by the male only (*E. coqui*, Townsend 1986. Behav. Ecol. Sociobiol. 19:187–195), the female only (*E. cundalli*, Diesel et al. 1995. Copeia 1995:354-360), or by both genders (*E. johnstonei*, Bourne 1998. Behav. Ecol. 9:1–7) depending on the species. Our finding excludes male-only egg attendance as the form of parental care in *E. buccinator*.

Honorio Delgado 430, Lima 31, Peru (e-mail: jdcarrillo@gmail.com); and **ALESSANDRO CATENAZZI**, Department of Biological Sciences, OE167, Florida International University, Miami Florida 33199, USA (e-mail: acaten01@fiu.edu).

FIG. 1. Female *Eleutherodactylus buccinator* attending terrestrial eggs.

ELEUTHERODACTYLUS COQUI (Puerto Rican Coqui). **ENDOPARASITES.***Eleutherodactylus coqui* is native to Puerto Rico and has colonized Culebra (Joglar and Rios-Lopez 1998. Herpetol. Rev. 10:101), Dominican Republic (Joglar and Rios-Lopez 1998. Herpetol. Rev. 29:107), Florida (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publ. Co., Malabar, Florida, 155 pp.), U.S. Virgin Islands (Thomas 1966. Quart. J. Fla. Acad. Sci. 28:375-391), Vieques (Joglar 1998. Los Coquîes de Puerto Rico: su Historia Natural y Conservación. Editorial de la Universidad de Puerto Rico, San Juan, 232 pp.), and the Hawaiian Islands (Kraus et al. 1999. Herpetol. Rev. 30:21-25). *Eleutherodactylus coqui* arrived in Hawaii in potted plants from the Caribbean or Florida in the late-1980s or early 1990s (Kraus et al. 1999. Herp. Rev. 30:21-25; Kraus and Campbell 2002. Biol. Inv. 4:327-332). There are currently no reports of helminths from Hawaiian *E. coqui*, but there are four reports from Puerto Rico: *Aplectana* sp., *Poekilostrongylus puertoricensis* (Schmidt and Whittaker 1975. Parasitology 70:287-294), *Oswaldocruzia lenteixeirai* (Moravec and Kaiser 1995. Carib. J. Sci. 31:252-268), and *Parapharyngodon garciae* (Dyer et al. 1995. Trans. Illinois State Academy Sci., 88:39-41). The purpose of this note is to report helminths from *E. coqui* from Hawaii.

Five hundred twenty *E. coqui* (mean SVL 26.1 mm ± 4.4 SD, range: 8-39) were collected between Dec 2000 and Sept 2005. Thirty-four were collected off Huina Road, 2 km W of Hwy 11, Puna District, (19°35'N, 155°05'W) Hawaii, Hawaii. The remainder were collected at Lava Tree State Monument, Puna District, (19°29'N, 154°54'W) Hawaii, Hawaii. Frogs were fixed in 10% formalin and preserved in 70% ethanol and are deposited at the Museum of Zoology, University of Michigan (UMZ), Ann Arbor, Michigan and the Bernice P. Bishop Museum, Herpetology Collection, (BPBM), Honolulu, Hawaii.

A mid-ventral incision was made in the abdominal wall and the digestive tract removed and examined for helminths. The body cavity was also examined for helminths. Nematodes were cleared in a drop of concentrated glycerol and identified. Trematodes were regressively stained in hematoxylin, mounted in Canada balsam and identified. One species of cosmoceroid nematode (n = 296, prevalence: number infected/number examined x 100 = 57 %; mean intensity; mean number helminths per infected frog = 5.0 ± 7.2; range: 1-66) was found in the intestine. Cysts containing larvae of the nematode *Physocephalus* sp. were found embedded in the stomach wall: prevalence: 1.0%, mean intensity: 15.0 ± 21.4: range 2-47. The trematode, *Mesocoelium monas*, was found in the intestine: prevalence: 0.4%; mean intensity: 1.0. Helminths were deposited in the United States National Parasite Collection, USNPC, Beltsville, Maryland and the Bishop Museum, BPBM, Honolulu, Hawaii as: *Cosmocerca* sp. (USNPC 97601, BPBM H142); *Physocephalus* sp. (USNPC 97602); *Mesocoelium monas* (USNPC 97600).

Cosmocercoid nematodes are identified to genus by the morphology of males, i.e., presence of plectanes, rosette papillae, or simple papillae. Our sample of cosmocercoids consisted on 294

females and 2 males; based on the presence of plectanes we have assigned them to *Cosmocerca*. Unfortunately, the post cloacal portion of the body was missing in both of the males, thus it was not possible to assign a species to our *Cosmocerca*. *Eleutherodactylus coqui* represents a new host record for each of the helminth species found in this study, *Cosmocerca* sp. *Physocephalus* sp. (larvae), and *M. monas*.

We thank E. Campbell, S. Joe, P. Krushelnycky, R. Sugiihara, W. Pitt, and P. van Dyke for collecting assistance and M. Saxby for kindly providing access to his property. D. Goto and J. Carlson assisted with dissections. This is contribution 2006-015 from the Hawaii Biological Survey at Bishop Museum.

ELEUTHERODACTYLUS DANAE (NCN). **REPRODUCTION**. In tropical frogs, reproductive variations in altitudinal gradients have not been documented. Studies of ectotherms found that females are larger and have bigger eggs in colder zones than in warmer zones. These variations are influenced by environmental characteristics, which are correlated with latitudinal variations. For this reason, it is not surprising to find the same responses to an increase in altitude, given its correspondence with environmental characteristics (Stevens 1992. Am. Nat. 140:893–911).

Here we report variations in body size, and number and size of eggs in *Eleutherodactylus danae*. This study took place in a mountain cloud forest (1240–2040 m) in Cosñipata Valley, Department of Cuzco, Peru. Between January and March 1999, we collected 5 reproductive females at each of the 3 study locations at different altitudes: Radiochayoc (13°02'S, 71°31'W, 1240 m elev.), San Pedro (13°03'S, 71°32'W, 1480 m elev.) and Suecia (13°02'S, 71°34'W, 2040 m elev.). Female SVL was measured to the nearest 0.01mm. In the laboratory we measured egg size and counted the number of eggs with a millimetric microscope. To measure the reproductive effort, body and egg mass and volume were measured using the Archimedes principle of water displacement. The difference between egg mass and female body volume represents female energy investment in the production of eggs.

We found that female body size and the size of eggs they lay are larger at higher altitudes (Table 1), showing an association between both variables (0.6634, $P < 0.01$). Furthermore, we found that the number of eggs produced decreases at higher altitudes (Table 1), observing that there is a negative correlation between the number of eggs and their diameter (-0.8916, $P < 0.001$). On the other hand, neither female body volume nor egg mass volume were different among the 3 locations. Although our observations suggest that the reproductive effort would decrease at higher altitudes. The increase in body size of females *E. danae* along its altitudinal range would be related to the decrease of temperature at higher altitudes (=5.5°C), while precipitation does not present any influence due to the amount of rain in the altitudinal range of the species, which is more than 400 cm (450 cm at 201 m elev. and 540 cm at 982 m elev., data taken at Cosñipata Valley, PROMANU project).

Studies have shown that frog species, living in high latitudes and cold zones when females are bigger, lay fewer and bigger eggs (Berven 1982. Evolution 36:962–983; Pettus and Angleton 1967. Evolution 21:500–507; this study). Studies among turtles, snakes, lizards, and frogs—including this study—found a correlation between female body size and egg size. If this is a phenotypic or genotypic trait it will have implications in the conservation of *Eleutherodactylus*, the genus that accounts for the majority of frog diversity.

ELEUTHERODACTYLUS RANOIDES (NCN). **DISTRIBUTION.** Many amphibian populations have been severely threatened by habitat destruction (Ron et al. 2003. J. Herpetol. 37:116–126). In addition, several populations are threatened by unknown agents even in unaltered habitats (Young et al. Cons. Biol. 15:1213–1223). Species that inhabit riparian habitats seem to be the most affected (Lips et al. 2003. Cons. Biol. 17:1078–1088). The *Eleutherodactylus "rugulosus"* species group is one of the best examples. There are eight species in this group in Costa Rica (Savage 2002. The Amphibians and Reptiles of Costa Rica. Univ. Chicago Press, Chicago. 934 pp.). In recent years, the only record of any of these was one population of *E. ranoides* inhabiting the Río Murciélago in Península de Santa Elena (Puschendorf et al. 2005. Herpetol. Rev. 36:53). This finding was based on previous observations of Sasa and Solórzano (1995. Herpetol. Nat. Hist. 3:113–126).

On 25 Jan 2005, we confirmed the continued presence of *E. ranoides* in the Río Murciélago. This was early in the dry season and the habitat was somewhat dry and the water level in the river

TABLE 1. Comparison of body size, egg size, and number of *Eleutherodactylus danae*, mean (± SE, range) at three study locations at different elevations using Kruskal–Wallis Test.

Variables	N	Radiochayoc (1240 m)	San Pedro (1480 m)	Suecia (2040 m)	H	P< 0.1
SVL (mm)	5	45.02 ± 2.32, 41.3–47.3	46.56 ± 1.41, 44.5–48.2	48.34 ± 1.39, 46.4–49.7	6.6506	0.036
Egg size (mm)	5	2.3 ± 0.41, 2.0–3.0	2.75 ± 0.31, 2.5–3.0	2.89 ± 0.23, 2.5–3.2	5.5317	0.0629
Egg number	5	35.4 ± 3.88, 32–40	32.6 ± 2.57, 30–35	31 ± 3.57, 28–34	4.8051	0.0905

was low. A total of 41 individuals were counted on rocks and under boulders in the stream (10º54'10"N, 85º44'48"W) between 1900–2100 h along a transect of 300 m. Water temperature was 28ºC. One specimen was collected.

On 26 Jan 2005, we visited two additional sites. The first one was the Río Potrero Grande. This is a river with many tributaries and a large volume of water during the rainy season. One frog was observed and collected (10º52'51"N, 85º43'07"W) between 1930–2030 h. In addition, we found 2 individuals between 1800–1915 h in the Quebrada La Danta (10º52'52"N, 85º43'04"W), a tributary of the Río Potrero Grande. It had a slow and continuous flow of water with a high water temperature (28ºC). One specimen was collected.

The same day we visited the Río La Calera, a slow flowing river. We found 11 individuals (10º52'54"N, 85º40'53"W) between 2245–2315 h. Water temperature was 28ºC. One specimen was collected. All specimens are deposited at the Museum of Zoology, Universidad de Costa Rica.

The sites where *E. ranoides* was found were always slow flowing, rocky, watercourses with high water temperatures during the dry season in dry forest. The existence of some unexplored watercourses in the Península de Santa Elena, which share the same characteristics, may represent new records for *E. ranoides* in Costa Rica.

We thank William Eberhard, Gustavo Gutierrez, Gilberth Barrantes, Gerardo Chaves, and Mark Budworth for comments on this manuscript.

ELEUTHERODACTYLUS STEJNEGERIANUS (Stejneger's Robber Frog). **PREDATION.** *Eleutherodactylus stejnegerianus* is a small, generally diurnal, leptodactylid frog common in the leaf litter of the humid lowlands and premontane Pacific slopes of western Panama and Costa Rica. In Costa Rica it occurs on the Meseta Central Occidental, in gallery forests in the subhumid northwest, and peripherally on the Atlantic lowlands near Laguna Arenal, 3–1330 m elev. (Frost 2005. Amphibian species of the world 3.0, http://research.amnh.org/herpetology/amphibia/index.php; Savage 2002. The Amphibians and Reptiles of Costa Rica: a Herpetofauna between Two Continents, Between Two Seas, Univ. Chicago Press, 954 pp; Scott 1976. Biotropica 8:41–58). Scott (1976, *op. cit.*) reported *E. stejnegerianus* (as *E. bransfordii*) as the most common amphibian species in the forest litter at study sites in the Osa Peninsula and San Vito, Puntarenas Province, Costa Rica.

Predation of *E. stejnegerianus* by the wandering spider, *Cupiennius coccineus* (Ctenidae), was observed on two separate occasions. On the evening of 8 Nov 2004 (~1830 h), within the La Merced National Wildlife Refuge, Puntarenas Province, Costa Rica (9°11'14"N, 83°45'43"W; ca. 60 m elev.) a *C. coccineus* (8 mm carapace length [CL]) was observed grasping a partially consumed *E. stejnegerianus* adult (~15 mm SUL). On the evening of 10 Nov 2004 (~1915 h), in the Oro Verde Biological Reserve, Puntarenas Province, Costa Rica (9°12'40"N, 83°1545'48"W; ca. 300 m elev.) another *C. coccineus* (8 mm CL) was observed grasping a partially consumed *E. stejnegerianus* adult (~15 mm SUL).

During both observations, the spider was grasping the frog with its chelicerae, positioning the frog under its body as it actively chewed on exposed frog viscera. Both frog/spider pairs were photographed, and submitted to the herpetological collection of the Los Angeles County Museum of Natural History (LACM-PC 1428-29).

To our knowledge these are the first reports of a ctenid spider preying on *E. stejnegerianus* in a natural setting. A variety of spider species are known to prey on anurans in tropical areas (Hayes 1983. Biotropica 15:74–76; McCormick and Polis 1982. Biol. Rev. 57:29–58). Based on the abundance of *E. stejnegerianus* (*sensu lato*, Scott 1976, *op. cit.*) and the variety and commonness of spider taxa in leaf litter, we agree with Hayes (1983, *op. cit.*) that spiders likely are important predators of tropical leaf litter anurans.

Thanks to F. G. Barth, Univ. Vienna, Austria for identification of the spiders; to C. Valenciano from the Asociación de Amigos de la Naturaleza del Pacífico Central y Sur for logistical support and assistance in the field, and to W. Odio and the Duarte Family of San Josecito for permission to collect from the La Merced National Wildlife Refuge and the Oro Verde Biological Reserve. We also thank T. Akre, J. Blackburn, and T. Robinson for photographs, and R. Sosa for suggestions that improved the manuscript. Scientific permits were issued by the Ministerio del Ambiente y Energia.

HELEIOPORUS AUSTRALIACUS (Giant Burrowing Frog). **PREDATION**. A series of predation events of adult *Heleioporus australiacus* were observed during a radio-telemetry study of a population in southeastern Australia. The study was undertaken between 1 Feb 2002 and 30 June 2004 (Penman et al. 2006. Wildlife Res. 33:35–40). During this time 33 individuals (19 male; 13 female; 1 sub-adult male) were radio-tracked for periods of 5–599 days, of which five males and one female were lost to predation. In four cases the predator was located and identified through the use of the telemetry signal. One male frog was eaten by a Laughing Kookaburra (*Dacelo novaeguinaea*). Three others (two males; one female) were eaten by a Red-bellied Black Snake (*Pseudichis porphyriacus*). The other two male frogs were also eaten by snakes that were observed briefly but were not positively identified. They were either *P. porphyriacus* or the Tiger Snake (*Notechis scutatus*). Four of the six frogs were taken by predators at their breeding sites after having migrated from their non-breeding activity areas. Furthermore, while another frog was last observed burrowed ca. 30 m from a breeding site, its recent movement and the presence of rain suggested that it was migrating to the breeding site and we

believe it was also predated at the breeding site. The final frog (taken by an unidentified snake) was predated 100 m from the breeding site and was consumed the night it was released. Hence this may not represent a "natural" predation event.

One of the *P. porphyriacus* was killed shortly after eating a telemetered frog and an examination found it had eaten two additional *H. australiacus* (one male: one female) that had been marked with PIT tags at a breeding site. We cannot be sure that the snake found these frogs at the breeding site, but it seems likely.

Rates of predation in the study were higher than expected. When distressed *H. australiacus* produces a sticky white substance from its back that was thought to be toxic to predators (Lemckert 2001. Nat. Aust. 26–33). However this substance is not a deterrent to all predators with one snake consuming three *H. australiacus* within a week.

We believe that all natural predation occurred immediately around the breeding sites, suggesting that these sites represent the highest mortality risk for this species. In this study, individuals spent less than 3% of the time in the breeding habitat with many individuals not accessing the breeding site every year (Penman 2005. PhD Thesis, Univ. Newcastle). It is possible that this represents a behavioral adaptation to the high predation risk. However, there is limited information on the breeding behavior or predation of *H. australiacus* in other areas to determine whether this is the typical situation.

Newcastle, Callaghan, New South Wales, 2308, Australia.

HYLA LOQUAX (Swamp Tree Frog). **PREDATION**. Wandering spiders (*Cupiennius;* Araneae, Ctenidae) are known to prey upon a variety of insects and small vertebrates (Toledo 2005. Herpetol. Rev. 36:395–400). Herein we report on invertebrate predation of an adult male *H. loquax* at the Cantarana Swamp, Organization of Tropical Field Studies La Selva Field Station. On the evening of 26 June 2002, between 2100–2200 h we observed a small chorus of male *H. loquax* calling from emergent vegetation and several amplectic pairs ca. 0.3–0.61 m above the water. We observed a wandering spider (*Cupiennius* sp.) perched on vegetation, digesting an adult male ca. 1 m above the water (Fig. 1). *Hyla loquax* has not been reported previously as a source of prey for spiders or any other invertebrate.

We thank Matjaz Kunter, Smithsonian Institute, Department of Entomology for spider identification, and J. Robertson, and S. Biswas for field assistance.

Submitted by **CRISTINA A. UGARTE** (e-mail: caugarte@ifas.ufl.edu), School of Natural Resources and the Environment, University of Florida, Everglades National Park 40001 St Rd 9336, Homestead, Florida 33034, USA; and **VENETIA BRIGGS**, Department of Biology, University of Miami, Coral Gables, Florida 33124, USA.

HYPSIBOAS FABER (Blacksmith Treefrog). **PREDATION.** Predators are a major source of mortality of tadpoles (Alford 1999. *In* McDiarmid and Altig [eds.], Tadpoles: The Biology of Anuran Larvae, pp. 240–278. Univ. Chicago Press, Chicago). The hylid frog *Hypsiboas faber* occurs from eastern to southern Brazil, southeastern Paraguay, and northern Argentina (Frost 2004. Amphibian Species of the World: an Online Reference. Ver. 3.0, 22 Aug 2004). The natural history of *H. faber* is fairly well known (Martins and Haddad 1988. Amphibia-Reptilia. 9:49–60; Martins 1993. Amphibia-Reptilia 14:441–421; Martins et al. 1993. Amphibia-Reptilia 14:307–309; Martins et al. 1998. Amphibia-Reptilia 19:65–73). Important predators include frogs, snakes, and water-bugs (Kluge 1981. Misc. Publ. Mus. Zool. Univ. Michigan 160:1–170; Martins et al. 1993, *op. cit*.).

During fieldwork in RPPN Estação Vera Cruz, Municipality of Porto Seguro, State of Bahia, Brazil (16º20'S, 39º10'W; 30–60 m elev.) I observed an adult turtle (*Acanthochelis radiolata*), capture and consume *H. faber* tadpoles. To my knowledge, this is the first report of predation on *H. faber* tadpoles by a turtle.

ITAPOTIHYLA LANGSDORFFII (NCN)**. DIURNAL BASKING.** Thermoregulatory behavior can be highly significant in the overall energetics of ectothermic animals (Lillywhite et al. 1973. Ecology 54:375–383) and yet constitute a challenge for amphibians in terms of cutaneous water loss (Tracy and Christian 2005. Physiol. Biochem. Zool. 78:839–846). On 27 February 2006 at ca. 1000 h, we observed a large tree frog, *Itapotihyla langsdorffii* (Anura: Hylidae), attached to a dry cliff face 30 m from the Cachoeira do Salto, Estação Ecológica Juréia-Itatins, municipality of Iguape, São Paulo State, Brazil (24°33'13"S, 47°13'48"W). The rock was facing the sun and warm to the touch; the frog's body (SVL 107 mm after preservation) was completely exposed to solar radiation, flattened with fore and hind limbs tucked along the lateral body surface, head lowered on its forefeet, and thus seemingly forming a seal between the underside of the frog and the rock surface (Fig. 1). Its eyes were shut. The basking site was ca. 10 m from the nearest vegetation (15 m from the nearest forest, *I. langsdorffii*'s natural habitat) and at least 20 m distant from wet rock surfaces. The individual was collected as part of a biological survey and when first seized it voided a substantial volume of clear liquid. Upon dissection, we found that the animal's stomach and upper intestine were empty; the lower intestine contained unidentified debris and a few fragments of arthropods.

Itapotihyla langsdorffii is endemic to the Brazilian Atlantic coastal rain forest (Izecksohn and Carvalho-e-Silva 2001. Anfíbios do Município do Rio de Janeiro. Editora UFRJ, Rio de Janeiro), and we were surprised to encounter this nocturnal mesophyllic species basking on a warm summer morning. Thermoregulatory behavior has been documented in hylids of arid habitats; *Hyla arenicolor*, a North American species, exhibits the same stereotyped posture to conserve water while basking (Snyder et al. 1993 J. Arid Environ. 25:321–329). The Brazilian hylid *Bokermannohyla*

FIG. 1. Basking site (indicated by arrow) for *Itapotihyla langsdorfii* near the Cachoeira do Salto, Estação Ecológica Juréia-Itatins, São Paulo State, Brazil.

alvarengai is commonly found in arid open rocky habitats ("campos rupestres;" Sazima and Bokermann 1977. Rev. Bras. Biol. 37:413–417), and its resting posture appears similar to that we observed in *Itapotihyla*. Also, *B. alvarengai* seems to modify the coloration of its skin in response to temperature and illumination (Tattersall et al. 2006 J. Exp. Biol. 209:1185–1196), an ability that remains to be investigated in *I. langsdorffii*. Tracy and Christian (2005, *op. cit.*) suggested that daytime retreat site selection by frogs might be important for temperature regulation and therefore influences daily energy budgets, allowing them to digest and/or grow more quickly. Basking by *I. langsdorffii* might be related to temperature regulation due to its large size; in addition, its dorsal color pattern closely resembles rock lichens despite its arboreal habit, suggesting that basking on rocks might be a common behavior for this species and the coloration may have adaptive value in predator avoidance under exposed conditions.

The voucher specimen (CFBH 11474) is housed in the Coleção de Anuros Célio F. B. Haddad, Depto. de Zoologia da Universidade Estadual Paulista, campus de Rio Claro.

LEIOPELMA PAKEKA (Maud Island Frog). **REPRODUCTION.** The leiopelmatid frogs of New Zealand are among the most archaic anuran species in the world. The genus is comprised of three extinct and four extant species, all currently threatened. Despite the attempts at conservation of these species, little is known about their reproductive biology. For two of the four extant species, *L. pakeka* and *L. hamiltoni*, which were recently recognized as separate cryptic species (Bell et al. 1998. J. Royal Soc. New Zealand 28:39–54), there are no published reports of mating in the wild nor have eggs been observed in the wild. All of the current information about reproduction in these species comes from captive individuals (Bell 1978. Herpetologica 34:340–354; Bell 2002. Unpubl. report to NZ Native Frog Recovery Group).

During recent field studies on Maud Island in the Pelorus Sound, New Zealand (41°01'S, 173°53'E WGS 84), three pairs of amplecting frogs were found up trees. The first pair was found in Dec 2005, and two additional pairs were found in Jan 2006. This behavior is surprising for these species, which are thought to be extremely saxicolous and spend the majority of their lives under rock piles. Though all frogs from amplecting pairs were examined, none appeared to be carrying eggs and no eggs were found

in the vicinity of the event. To our knowledge this type of arboreal mating behavior in *Leiopelma* has only been anecdotally reported twice before. In 1972, a NZ Wildlife Service worker took photographs of pairs of frogs in the trees on a rainy night (R. Morris, pers. comm.). In 2004, a pair of frogs in amplexus was captured up a tree in December (Waldman 2004. ARC Conference, Captivity, Reintroduction and Disease Control Technologies for Amphibians, Victoria, Australia, URL: http://frogs.org.au/arc/conference.html). This pair was taken to Canterbury University where the male later died. No eggs were laid.

These sightings provide information on the timing of reproductive events for *L. pakeka* and likely for the closely related *L. hamiltoni*. All events appear to occur later than those recorded in captivity in Wellington, New Zealand (Bell 2002, *op. cit*.). Despite these recent sightings, eggs of *L. pakeka* or *L. hamiltoni* have not been found laid in the wild and much remains unknown about their reproductive biology. Current work is investigating the timing, effects of habitat, behavior, and other aspects of *Leiopelma* reproduction.

We thank S. Madill and A. Frost for assistance in the field. We are grateful for funding from the SSAR Grants-in-Herpetology and the SRARNZ Herpetological Research Award. Department of Conservation permit granted under authority number NM-16664-RES.

LEPTODACTYLUS OCELLATUS (Rã Manteiga). **DIET**. *Leptodactylus ocellatus* has a broad distribution that includes Brazil, Argentina, Paraguay, and Uruguay (Maneyro et al. 2004. Iheringia 94[1]:57–61). Several reports describe the diet of this species (Gallardo 1964. Anfibios de los Alrededores de Buenos Aires. Buenos Aires, Editorial Universitaria de Buenos Aires; Basso 1990. Monografias Asociación Herpetológica Argentina 1:1–70; França et al. 2004. Stud. Neotrop. Fauna Environ. 39[3]:243–248), which consists of arthropods, mollusks, and amphibians. An adult male *L. ocellatus* (Museu de Ciências e Tecnologia of the Pontifícia Universidade Católica do Rio Grande do Sul [MCP 8865]; SVL 91.8 mm) was collected at 0730 h on 28 Jan 2006, under a rock on the seashore in the State of Santa Catarina (Municipality of Palhoça). The specimen was dissected and two partially digested *Ligia* sp. (beach woodlouse) were found in the stomach. Maneyro et al. (2004, *op. cit*.) cite isopods and amphipods in the diet of *L. ocellatus* from Uruguay. However Maneyro (pers. comm.) informed us that the isopods found in the diet of *L. ocellatus* in Uruguay are a terrestrial species popularly known as woodlouse. This is the first record of *Ligia* sp. in the diet of *L. ocellatus*.

MEGAELOSIA APUANA (NCN). **PREY**. *Megaelosia apuana* is a recently described giant torrent frog from Pedra Azul, municipality of Domingos Martins, State of Espírito Santo, Brazil (Pombal et al. 2003. J. Herpetol. 37:453–460). Congeners are known to prey on other anurans (Giaretta et al. 1993. J. Herpetol. 27:276–285), but this habit has not been reported for *M. apuana*.

Herein we report a predation attempt by *M. apuana* on *Proceratophrys boiei*. The observation was made on 25 Sept 2005 at 2000 h near the type locality for *M. apuana* in Pedra Azul (20°24'47"S, 41°01'30"W, 1100 m elev.). We observed an adult *M. apuana* (SVL 83 mm) attempting to swallow an adult *P. boiei* (SVL 52 mm). At the moment of the observation, both individuals were in a shallow pond near a stream at the forest edge. The *P. boiei* was being bitten on its cloacal region and had both hind limbs outside of the *M. apuana* mouth. We did not see if the prey was captured on land and brought to the water or if it was captured in the pond. As a defensive behavior the *P. boiei* inflated its body, not allowing the *M. apuana* to finish swallowing it (Napoli 2001. Herpetol. Rev. 32:36–37; Toledo and Zina 2004. Herpetol. Rev. 35:375). After nearly two minutes of observation the *P. boiei* escaped its predator, which stayed motionless for a few moments before it tried to escape.

Both specimens were captured and deposited in the Amphibian Collection Célio F. B. Haddad (CFBH), at Universidade Estadual Paulista, Rio Claro, São Paulo (CFBH 10811, *M. apuana*; CFBH 10812, *P. boiei*).

We thank João L. Gasparini and Charles R. Nunes for help with fieldwork. Célio F.B. Haddad read the manuscript and provided valuable suggestions. The Brazilian National Institute of Natural Environments (IBAMA) issued the collecting permit to J.L. Gasparini (license number 054/05 – IBAMA/RAN, Process number 02001.002792/98-03).

ODONTOPHRYNUS OCCIDENTALIS (NCN). **BODY TEMPERATURE**. *Odontophrynus occidentalis* inhabits western Argentina from Catamarca to Neuquén and Río Negro, eastward into the Pampa and Sierras de Cordoba (Cei 1980. Amphibians of Argentina. Italian J. Zool., N.S. Monografia 2, 609 pp.). The thermal ecology of this species has not been previously studied. Herein we briefly describe select aspects of the thermal ecology of *O. occidentalis.*

Our study area was located 70 km SE of San Juan City, Argentia on National Route N 141. This area is in the Monte phytogeographic Province (Cabrera 1994. Enciclopedia Argentina de Agricultura y Jardinería, Tomo II, Regiones fitogeograficas Argentinas, Editorial ACME S.A.C.I.). Elevation reaches 749 m. The region is arid with an annual mean temperature of 20°C (mean max 40°C, mean min 16°C). The rains occur mostly in the summer with an annual average of 84 mm.

Thirteen *O. occidentalis* (mean SVL 5.03 cm; SD 1.7 cm) were collected on 16 Dec 2005. The cloacal temperature (TC), soil temperature (TS), and air temperature (TA) were measured with a digital thermometer (Barnant Model 600-1040). TS and TA were

significantly different (t-student, t = -2.5, df = 24, p < 0.01). Mean TC was 20.5°C (SD = 1.6, range = 19.4–24°C, N = 13). TC was positively associated with TS (Spearman, R = 0.6; p < 0.02), and TA (Spearman, R = 0.67; p < 0.02). TC was not significantly different from TS (t-student; t = -0.3, df = 24, p > 0.7) and was significantly different than TA (t-student, t = 2.33, df = 24, p < 0.02). There was no association between TC and SVL (p > 0.91).

These results indicate *O. occidentalis* in this situation is thermopassive, a mechanism where individuals do not need to invest time and energy actively selecting microhabitat for thermoregulation (Labra and Videl. 2003. *In* F. Bozinovic [ed.], Fisiología Ecológica y Evolutiva, pp. 207–224. Ediciones Universidad Católica de Chile. Santiago, Chile). These individuals were in a breeding chorus, when the biggest demand for energy is in calling to attract females, thus this thermopasive mode seems to be the most effective strategy for thermoregulation.

We thank Alejandro Laspiur for help with fieldwork.

OSTEOCEPHALUS YASUNI (NCN) and ***OSTEOCEPHALUS PLANICEPS*** (NCN). **TERRESTRIAL BEHAVIOR**. Frogs of the genus *Osteocephalus* are largely arboreal and nocturnal and occur throughout the Amazon Basin and along the eastern Andean slope. There are 18 species recognized, at least 8 of which are known from Yasuní Research Station (YRS) (0°40'S, 76°24'W) and Tiputini Biodiversity Station (TBS) (0°37'S, 76°8'W) in the Province of Orellana, Ecuador. Information on the natural history of most *Osteocephalus* species is scarce, although species exhibit a variety of reproductive strategies including the use of streams, seasonally flooded pools, and phytotelms for amplexus and egg deposition.

Osteocephalus yasuni and *O. planiceps* are common species at YRS and TBS. Eggs and tadpoles are undescribed, but it is suspected that *O. planiceps* is a phytotelm breeder, because males often call from bromeliads in the canopy (Ron 2006. http://www.bio.utexas.edu/grad/ecuador/web/yasuni/esp/anfyas.htm), and that *O. yasuni* uses seasonally flooded ponds for breeding, because males form large choruses around pools after heavy rains (Ron and Pramuk 1999. Herpetologica 55:433–446). Like other *Osteocephalus* species, *O. yasuni*, and *O. planiceps* are nocturnal and arboreal (Ron 2006, *op. cit*.) although, *O. yasuni* choruses may occasionally continue calling into the day following their nocturnal assembly and pairs in amplexus have been witnessed during the morning hours (pers. obs.).

Here we report an unusual behavior: during 2 field seasons in the Ecuadorian Amazon, we observed *O. planiceps* and *O. yasuni* females sleeping in the litter during the day. The first individual, a small adult female *O. yasuni* (SVL 48.9 mm, mass 6.97 g), was found at YRS on 24 May 2005 (ca. 1030 h) in a 5 × 5 m forest floor quadrat that was sampled for leaf litter herpetofauna. The frog was buried under the leaf litter and completely concealed from view. Despite disturbance, it remained motionless until it was picked up by hand, at which point it attempted to escape. During our second field season, we encountered three additional *O. yasuni* and two *O. planiceps* sleeping in the litter at TBS. On 27 March 2006, we found an adult female *O. planiceps* (SVL 56.5 mm, 9.74 g) at ca. 1030 h. On 28 March at ca. 830 h, we encountered a second *O. planiceps* (SVL 59.5 mm, 12.05 g). We found two *O. yasuni* on 29 March: the first (SVL 57.0 mm, 12.14 g) at ca. 1030 h and the second (SVL 59.0 mm, 14.6 g) at ca. 1500 h. All were found during searches of 5 × 5 m forest floor plots, and they were buried under the litter, just as the first individual found at YRS in 2005. On 31 March at ca. 1000 h, while searching an 8 × 8 m quadrat we encountered a third female *O. yasuni* (SVL 59.2 mm, 11.28 g) sleeping on the ground. Five of the individuals were photographed and released.

All six females were found in primary, terra firme forest within a week following a heavy rain. At TBS, the rain stimulated a very large chorus of *O. yasuni* males. However, the females were found a kilometer or more away from where the males were calling and they were completely inactive when found. Because the females were so well buried under the litter, the possibility that they fell from the trees seems unlikely. The leaf litter habitat may represent an important and previously unrecognized part of the life cycle of adult female *O. planiceps* and *O. yasuni*. We suggest that this behavior may be typical and that *O. planiceps* and *O. yasuni* may only exhibit this behavior in the breeding season, though this warrants further investigation.

We thank our field assistants at YRS and TBS, especially A. Enomenga and I. Nenqemo, as well as K-H. Jungfer and D. Cisneros-Heredia for verifying species identification. These observations were made during dissertation fieldwork of JLD, which was supported by grants from the Conservation, Food and Health Foundation, and the Louisiana Governor's Office of Environmental Education. Research was conducted under permit issued by the Ecuadorian Ministerio del Ambiente (004-IC-FA-PNY-RSO).

PELOBATES CULTRIPES (Iberian Spadefoot Toad). **MAXIMUM SIZE**. *Pelobates cultripes* occurs in southern France and throughout most of the Iberian Peninsula (Spain and Portugal) (Lizana et al. 1994. J. Herpetol. 28:19–27). De La Vega (1988. Anfibios y Reptiles de la Provincia de Huelva, Ertisa [Ed.]. Huelva, Spain. 238 pp.) reported maximum size as 89 mm SVL. Talavera (1990. Evolución de Pelobatidos y Peloditidos [Amphibia: Anura]: Morfología y Desarrollo del Sistema Esquelético. Unpubl. Ph. D. Thesis, Universidad Complutense de Madrid, Spain.) reported maximum size for females from Madrid, Spain as 101 mm SVL. The record size reported for females is 113 mm SVL (Salvador and García-París 2001. Anfibios Españoles. Identificación, Historia Natural y Distribución. Canseco [Ed.], Talavera de la Reina. 269 pp.). Herein, we report a new maximum size for this species.

On 21 Oct 2002, between 1900–2200 h, we captured three gravid adult female *P. cultripes* that surpassed the previous record length (119 mm SVL, 124 g; 120 mm SVL, 145 g; 125 mm SVL, 168 g) in a temporary pond near Aznalcóllar (Seville Province, Spain, 37º31'N, 6º16'W; 130 m elev.). Each individual was measured in

the field and then carefully released into the pond where they were captured. The terminal phalange of the third digit of the right forefoot was removed for a skeletochronological study to estimate the age of each individual based on successive resting lines in the bone (Hemelaar 1998. J. Herpetol. 22:369–388). The biggest female was five years old, but in the remaining individuals age determination was not possible.

Recently reported geographic variation in body size of *P. cultripes* (Marangoni 2006. Variación clinal en el tamaño del cuerpo a escala microgeográfica en dos especies de anuros [*Pelobates cultripes* y *Bufo calamita*]. Ph.D. Thesis. Univerdidad de Sevilla, Spain), suggests that the differences in body size among different studies could be due to latitudinal variation in body size.

We thank the Consejería de Medio Ambiente de la Junta de Andalucía and the Reserva Biológica de Doñana, for providing the corresponding permits and facilities.

PELOBATES CULTRIPES (Iberian Spadefoot Toad). **PREDATION.** *Pelobates cultripes* occurs in southern France and throughout most of the Iberian Peninsula (Spain and Portugal) (Lizana et al. 1994. J. Herpetol. 28:19–27). In southern Spain, *P. cultripes* breed in a mosaic of small temporary ponds and streams that generally fill with the first autumnal rains in October–November, and dry at the end of May (Tejedo and Reques 2002. *In* Pleguezuelos et al. [eds.], Atlas y Libro Rojo de los Anfibios y Reptiles de España, pp. 94–96. Dirección General de Conservación de la Naturaleza, Madrid). Birds, mammals, and reptiles have been reported as important predators of juvenile and adult *P. cultripes* (Salvador and García-París 2001. Anfibios Españoles. Identificación, Historia Natural y Distribución. Canseco [Ed.], Talavera de la Reina. 269 pp.; Díaz-Paniagua et al. 2005. Los Anfibios de Doñana. Organismo Autónomo Parques Nacionales, Ministerio de Medio Ambiente [Ed.], 181 pp. and references therein). In addition, the snake *Natrix maura* may also be an important predator of this species (Santos 2004. *In* Carrascal and Salvador [eds.], Enciclopedia Virtual de los Vertebrados Españoles. Museo Nacional de Ciencias Naturales, Madrid. http://www.vertebradosibericos.org).

FIG. 1. Ventral side photo of *Pelobates cultripes*, showing three injuries caused by *Natrix maura*. The photo was taken 12 h after the capture.

On 5 Nov 2001 at 1920 h, we observed a gravid female *P. cultripes* being preyed upon by *N. maura* in a temporary pond near Aznalcóllar (Seville Province, Spain, 37º31'N, 6º16'W; 130 m elev.). The middle anterior part of the toad's body was inside the snake's mouth, and only its stomach and legs were visible. The snake was captured and the toad (SVL 79.5 mm, head width 29.5 mm, right hind leg length 92 mm, mass 41.5 g) was photographed and released alive. Injuries were observed on the body of the toad; three on the ventral side (with two apparent bite marks: Fig. 1), and two on the head immediately behind the eyes. The toad died ca. 30 min after capture. We estimated the age of the female (five years old) by skeletochronology (Hemelaar 1998. J. Herpetol. 22:369–388).

The *P. cultripes* (ID AZN2) was deposited in the Estación Biológica de Doñana (CSIC), Seville Province, Spain. We thank the Consejería de Medio Ambiente de la Junta de Andalucía and the Reserva Biológica de Doñana, for providing the corresponding permits and facilities.

PHYSALAEMUS PUSTULOSUS (Tungara Frog). **DISPERSAL**. *Physalaemus pustulosus* is widely distributed along the isthmus of Central America and northern South America through northwestern Venezuela (Ryan 1985. The Tungara Frog: A Study in Sexual Selection and Communication. Univ. Chicago Press, Chicago), and occurs as two disjunct populations on the northern and southern Pacific Coast of Costa Rica, with an approximately 165 km gap between them (N. J. Scott, pers. comm.; Savage 2002. The Amphibians and Reptiles and Costa Rica: a Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago). The northern population occurs in the Tropical Dry Forest of Guanacaste Province and the southern population occurs in the Tropical Moist Forest of the Golfo Dulce region (Holdridge 1967. Life Zone Ecology. Tropical Science Center, San Jose, Costa Rica). The northern population is contiguous with the species' range in Nicaragua, and in the south the population is continuous into Panama and east into South America (Ryan 1985, *op. cit*.). *Physalaemus pustulosus* is a small, conspicuous species as males vocalize loudly in choruses and breed in altered and disturbed habitats including roadside ditches, puddles, ponds, and flooded agricultural fields (Rand 1983. *In* Janzen [ed.], Costa Rica Natural History, pp. 333–335. Univ. Chicago Press; Savage 2002, *op. cit*.).

The apparent Costa Rican gap in distribution has been surveyed periodically since 1964 (Savage and Scott, unpubl.; Bolaños and Chavez, unpubl.) and this species had not been recorded from 1964–2002. I surveyed the south-central Pacific Coast of Costa Rica from Dec 2000–April 2002 from Quepos to Palmar Norte,

and east to San Isidro de El General as part of a herpetological inventory. Herein I report on the expansion of the range of *P. pustulosus* into this gap along the Pacific Coast and the Valle General.

On 12 Jan 2002 I found a small chorus of ca. 5 *P. pustulosus* males calling from a flooded rice field adjacent to the Coastal Highway near Coronado (08º57'99"N, 83º26'60"W; 35 m elev.) after heavy rains. The rice field was ca. 2 ha in size, and water depth ranged from 2 cm at the shore to 0.5 m towards the center of the field, and less than 20 m from the Coastal Highway. This population is ~ 45 km N of the Golfo Dulce populations and is across the large Río Terraba. Six days later on 18 Jan 2002 I found 3 puddles along the Pan American Highway in San Isidro de El General (09º31'97"N, 84º46'51"W; 900 m elev.) with 1–3 male *P. pustulosus* calling. The first puddle was 500 m, the second 1.5 km, and the third 4 km south of San Isidro on the southbound side of the Pan American Highway. There is little forest left in the valley but it is in the Premontane Moist forest. I had surveyed these areas bimonthly from Dec 2000–April 2002 and it was not until Jan 2002 that I encountered this species.

Two major highways, the Pan American Highway and the Coastal Highway, connect this region to the Golfo Dulce and Panama. I suggest that *P. pustulosus* is expanding its range northward in southwestern Costa Rica along trucking routes, possibly as stowaways on commercial trucks shipping agricultural or forest products from the Golfo Dulce region or Panama where this species is known to occur. Savage (2002, *op. cit*.) also reports a "new" population in Siquirres in the Limón Province providing evidence that this species is also invading on the Caribbean versant. Future monitoring along the Coastal Highway north to Quepos may validate my hypothesis that *P. pustulosus* is moving north along trucking routes. It is possible that genetic markers could be used to identify where these "new" populations of *P. pustulosus* originated and the speed at which the species is expanding its range.

This work was supported by Hacienda Baru National Wildlife Refuge, Dominical Costa Rica and Tropical Forestry Initiative through U.S. Forest Service Grant #03-DG-11132762-964. I thank MINAE for providing permits to do field work in Costa Rica, and A. Crawford, A. Rand, and N. Scott for helpful comments on this manuscript.

PROCERATOPHRYS AVELINOI (Cow Frog). **ADVERTISEMENT CALL**. *Proceratophrys avelinoi* was recently described (Barrio and Barrio 1993. Amphibia-Reptilia 14:13–18) and its advertisement call was described by Kwet and Baldo (2003. Amphibia-Reptilia 24:104–107), who classified *P. avelinoi* as rare. Ecological information on advertisement call and reproductive site and seasonality of this species remain little known. Herein I present information on advertisement call and reproduction.

Surveys of calling male *P. avelinoi* were conducted from Sept 2003 to Dec 2004 in Brazil, Paraná state, municipality of São João do Triunfo (25º34'18"S; 50º05'56"W), 780 m elev.. Sites were surveyed two days each month in two fountainheads in Araucaria Forest and two in plantation fields; all sites were ca. 10 m^2. During each visit information was collected on seasonal, daily, and spatial patterns of vocalization and reproduction.

In the Araucaria Forest, *P. avelinoi* could be heard calling all day between September and February. In plantation fields there was only one record of a single male in October 2003. No more than six individuals were heard in the same fountainhead (1–6, N = 36). Individuals were recorded and collected on 25 Oct 2003 by A M X Lima and placed at the Instituto de Pesquisas em Cananéia, Campinas, state of São Paulo (MIPEC 0001; MIPEC 0002). For individuals recorded (N = 7) on 25–26 Oct 2003 (air temp 11–24ºC; water temp 16.5–22ºC), I observed differences in call duration (868–1184 ms at this locality vs. 220–754 ms reported by Kwet and Baldo 2003, *op. cit*.), although there were no differences between SVL, pulse rate, number of pulses/call, or dominant frequency. Distance between calling males was 52–128 cm (N = 26) and no contact interactions were observed. Call site selection was consistent (N = 63), always in the water, and often under or above dead leaves. A mark-recapture effort (toe clipping) was conducted in Sept (N = 11) and Oct (N = 8) 2004, although no individuals were recaptured. Tadpoles were found from October–February in the forest.

The patterns of vocalization, distribution, and tadpole occurrence suggest the species has low density, open populations, with a variable length of advertisement call, and an extended reproductive season (six months) coinciding with the wet season. Although *P. avelinoi* can be found in fountainheads in open areas, reproduction is sensitive to deforestation.

Submitted by **ANDRÉ MAGNANI XAVIER DE LIMA,** Programa de Pós-Graduação em Ecologia e Conservação, UFPR, Brazil. Bento Viana Street, 932, Ap 41. CEP 80210-170, Curitiba, Paraná, Brazil; e-mail: andremxlima@uol.com.br.

PROCERATOPHRYS MELANOPOGON (NCN). **REPRODUCTION.** *Proceratophrys melanopogon* is a little known species of ceratophryine leptodactylid that inhabits the forest floor leaf litter in Atlantic Rainforest areas of southeastern Brazil (Izecksohn et al. 1998. Rev. Univ. Rural, Sér. Ciênc. Vida 20:37–54). Males of this species vocalize near small bodies of water, and tadpoles develop in lentic water at the edges of permanent streams (Izecksohn and Peixoto 1996. Rev. Univ. Rural, Sér. Ciênc. Vida 18:105–107). Little else is known of the biology of this species, which was removed from the synonymy of the morphologically similar *P. appendiculata* (Heyer et al. 1990. Arq. Zool., São Paulo 31:318). On 16 Nov 2005, at 1845 h, a pair of *P. melanopogon* in were collected in axillary amplexus in an area of montane rainforest (22º21'38.5"S, 44º34'14.6"W; 1360 m elev.) located within the Área de Preservação Ambiental (APA) da Serra da Mantiqueira, in Resende municipality, state of Rio de Janeiro, Brazil. The pair (female: SVL 47.6 mm, preserved mass 11.7 g; male: SVL 34.7 mm, preserved mass 4.4 g) was kept in a plastic bag containing a small amount of water and some leaves. The following morning, the female had laid 664 eggs. Upon dissecting the female, we found an additional 78 eggs, indicating that all eggs were not laid at spawning. The frogs were deposited in the Museu Nacional, Rio de Janeiro (MNRJ 40711, male; MNRJ 40712, female).

The total number of eggs (742) reported for the female *P. melanopogon* is within the range (729–946; N = 3) reported by

Boquimpani-Freitas et al. (2002. J. Herpetol. 36:318–322) for the closely-related species *P. appendiculata*. We know of no other published information on fecundity for members of the genus *Proceratophrys*.

We thank Eugênio Izecksohn and Gustavo M. Prado for the identification of the frogs. The Center for Biodiversity Conservation (CCB) of the Conservation International do Brasil and the Conselho Nacional de Desenvolvimento Científico e Tecnológico – CNPq provided financial support for fieldwork at the APA da Serra da Mantiqueira.

PSEUDACRIS REGILLA (Pacific Treefrog). **DEATH FEIGNING**. Anurans commonly employ death feigning (Edmunds 1974. Defense in Animals. Longman, New York, 357 pp.; Pough et al. 1998. Herpetology. Prentice-Hall, Inc. Upper Saddle River, New Jersey. 579 pp.) as an anti-predatory strategy (Zamprogno et al. 1998. Herpetol. Rev. 29:96–97; McCallum et al. 2003. Herpetol. Rev. 34:54–55; Carneiro and Rocha 2005. Herpetol. Rev. 36:301), although this behavior has not been documented in *Pseudacris regilla*. Herein, I report two instances of death feigning in *P. regilla*, a hylid common along the Pacific Coast of USA.

At 1515 h on 7 Aug 2006, an adult *P. regilla* (SVL 38.5 mm, 5 g) was captured underneath a metal grate (34°25'11"N, 119°39'57"W, WGS 84; 233 m elev.) at the Santa Barbara Zoological Gardens, Santa Barbara Co., California. While being handled, the frog abruptly tucked all four limbs in close to the abdomen while lying on its dorsum. I placed the frog onto a table, and the frog remained motionless in this position for ca. 20 seconds. I then turned the frog right side up so that it was sitting on its ventral side. It quickly became alert and active, and attempted to flee. The frog was taken back to the site of capture and released.

At 0900 h on 13 Aug 2006, I captured a smaller adult *P. regilla* (SVL 34.5 mm, 4 g) in the same location. Upon handling, this individual exhibited death-feigning behavior similar to the individual captured six days prior. With all limbs pulled tightly into and underneath the abdomen and its snout tucked tightly into its body, the frog became very rigid. I placed the frog on a table and it remained on its dorsum for ca. 5 min while I photographed it. Afterwards, I turned the frog over onto its abdomen. The frog continued to feign death, remaining motionless with the snout terminus tilted downwards into the body and all four limbs tucked tightly underneath for ca. 20 sec. The frog then raised its head, became alert, and attempted to escape. This individual was also released at the site of capture. To my knowledge, this note represents the first reported case of death feigning in *P. regilla*.

I thank P. Martin and D. Mantooth of the Santa Barbara Zoological Gardens for assistance.

RANA AURORA (Northern Red-legged Frog). **MOVEMENT**. The spatially finite nature of movement studies often imposes the cost-linked restriction that population-level and maximum movement distances will be underestimated (Barrowclough 1978. Bird Banding 49:333–341). Such underestimation, confirmed using molecular methods (e.g., Sumner et al. 2001. Mol. Ecol. 10:1917–1927), may be highest among species with the potential to move the longest distances (i.e., >1 km), since the search area for even a simple radial model increases as no less than the square of the distance, with variation depending on local topography. Based on our previous report of seasonal movement distances up to 2.4 km (Hayes et al. 2001. Herpetol. Rev. 32:35–36), *R. aurora* (*fide* Shaffer et al. 2004. Mol. Ecol. 13:2667–2677) represents an extreme example of this problem. Here, we provide seasonal movement distances for *R. aurora* which much exceed those of our previous report.

Our observations were made during a habitat study of *R. aurora* within the Squaw Flat Research Natural Area (Umpqua National Forest) in the South Umpqua basin, Oregon, USA; a site description is provided elsewhere (Hayes et al., *op. cit.*). Over the interval of May–July 2002, during ca. monthly surveys of the riparian margin of Squaw Creek, we recaptured four adult *R. aurora* at straight-line distances of 4.8, 4.2, 3.5, and 3.7 km from the known breeding pond. These frogs were, respectively, three adult females (102 mm SVL, 84 g; 97 mm SVL, 61 g; 89 mm SVL, 53 g), and an adult male (79 mm SVL, 35 g). All four had been previously marked using PIT tags and had been recaptured or first marked during January–February 2002 surveys of the breeding pond. A fifth frog (also an adult female; 104 mm SVL, 82 g), captured 4.5 km from the breeding pond, may also represent a recapture. However, some uncertainty exists regarding the capture status of this frog, as it was marked with a single toe clip rather than a PIT tag.

The maximum distance reported here doubles that of our earlier report. Longer movements have been reported for other North American ranid frogs, but those consist of recaptures of dispersing juveniles (e.g., Seburn et al. 1997. *In* D. M. Green [ed.], Amphibians in Decline: Canadian Studies of a Global Problem, pp. 64–72. Herpetol. Cons. 1; Funk et al. 2005. Biol. Lett. 1:13–16), between-year recaptures of adults or subadults (e.g., Dole 1971. Copeia 1971:221-228; Reaser and Dexter 1996. Herpetol. Rev. 27:195–196), or annual movement distances estimated from the colonization of habitat in areas where species had been recently introduced (Platz et al. 1990. Copeia 1990:324–333; see Smith and Green 2005. Ecography 28:110–128 for details). The key difference between these reports and ours is that we report adult frog movements within a season. Coupled with our previous report (Hayes et al., *op. cit*), this pattern of movement appears annual, but whether the same individuals move in the same general pattern each year remains unclear. Movement distances for three (and perhaps four) of the frogs we report here match or exceed the seasonal maxima reported for adults of other North American ranid taxa (see especially Bugler et al. 2003. Biol. Cons. 110:85–95; Rathbun and Schneider 2001. Wildl. Soc. Bull. 29:1300–1303; and Smith and Green, *op. cit.*). Although the frogs described here may be approaching the maximum seasonal movement distance for *R. aurora*, Barrowclough's missive (*op. cit.*) about movement distance underestimation remains. Lastly, we recaptured few individuals more than once, so our low within-season recapture reso-

lution may also contribute to underestimating the movement distances of the individuals upon which we report.

The Oregon Zoo Foundation and the US Fish and Wildlife Service provided financial support, and the Oregon Department of Fish and Wildlife provided a scientific handling permit for this work.

RANA BOYLII (Foothill Yellow-legged Frog). **CANNIBALISM AND PREDATION**. Cannibalism has been reported in 12 of 21 families of anurans, including ranids (Crump 1992. *In* Elgar and Crespi [eds], Cannibalism: Evolution Among Diverse Taxa, pp. 256–276. Oxford University Press, Oxford). *Rana boylii* consume a wide variety of invertebrate prey including insects, spiders, centipedes, and water snails, however cannibalism has not been reported (Ashton et al. 1998. Foothill yellow-legged frog (*Rana boylii*) natural history. USDA Forest Service, Pacific Southwest Research Field Station, Arcata, California). Herein, we report two observations of cannibalism in *R. boylii*.

On 8 Sept 2004 at 1300 h an adult *R. boylii* (ca. 50 mm SUL) was observed in a seep 3.0 m from the bank of the South Fork Trinity River near Surprise Creek, Humboldt Co., California (UTM 0452944E; 4515190N; NAD 27 Zone 10). The frog had captured a recently metamorphosed juvenile (ca. 23 mm SUL) conspecific. After the photograph was taken (Fig. 1), the frogs were not captured and were left undisturbed. On 27 Sept 2005 at 1143 h, an adult *Thamnophis couchii* (field no. KDW 243; 46.5 cm SVL; 63.5 cm TL; 39.0 g) was observed along the left bank of Silver Creek, ca. 315 m upstream of the confluence with the South Fork American River (UTM 0709458E; 4296166N; NAD 27 Zone 10; ca. 634 m elev.) within a large aggregation of hibernating ladybird beetles (*Hippodamia convergens*). The snake was noticeably distended and upon palpation, regurgitated an adult female *R. boylii* (California Academy of Sciences [CAS] 233406; 60.0 mm SUL; 26.0 g), which was swallowed legs-first. On 29 Sept 2005, stomach contents of CAS 233406 were examined and included: 6 ladybird beetles (*H. convergens*), one vespid wasp, one tetrigid grasshopper, one spider, one moth, one geometrid caterpillar, one mycetophilid gnat, four *Campanotus* ants, and a juvenile *R. boylii* (17 mm SUL; ca. 1.0 g; Fig. 2).

FIG. 1. Adult *Rana boylii* consuming a juvenile conspecific (Humboldt County, California).

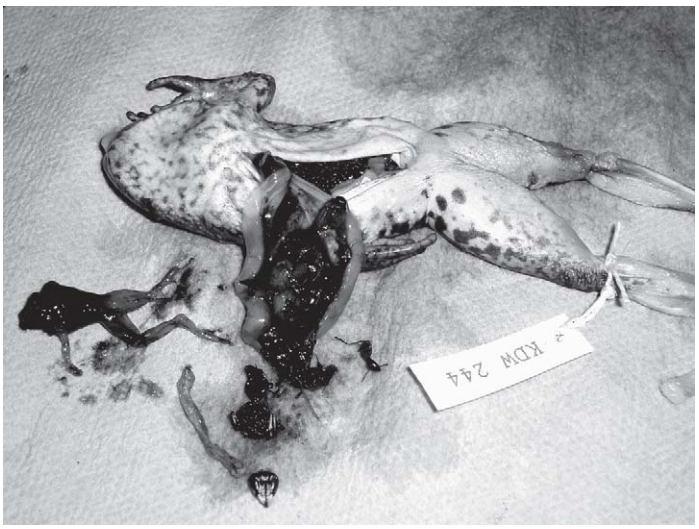

FIG. 2. Stomach contents of CAS 233406 included a juvenile conspecific (El Dorado County, California).

Both observations of cannibalism in *R. boylii* occurred in September, a time when recently-metamorphosed frogs are relatively abundant, and could constitute a significant proportion of the available prey base. On the North Fork Feather River (Butte Co., California) adult female *R. boylii* lose an average 31% of their body mass following oviposition (range 8–46%; N = 52; GANDA, unpubl. data) and the consumption of juvenile conspecifics may help recoup some of this mass in the fall. Given the taxonomic variation of prey found in the Silver Creek frog and that numerous metamorphs were in the immediate vicinity of both observations, cannibalism in *R. boylii* is likely indiscriminate, where juvenile frogs are of appropriate size and elicit a feeding response from adults.

This work was carried out under the FERC 184 hydroelectric project. We thank J. C. Garcia, J. E. Drennan, K. R. Marlow, R. E. Jackman, D. Corcoran, the El Dorado Irrigation District, and M. P. Hayes. Michael Caterino helped with insect identifications. Specimens were collected under California Department of Fish and Game Scientific Collecting Permit no. SC-006634 to KDW.

Submitted by **KEVIN D. WISEMAN**, Garcia and Associates (GANDA), 2601 Mission St., Suite 600, San Francisco, California 94110, USA (e-mail: kwiseman@garciaandassociates.com); and **JAMES BETTASO**, U.S. Fish and Wildlife Service, 1655 Heindon Road, Arcata, California 95521, USA.

RANA CASCADAE (Cascades Frog). **PREDATION**. Because predator/prey relationships are a key factor in food web interac-

FIG. 1. Dragonfly naiad (*Aeshna* sp.) eating a metamorphosing Cascades Frog in the Trinity Alps Wilderness, California. The frog was alive at the time this photograph was taken.

tions, it is important to identify all the species and their role in the ecosystem. Documented invertebrate predators for larval *Rana cascadae* include dragonfly naiads (Jones et al. [eds.] 2005. Amphibians of the Pacific Northwest. Seattle Audubon Society, Seattle, Washington. 227 pp.), beetles (Dytiscidae), and giant water bugs (Belostomatidae) (Peterson and Blaustein 1992. Copeia 1992:577–584). The only documented invertebrate predators of post-metamorphic *R. cascadae* are giant water bugs (Nauman and Dettlaff 1999. Herpetol. Rev. 30:93).

On 10 Oct 2004 at ca. 1500 h, we observed a dragonfly (*Aeshna* sp.) naiad (32 mm TL) consuming a metamorphosing *R. cascadae* (17.5 mm SUL, Gosner Stage 45) in a small spring-fed meadow pond (6.8 m^2, 0.31 m deep) located in the Trinity Alps Wilderness, Trinity Co., California USA (UTM Zone 10, 509661E 4530014N; 2118 m). The naiad's lower mandibles were fastened onto the frog's right hindlimb and its appendages were grasping the frog's body (Fig. 1). The frog was alive and attempting to escape; however its foot, tibia/fibula, and most of the femur of the right hindlimb had been chewed off and presumably eaten. We returned to the pond at ca. 1600 and found the frog dead, half-consumed and floating in the pond. The frog's left forelimb and right hindlimb were completely amputated, a significant portion of its left lateral tissue was removed and the internals were exposed.

This observation extends the reported predation capabilities of naiad dragonflies from tadpoles to metamorphosing *R. cascada*e. There are at least 18 species of Odonata that occur within the Trinity Alps Wilderness area (Pope, unpubl. data). This local diversity suggests that Odonata may be an important natural predator of *R. cascadae* larvae and newly metamorphosed individuals in this area.

Ongoing research on *R. cascadae* ecology has been supported in part by the US Forest Service, California Department of Fish and Game, National Fish and Wildlife Foundation, and Declining Amphibian Populations Task Force.

RANA SPHENOCEPHALA UTRICULARIA (Southern Leopard Frog). **ECTOPARASITES.** Chiggers (Acari: Leeuwenhoekiidae and Trombiculidae) are known to infest a variety of reptile and amphibian species worldwide (Wharton and Fuller 1952. A Manual of the Chiggers. Mere. Entomol. Soc. Washington 4:1–185), yet their occurrence is often overlooked and underreported in the literature. Larvae of the genus *Hannemania* (Leeuwenhoekiidae) parasitize a variety of amphibian species including salamanders, toads, spadefoot toads, tree frogs, and rain frogs (Duszynski and Jones 1973. Int. J. Parasit. 3[4]:531–532; Loomis 1956. Univ. Kansas Sci. Bull. 37, II[19]:1195–1443).

The chigger *Hannemania dunni* was first described as a parasite on the Dusky Salamander (*Desmognathus fuscus*, Sambon 1928. Ann. Trop. Med. Parasitol. 22:67–132). Within Alabama, infestations have only been reported on Southern Two-lined Salamanders (*Eurycea bislineata* = *E. cirrigera*) (Hribar and Tyler 1989. Melsheimer Entomol. Ser. No. 37:28). We present here the first report of *H. dunni* in the Southern Leopard Frog (*Rana sphenocephala utricularia*) and provide the second documented occurrence of this parasite in Alabama.

Three adult Southern Leopard Frogs were encountered under a section of log on a sandbar thickly vegetated with Water Willow (*Justicia americana*) in Big Canoe Creek near Ashville, St. Clair County, Alabama, USA (33°50'25"N, 86°16'11"W WGS84/NAD83) on 14 Oct 2005. Two of the frogs were captured and upon close examination numerous orange subcutaneous lesions were apparent on the ventral surface, especially the ventral and posterior aspects of the thighs and the interdigital webbing. These frogs were collected and transported back to Auburn University.

The frogs were euthanized on 17 Oct 2005 with benzocaine. The frogs had 16 and 29 lesions on their ventral surfaces. Eleven mites (two from the first host and nine from the second) were removed from these lesions using fine-tipped forceps. The frogs were formalin fixed and deposited in the Auburn University Museum of Natural History Collection (AUM 37280–37281). Mites were cleared in Andre's Fluid (1/3 glacial acetic acid, 1/3 chloral hydrate, and 1/3 water), and preserved by slide mounting in Hoyer's Medium (50 ml distilled water, 30 g gum Arabic, 200 g chloral hydrate, 20 ml glycerin; Krantz 1978. A Manual of Aracology. OSU Bookstores Inc., Corvallis, Oregon 335 pp.). They were identified to genus using Brennan and Goff (1977. J. Parasitol. 63:554–566) and to species using Loomis (1956, *op. cit.*) by examination under a light microscope. Voucher specimens of the *Hannemania dunni* are deposited in the Florida State Collection of Arthropods Gainesville (E2006-881-1).

RANA SYLVATICA (Wood Frog). **PREDATION**. Much information exists on the role of predation in the larval ecology of *Rana sylvatica* (Wellborn et al. 1996. Ann. Rev. Ecol. Syst. 27:337–363; Wilbur 1972. Ecology 53:3–21), but little data exist on specific predators of adult Wood Frogs (Muths et al. 2005. http://

www.fs.fed.us/r2/projects/scp/assessments/woodfrog.pdf). During Spring and Summer 2003 we radiotracked 43 Wood Frogs in southern Maine for an average of 25.6 days each. Wood Frogs were tracked using 0.9 g external transmitters attached with a soft rubber belt (Baldwin et al. 2006. J. Herpetol. 40:443–454). During this time, 15 frog remains were found, and 12 deaths (27.9% of tracked frogs) were attributed to vertebrate predation. Of these, three were confirmed Common Gartersnake (*Thamnophis sirtalis*) predation, and three were suspected to be raptor predation. An additional six events showed signs of predation or consumption but could not be traced to a specific predator. All snake predation events occurred during the post-breeding, springtime emigration period (3 May; 18 June; 23 June), while raptor predation overlapped temporally and continued into midsummer (7 June; 19 June; 14 July).

Garter snake predation occurred in or on the margins of breeding pools and neighboring forested wetlands. One snake carrying a frog and transmitter was captured while it was swimming in a vernal pool within 2 m of the last location of the frog (previous day). Another was tracked to a sphagnum hummock in a large forested wetland where the Wood Frog had migrated following breeding. The third garter snake was tracked to an upland refuge under a log and dry leaves, 13 m from the pool margin where the Wood Frog was located 4 days earlier. Two of the snakes were held in captivity and excreted the Wood Frog transmitters within 1 week of capture.

Raptor predation was inferred from semiarboreal locations and conditions of the carcasses. In one instance the transmitter was recovered from an oak tree (*Quercus* sp.), 2 m from the ground, adjacent to a mossy stream bank in which the frog had been located the previous day. The carcass had been largely stripped of flesh, leaving the belt, transmitter, and bones. A second carcass was found on top of a *Tsuga canadensis* snag, 2.3 m from the ground, inside a forested wetland and 21 m from the previous location. The carcass was relatively fresh with only the head consumed. The third attributed to a raptor was found 4 m from its previous location on top of a sphagnum hummock in a forested wetland, with sharp incisions near the base of the hind legs and a portion of its skull removed. The 6 events that were not attributed to a specific predator occurred terrestrially, and involved crushing-type wounds suggestive of those caused by a mammal (e.g., fox, skunk, raccoon).

Vernal pools are threatened ecosystems, widely recognized for their value as important amphibian breeding habitat (Comer et al. 2005. http://cheetah.natureserve.org/library/isolated_wetlands_05/isolated_wetlands.pdf). Our observations suggest that vernal pools also play a significant role in the local ecology of terrestrial forest food webs.

RANA SYLVATICA (Wood Frog). **PREDATION**. I observed the predation of an adult *Rana sylvatica* by a giant water bug (*Lethocerus* sp.) in a vernal pool in Shapleigh, Maine, USA (43°30'32.3"N, 70°46'33.4"W). On 15 April 2006, in a small (<0.1 ha) vernal pool containing Red Maple (*Acer rubrum*) hummocks, calls emitted on various pitches attracted my attention to a Wood Frog attempting to haul itself out of the water onto a small floating log, while being clasped at the waist level by a giant water bug. The giant water bug's rostrum appeared to be inserted near the base of the spine. During a period of ca. 3 min., the frog was partly pulled back in the water, its upper body gradually tilted forward until the snout was just under the surface. Over this period the calls became progressively shorter in duration and volume, until the frog was flat on the water surface, motionless and silent.

Giant water bugs have been observed preying on adults of two species of anurans, *Rana cascadae* (Nauman and Dettlaff 1999. Herpetol. Rev. 30:93) and *Bufo terrestris* (McCoy 2003. Herpetol. Rev. 34:135–136). This observation provides evidence for another interaction, part of the complex ecology of vernal pools.

Submitted by **FREDERIC BEAUDRY**, Department of Wildlife Ecology, 5755 Nutting Hall, University of Maine, Orono, Maine 04469-5755, USA; e-mail: frederic.beaudry@umit.maine.edu.

RANA YAVAPAIENSIS (Lowland Leopard Frog). **LARVAL CANNIBALISM.** *Rana yavapaiensis* is known to oviposit primarily in late winter-spring, with a smaller pulse of oviposition in early fall (Sartorius and Rosen 2000. Southwest. Nat. 45:267–273). Large tadpoles sometimes overwinter (Collins and Lewis 1979. Southwest. Nat. 24:371–373). These observations occurred during winter 2005–06 in a semi-natural, urban backyard pond (3 × 4 m, 0.4 m deep), which had a self-sustaining frog population derived from three southeastern Arizona populations. In monitoring the fourth of eight egg masses deposited in February–early March 2006, I noted 5–6 large tadpoles (5.5–7.5 cm LOA) from a single September 2005 clutch active around and under the egg mass, which had just begun to hatch on 5 March. On 7 March, closer inspection of the fifth egg mass, which was estimated to be at Gosner stages 16–19 and predicted to be 50% hatched on 9 March, revealed 12–18 large tadpoles (of an estimated 48+ present in the pond) active under, around, and on the egg mass. Tadpoles were swimming lazily, pushing into the mass with actively moving mouthparts and, in at least one case observed to swallow a dislodged embryo. Water was 11 cm deep at the mass, which was about 8 cm diameter, temperature was 17ºC (range 13–20ºC over 24 h). The mass contained an estimated 1100 eggs based on previous counts of hatchlings in clutches of similar size; 30 h later there were only 18 developing ova remaining, the egg mass was reduced in size but not dissociating as expected post-hatching, and no hatchlings were observed near the egg mass site, as would normally be seen. Other egg masses appeared to be less affected in proportion to the depth of water column below them, with hatchlings seen around all of them, and there was less activity of large tadpoles near them. However, the eighth and deepest-water egg mass, which hatched last (15 March), attracted about 15 large tadpoles on the bottom where a cone of detaching hatchlings from

it would likely fall. Five of these tadpoles transferred to a screened-in observation tray with 10 hatchlings apparently consumed four hatchlings in a 24 h period.

The frog and tadpole densities involved here are similar to the highest Lowland Leopard Frog abundances I have observed in Arizona and Sonora during 1983–2005, and the only other vertebrate in the pond is the Gila Topminnow (*Poeciliopsis occidentalis*). An accumulating literature on oophagy, larvivory, and cannibalism in tadpoles (Gunzberger and Travis 2005. J. Herpetol. 39:457–571), and their occurrence in species with generalized tadpoles such as *R. yavapaiensis* and the American Bullfrog (*R. catesbeiana*; Kiesecker and Blaustein 1997. Ecology 78:1752–1760) may support suggestions in McDiarmid and Altig (1999. Tadpoles: The Biology of Amphibian Larvae, pp. 218, 246) that these might be widespread and ecologically important phenomena.

Submitted by **PHILIP C. ROSEN**, School of Natural Resources, University of Arizona, Tucson Arizona 85721, USA; e-mail: pcrosen@u.arizona.edu.

SCINAX FUSCOVARIUS (Snouted Treefrog). **DEATH FEIGNING**. Posturing is often important in defense (Ducey and Brodie 1991. Herpetologica 47:89–95). Death feigning or thanatosis is widespread in amphibians (Duellman and Trueb 1994. Biology of Amphibians. John Hopkins Univ. Press, Baltimore and London), mainly among frogs (Azevedo-Ramos 1995.Rev. Bras. Biol. 55:45–47). *Scinax fuscovarius* occurs in south, southern, and central Brazil as well as in the eastern regions of Argentina, Paraguay, and Bolivia (Kwet and Di-bernardo 1999. Amphibians. Edipucrs, Porto Alegre). On 4 Jan 2006 at 1839 h in Poxoréu municipality (54º24'W; 15º51'S), Mato Grosso state, Brazil, we found an adult male *S. fuscovarius* (46 mm SVL) resting ca. 0.5 m above the ground on a shrub. When we approached, the frog jumped to the ground and remained motionless with the head tipped downward and eyes closed for two minutes. When DJR captured the treefrog, it jumped from his hand and fell to the ground in a death feigning position with the dorsum on the ground and the limbs close to the body. This behavior protects vulnerable parts of the body, and sometimes creates an impression of bigger size. This is the first report of death feigning in *S. fuscovarius.*

We are grateful to M. Menin, V. Pazin, K. Mokross, and R. Arruda for suggestions, and to CNPq for scholarships to DJR.

Submitted by **DOMINGOS J. RODRIGUES**, Coordenação de Pesquisas em Ecologia, Instituto Nacional de Pesquisas da Amazônia, CP 478, CEP: 69011-970, Manaus, AM, Brazil (e-mail: poxo@inpa.gov.br); and **VALÉRIA ARAÚJO BRAULE PINTO RODRIGUES,** Coordenação de Pesquisas em Entomologia, Instituto Nacional de Pesquisas da Amazônia, CP 478, CEP: 69011-970, Manaus, AM, Brazil (e-mail: araujobp@inpa.gov.br).

SCINAX TRAPICHEIROI (NCN). **PREDATION**. Although most adult viperid snakes consume predominantly warm-blooded prey, juvenile viperids commonly prey on frogs (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill. New York. 670 pp.; Martins et al. 2002. *In* Campbell and Brodie [eds.], Biology of the Vipers, pp. 307–328. Eagle Mountain Publishing, Utah). Some invertebrates are also important predators of frogs, although crustaceans have rarely been reported to prey on such animals (Duellman and Trueb 1986, *op. cit.*; Toledo 2005. Herpetol. Rev. 36:395–400). Here we describe two cases of predation on the treefrog *Scinax trapicheiroi* in an Atlantic rainforest area—one by the viperid snake *Bothrops jararaca* and the other by the freshwater shrimp *Macrobrachium carcinus.* Both predators, and their prey, were deposited at the Museu Nacional, Rio de Janeiro (MNRJ).

On 29 Oct 2004, at night, during fieldwork at a creek near Vila Dois Rios (23°12'S, 44°13'W), on Ilha Grande island, State of Rio de Janeiro, Brazil, we collected a juvenile Jararaca Lancehead (*Bothrops jararaca;* MNRJ 12663) (SVL 232.3 mm; tail 50.6 mm), that was resting on a branch 1.88 m above the ground. It was transferred to a cloth bag where it regurgitated a partly digested adult male *S. trapicheiroi*. *Bothrops jararaca* has been reported to prey on other hylids (*Scinax fuscovarius*, *Hyla leucopygia*, and *H. prasina*; Sazima 1992. *In* Campbell and Brodie [eds.], Biology of the Pitvipers, pp. 199–216. Selva Press, Tyler, Texas), but this is the first report of *S. trapicheiroi* as prey.

During Feb 2005, at night, during an anuran mark-recapture study at the same creek, after we released an adult male *S. trapicheiroi* on a rock, it jumped into the water, being promptly captured by the freshwater shrimp (*Macrobrachium carcinus*; body size 83.3 mm, MNRJ 19524) which started to consume it. Before the shrimp had finished eating, we collected and placed it (and its prey) in a plastic bag with water. Inside the bag, the shrimp finished consuming the frog. *Scinax trapicheiroi* are known to release their eggs in lentic water (Rico et al. 2004. Amphibia-Reptilia 25:277–286) and thus predation by aquatic invertebrates might be relatively common.

This note suggests that *Bothrops jararaca* and freshwater shrimp might be important sources of mortality for *S. trapicheiroi* at Ilha Grande, because of their abundance in the area.

We are grateful to Davor Vrcibradic for helpful comments, and to Fausto M. da Silva and Carolina Tavares for the identification of the shrimp.

Submited by **VITOR NELSON TEIXEIRA BORGES-JÚNIOR, LÍVIA DE OLIVEIRA GIL, CARLOS FREDERICO DUARTE DA ROCHA,** and **MONIQUE VAN SLUYS**, Departamento de Ecologia, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Rj, Brazil, CEP 20550-019.

SPEA HAMMONDII (Western Spadefoot). **REPRODUCTIVE PATTERN.** It is known that breeding congregations of *Spea hammondii* quickly assemble in response to heavy rainfall that triggers emergence, saturates the soil, and fills ephemeral breeding pools (Storer 1925. Univ. California Publ. Zool. 27:153–163; Morey 2005. *In* Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 514–517. Univ. California Press, Berkeley, California). Breeding records are strongly correlated with regional rainfall patterns; consequently, breeding generally occurs from January through May (Stebbins 2003. Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts; Storer 1925, *op. cit.*) with a peak in activity, most years, during the months of February and March (Brown 1976. Contrib. Sci., Los Angeles Co. Mus. Nat. Hist. 286:11; Morey 2005, *op. cit.*).

On 12 Aug 2005, *S. hammondii* larvae (N = 30) (4–10 mm TL)

were collected from an excavated unshaded temporary pond (ca. 7 m × 11 m, 0.5 m deep) located within a Redshank Chaparral plant community (*Adenostoma fasciculatum, A. sparsifolium, Arctostaphylos* spp., *Ceanothus* spp., *Quercus dumosa, Rhus ovata*) in Tierra Del Sol, San Diego Co., California, USA (T17S, R6E, Sec. 35; ca. 1160 m elev.). Because of the size range of the larvae, we inferred that breeding likely took place during or shortly after a storm on 1 Aug 2005 that resulted in 1.4 cm of rainfall. A series of preserved larvae (N = 14) was deposited in the herpetological collection of the California Academy of Science (CAS 233766).

Opportunistic breeding as a reproductive pattern is defined by the ability to breed throughout the year and often is a strategy used by species from arid regions characterized by uncertain rainfall, with heavy rainfall being the most common cue to initiate reproductive behavior (Duellman and Trueb 1986. The Biology of Amphibians. John Hopkins Univ. Press, Baltimore, Maryland; Long 1989. J. Herpetol. 23:176–179). Because *S. hammondii* has the ability to breed shortly after emerging from aestivation, and has been documented to breed in at least 11 months of the year (Brown 1976, *op. cit.*; Ervin et al. 2005. Herpetol. Rev. 36:309–310; this report), the species clearly demonstrates the characteristics of an opportunistic breeder. Based on this new information, *S. hammondii* should be recognized as a species that generally breeds from January through May, as well as being an opportunistic breeder (*sensu stricto*) that is physiologically capable of breeding any time of the year given favorable environmental conditions.

Our thanks to J. Vindum of California Academy of Sciences for providing museum numbers, and to Roland Sosa for making useful comments on this manuscript. *Spea hammondii* larvae were collected under California Dept. Fish and Game permit number 5399 issued to ELE.

Submitted by **EDWARD L. ERVIN**, Merkel and Associates, Inc., 5434 Ruffin Road, San Diego, California 92123, USA (e-mail: eervin@merkelinc.com); and **TIMOTHY L. CASS**, 3573 Niblick Drive, La Mesa, California 91941, USA.

SPEA HAMMONDII (Western Spadefoot). **PREDATION.** *Spea hammondii* is an aquatic breeding terrestrial anuran. Although highly nocturnal, occasionally it remains active into daylight hours while in amplexus (Storer 1925. Univ. California Publ. Zool. 27:153–163; E. Ervin, pers. obs.).

An increase in predation risk has been demonstrated for aquatic breeding terrestrial species during breeding periods because of a combination of factors, including increased density, increased activity levels, and spawning pairs occupying aquatic sites into daylight hours (Beebee 1996. Conservation and Ecology of Amphibians, Chapman and Hall, UK; Stebbins and Cohen 1995. The Natural History of Amphibians. Princeton Univ. Press, Princeton, New Jersey).

Amphibians, reptiles, wading and passerine birds, and mammals are known to prey on transformed individual *Spea* (see individual species accounts in Lannoo [ed.] 2005. Amphibian Declines, The Conservation Status of United States Species. Univ. California Press, Berkeley, California). The only cases of predation on transformed *S. hammondii* individuals we are aware of are the Two-striped Gartersnake, *Thamnophis hammondii* (Ervin and Fisher 2001. Herpetol. Rev. 32:265–266) and the introduced American Bullfrog, *Rana catesbeiana* (Hayes and Warner 1985. Herpetol. Rev. 16:109; Morey and Guinn 1992. *In* Williams et al. [eds.], Endangered and Sensitive Species of the San Joaquin Valley, California, pp. 149–158. Wildlife Soc., Western Section, Sacramento, California; Balfour and Ranlett 2006. Herpetol. Rev. 37:212).

Because there are no previous reports of predation on transformed *S. hammondii* by any bird or mammal species the following accounts are notable. On 27 Sept 1997 (1250 h), JPP discovered the remains of two adult *S. hammondii*; two heads with intact skin (1F:1M), on the bank of an ephemeral pool (10.5 m × 15.25 m, 70 cm deep) in the headwaters of Temecula Creek, Dodge Valley, San Diego Co., California (33.362°N, 117.756°W, 955 m elev.). The only fresh animal sign left by the predator were raccoon tracks at the place the remains were observed.

On 27 April 1998 (ca. 1600 h), DSJ observed three desiccated adult (1F:2M) *S. hammondii* at the entrance of a burrow occupied by a pair of Burrowing Owls (*Athene cunicularia*) at Naval Air Station Lemoore, near Lemoore, Kings Co., California (36.3565°N, 119.9335°W, 66.4 m elev.). The carcasses were wholly intact; mouths stretched open, less their fleshy tongues. In addition to a single Burrowing Owl observed active at the burrow, owl pellets were present at the top of the mound located adjacent to the burrow.

On 24 Feb 2004 (1505 h), AKG and ELE collected the remains of two adult *S. hammondii* from the bank of an ephemeral pool (18 m × 5 m, 25 cm deep) in Escondido, San Diego Co., California (33.12005°N, 117.11745°W, 237 m elev.). The remains were found within an area of ca. $1m^2$. The disarticulated remains consisted of two skulls with intact skin (1F:1M), two complete stomachs, two fat body clusters, as well as sections and pieces of large and small intestines, fat body clusters, livers, and oviducts containing ova. Because of the lack of direct observation and no fresh animal sign found, it is unclear what preyed on the adult *S. hammondii*. In this observation, we rule out raptors as the predator for the following reasons: Typical raptor predatory behavior, based on raptor predation sequence observations, including those based on adult spadefoots, report that the raptors often fly to a more secure place after the capture of their prey (Mills 1977. Wilson Bull. 89[4]:623; Sexton and Marion 1974. Wilson Bull. 86[2]:167–168). In addition, we are unaware of discussions that have identified diagnostic physical characteristics that would enable us to reliably determine whether the predator was either avian or mammalian by reexamining the physical remains (e.g., intact heads, limbs, viscera).

To our knowledge, this is the first report of avian and mammalian predation on adult *S. hammondii*. Specific details suggest that the *S. hammondii* remains collected in 1997 and 2004 were preyed on as amplexing pairs. At each of the sites, individuals collected consisted of one male and one female (determined by degree and pattern of vocal sac pigmentation), the male and female remains were generally found in the same area, and the pool contained *S. hammondii* egg clusters < 24 h old (pre neural folds; pre Gosner Stage 14). Consequently, our observations support the idea that aquatic breeding terrestrial anurans might be at greater risk of predation while at their breeding habitat and while engaged in amplexus.

We thank M. R. Jennings and S. R. Morey for suggestions that improved the manuscript. *Spea hammondii* specimens were sal-

vaged under California Department of Fish and Game collecting permit issued to ELE and AKG. Remains were preserved in 70% ethanol and are retained by ELE for further study.

STEFANIA WOODLEYI (Woodley's Treefrog). **DEFENSIVE BEHAVIOR.** Antipredator strategy and defensive behavior is widespread among anurans, the most common being crypsis, mimicry, thanatosis (death feigning), toxicity, Unken reflex, and other defensive postures (Duellman and Trueb 1994. Biology of Amphibians, The Johns Hopkins University Press, Baltimore and London, 670 pp.; Zug et al. 2001. Herpetology – An Introductory Biology of Amphibians and Reptiles, 2nd Ed., Academic Press, San Diego, California, 630 pp.). Aggressive response to a potential predator, unrelated to parental care, is less typical. This behavior includes gaping, jumping towards the potential predator with mouth wide open, sometimes with the emission of a distress call, and occasionally biting (Duellman and Trueb 1994, *op. cit.*; Fabrezi and Emerson 2003. J. Zool., Lond. 260:41–51; Myers 1966. Herpetologica 22:68–71; Veloso 1977. Herpetologica 33:434–442; Zweifel 1972. Bull. Am. Mus. Nat. Hist. 148:1–140). Most frogs exhibiting this behavior are stout-bodied and some have fang-like teeth (Fabrezi and Emerson 2003, *op. cit.*).

We collected 14 specimens of the poorly known cryptobatrachid *Stefania woodleyi* in Kaieteur National Park, west-central Guyana. *Stefania woodleyi* is endemic to the southern Pakaraima region, Guyana (Señaris and MacCulloch 2005. Bull. Biol. Soc. Washington 13:9–23), and little is known about its ecology (MacCulloch and Lathrop 2002. Herpetologica 58:327–346). One of these specimens, IRSNB 13799, a male SVL 45.8 mm, collected 25 March 2006 at 2130 h, in the vicinity of Elinkwa River in the southeastern part of the park (5°09'46"N, 59°24'01"W; 550 m elev.) displayed an aggressive defensive behavior on two occasions. When first captured, and later while being photographed, the frog suddenly inflated its lungs, opened its mouth wide and jumped toward the handler's hand while emitting a single high-pitched catlike "meow" distress call. The defensive mechanism was similar to an attempt to bite the handler's hand. The first "attack" was so surprising that the handler almost released the frog. Three other specimens from the same locality also displayed the same behavior with some variation. IRSNB 13801, a male SVL 47.3 mm collected 23 June 2006 at 2230 h only inflated its lungs and opened its mouth without jumping, emitting any distress call and/or attempting to "bite". IRSNB 13802, a female SVL 58.2 mm collected 26 June 2006 at 2130 h several times displayed the same aggressive defensive behavior as IRSNB 13799 and IRSNB 13803, a juvenile SVL 26.8 mm also displayed, but a single time only, the complete aggressive defensive behavior. This indicates that both sexes and juveniles display this defensive mechanism.

There is much intraspecific variation in defensive behaviors (Myers 1966, *op. cit.*), which may be influenced by ecological factors (Gomes et al. 2002. Copeia 2002:994–1005). Interestingly, only some of the *S. woodleyi* collected in Kaieteur National Park displayed this aggressive antipredator mechanism and all of them were collected at the same locality, in the vicinity of Elinkwa River. As far as we know, this is the first report of aggressive defensive behavior within the genus *Stefania* and within the family Cryptobatrachidae. Unlike most anuran taxa that exhibit this type of behavior, *Stefania* are gracile, and lack fang-like teeth. Specimens are deposited in the herpetological collections of the Institut Royal des Sciences Naturelles de Belgique (IRSNB), Brussels, Belgium.

We thank the Belgian Directorate-General of Development Cooperation for financial support, G. Seegobin for field assistance, and R. MacCulloch (Royal Ontario Museum, Canada) for reviewing the manuscript. Permission to conduct the herpetofaunal surveys was granted by the Prime Minister of Guyana, the Honorable Samuel Hinds, and S. Nokta and I. Nathoo of the Guyana National Parks Commission. Research and collection permits 180604BR011 and 030605BR006 were issued by the Guyana Environmental Protection Agency.

XENOPUS LAEVIS (African Clawed Frog). **PREDATION.** Observations of predation on *Xenopus laevis* by fish, birds, and otter have been documented in native and feral populations (Lobos et al. 2005. Biodivers. Conserv. 14:429–439; McCoid 1980. Bull. South. California Acad. Sci. 79[2]:82–86; Tinsley et al. 1996. *In* Tinsley and Kobel [eds.], The Biology of *Xenopus*, pp. 35–59). Virtually no information exists on predation of clawed frogs by invertebrates. Here we provide field observations of predation by crabs on adult *X. laevis* in South Africa.

We observed *X. laevis* in South Africa, Mpumalanga province (previous NE-Transvaal), Hoedspruit district, at the "Torchwood Pond" (24°25'S; 30°50'E). The pond was 65 m^2 in size, fed with crystal clear water by a perennial mountain torrent, and located on the wooded slopes of the Drakensberg Mountains at 750 m elev. The pond harbored a native population of about 80–100 *X. laevis* and ca. 20–30 river crabs, *Potamonautus* sp. (Decapoda: Potamonautidae).

On 2 Feb 1996 at 0045 h, while we were observing *Xenopus* with the aid of a flashlight, a hand-sized crab was spotted at a depth of about 60 cm, holding a female *Xenopus* (ca. 80 mm SVL) in its claws. The frog was fixed by the claws at the head and at the left hind leg and was almost unable to move. The crab was feeding using its mandibles at the frog's left lateral side, and had produced an injury about 15 mm. Small motions of the forelegs and the right hind leg of *Xenopus* indicated that it was still alive. Probably disturbed by the flashlight, the crab moved backward under the rotten leaf litter.

A similar case of predation was observed on 7 Feb 1996 at 2200 h at a depth of 40 cm. Two hand-sized crabs were observed feeding on a female *Xenopus* (ca. 70 mm SVL). One of the crabs had

grasped the head of the female, the second crab grasped one hind leg. The frog had large wounds at the eye region and at its shank, but still showed some motion. Checking the site about 10 min later, both crabs and the body of the frog had disappeared.

We never directly observed a crab catching a clawed frog successfully. But we often observed grasping movements of the crabs when frogs came close. A male (SVL 67 mm) and a female (SVL 88 mm) frog have been observed being grasped by crabs at the hind legs, but escaped. We also found two other *Xenopus*, a male (SVL 62 mm) and a female (SVL 96 mm), with wounds at the hind legs consistent with attack by crabs.

GYMNOPHIONA

GYMNOPIS MULTIPLICATA (Purple Caecilian). **PREDATION.** The natural predators of *Gymnopis multiplicata* are relatively unknown and the diet of *Micrurus mipartitus* is assumed to be other snakes (Guyer and Donnelly 2005. Pp. 228-229 *in* Amphibians and Reptiles of La Selva, Costa Rica, and the Caribbean Slope). Here I report on predation by *M. mipartitus* on *G. multiplicata* from the La Selva Biological Station, Heredia Province, Costa Rica. On 15 Oct 2005 at 2105 h, I observed an adult *M. mipartitus* (ca. SVL 80 cm) consuming an adult *G. multiplicata* (ca. SVL 35 cm; Fig. 1). This interaction was observed on the ground adjacent to the Sendero Sura trail between 200 and 250 m elevation. To the best of my knowledge, this represents the first report of a predator for *G. multiplicata* and the second report of a prey item for *M. mipartitus*.

FIG. 1. Predation by an adult *Micrurus mipartitus* on an adult *Gymnopis multiplicata* at La Selva Biological Station, Costa Rica.

TESTUDINES

ERETMOCHELYS IMBRICATA (Hawksbill), ***CHELONIA MYDAS*** (Green), and ***CARETTA CARETTA*** (Loggerhead) Seaturtles. **EPIZOANS**. The Columbus Crab, *Planes* sp., is a common epizoan of oceanic stage (juvenile) Loggerhead Seaturtles (*Caretta caretta*) in the southwestern Atlantic. Columbus or Swimming Crabs, including *Planes minutus*, *P. cyaneus*, and *P. marinus*, are essentially oceanic species rarely found near the coast (Davenport. 1992. J. Mar. Biol. Ass. U.K. 77:611–620), and occur on both natural and artificial floating material (Chace 1951. Proc. U.S. Nat. Mus. 101:65–103; Dellinger et al. 1997. J. Mar. Biol. Ass. U.K. 77:185-194). Columbus Crabs occurred with 83% of southwestern Atlantic juvenile Loggerheads (Carranza et al. 2004. Mar. Turtle Newsl. 102:5–7), 82% of those found off Madeira Island (Dellinger et al. 1997, *op. cit.*), and 27% from the Mediterranean (Casale et al. 2004. J. Mar. Biol. Ass. U.K. 84:1005–1006).

On the other hand, Columbus Crabs rarely are reported to associate with other sea turtle species. Columbus Crabs were scantly reported for the Olive Ridley Seaturtle, *Lepidochelys olivacea*, in Playon de Mexiquillo, Pacific coast of Mexico (Díaz et al. 1992. Publ. Soc. Herpetol. Mex. 1:19–25) and Chile (Miranda and Moreno. 2002. Rev. Biol. Mar. Oceanogr. 37:145–146), both pertaining to *P. minutus*, while off La Jolla, California, (Hubbs 1977. California Fish Game 63:263–267) and Jalisco, Mexico (Hernandez-Vazquez and Valadez-Gonzales 1998. Cienc. Mar. 24:119–125) they pertain to *P. cyaneus*. For the Hawksbill Seaturtle, *Eretmochelys imbricata*, Chace (1951, *op. cit.*) reported *P. minutus* from Rhode Island turtles and *P. cyaneus* from Baja California, while Schärer (2003. Rev. Biol. Trop. 51:87–89) reported only 3 out of 105 Hawksbills to be associated with *P. minutus* in Puerto Rico. Schärer (2003, *op. cit.*) found them associated with small turtles, and argue they were probably arriving from a pelagic habitat. For Green Seaturtles, *Chelonia mydas*, *P. cyaneus* was recorded by Crane (1937. *apud* Chace 1951, *op. cit.*) in Baja California, by Chace (1951, *op. cit.*) in Acapulco, Santa Inez Bay, Mexico, in the Galápagos Islands, by Brown and Brown (1995. *In* K.A. Bjorndal [ed.], Biology and Conservation of Sea Turtles, pp. 235–240. Smithsonian Institution Press, Washington, D.C.) in Peru, by Wickstein and Behrens (2000. SCAMIT Newsl. 19:7) in California, and by Green (1998. NOAA Tech. Memo. 412:63) who reported 'small crabs hiding among algae' on Galápagos Green Seaturtles, which could be Columbus Crabs.

Planes cyaneus and *P. marinus* are the species that occur in the southwestern Atlantic (Juanicó 1976. Dusenia 9:145–150; Spivak and Bas 1999. J Crustacean Biol. 19:72–76; Prado and Melo 2002. Crustaceana 75:579–595), but only the former was reported as a commensal of Loggerhead Seaturtles by Carranza et al. (2003, *op. cit.*). During 2005 we found Columbus Crabs associated with Hawksbill, Green, and Loggerhead turtles and report these findings here. Crabs were identified according to Chace (1951, *op. cit.*) and Spivak and Bas (1999, *op. cit.*) and all belong to *P. cyaneus*. Records for each turtle species are given in detail below.

A juvenile Hawksbill Seaturtle (Curved Carapace Length, CCL

= 39 cm, Curved Carapace Width-CCW = 33.5 cm) was captured by handnet on 19 January 2005 off southern Brazil (27.76°S, 46.80°W) over waters ca. 1500 m in depth. Five *P. cyaneus* were found, one male with Curved Carapace Length-CL = 11.3 mm, and four females CL = 10.8, 11.4, 12.6, and 12.9 mm. The largest female was gravid and the smallest one had an autotomy at the base of the left chelae. In addition, 1 remora, *Remora* sp., and 1 Goose Barnacle, *Lepas anserifera*, were found on the turtle.

A juvenile Green Seaturtle (CCL = 40.7 cm, CCW = 37.1 cm) was captured by gillnet on 18 February 2005 off southern Brazil (29.06°S, 49.24°W) over waters 35 m deep. One gravid female crab was found (CL = 16.3 mm).

During three cruises on a pelagic longline vessel carried out in January, July, and August 2005, Columbus Crabs were found on 18 Loggerhead Turtles incidentally captured. Capture locations were between 27.51 and 33.77°S, and 44.88 and 50.28°W, over waters 266–4600 m deep. Turtle CCL ranged from 49 to 97 cm (mean = 61.3 cm). Only one female with CCL of 97 cm was adult based on minimum CCL of nesting females of 83 cm in Espírito Santo, southeastern Brazil (Baptistote et al. 2003. Chel. Conserv. Biol. 4:523–529). All others were immature in their pelagic stage. A total of 32 *P. cyaneus* were collected (mean 1.8 crabs per turtle, min = 1, max = 3), of which 16 were male and 16 female, which does not differ from the expected 1:1 ratio reported for the genus (Dellinger et al. 1997, *op. cit.;* Spivak and Bas 1999, *op. cit.*; Carranza et al. 2003, *op. cit.*). Crab measurements - CL and Carapace Width CW (mean ± 1 SD, minimum-maximum), in mm, were: males CL - 15.6 ± 3.7, 9.3–21.3, CW - 15.6 ± 3.6, 9.3–21.3, N = 16; ovigerous females CL - 17.4 ± 3.1, 12.7–20.7, CW - 17.5 ± 3.0, 12.9–21.1, N = 7; nongravid females CL - 13.9 ± 3.7, 10.1–22.0, CW - 14.0 ± 3.7, 9.8–22.2, N = 9. CL and CW of gravid females were significantly larger than that of nongravid (Mann-Whitey U = 13, p = 0.05, both CL and CW); males and females (gravid and nongravid pooled) did not differ in CL and CW (Mann-Whitney test U = 119, p = 0.73 and U = 123.5, p = 0.87, respectively). The 22% of crabs with pereiopod autotomy was similar to 25% reported for *P. minutus* in Madeira Is. (Dellinger et. al. 1997, *op. cit.*) and lower than 45% reported for *P. marinus* in Argentina (Spivak and Bas 1999, *op. cit.*).

The scarcity of records of *Planes* spp. on adult Loggerheads or on other sea turtle species could be related to the preference of Columbus Crabs for deep waters as opposed to the shallow habitats used by all nesting turtles, and large immature Green and Hawksbill Seaturtles. However, because of opportunistic commensalisms with crabs, all hard-shelled turtles are equally prone to being colonized by crabs when in deep waters, as shown by this study.

GRAPTEMYS GIBBONSI (Pascagoula Map Turtle). **DIET.** *Graptemys pulchra* (*sensu lato*) was originally described as inhabiting coastal rivers of the Gulf of Mexico from the Pearl River drainage in Louisiana to the Yellow River in Florida and south Alabama (Lovich 1985. Cat. Amer. Amphib. Rept. 360.1). However, based on morphological data, Lovich and McCoy (1992. Ann. Carnegie Mus. 61:293–315) split *G. pulchra* into three distinct species by describing two new species, *G. gibbonsi* and *G. ernsti*. The *pulchra* clade, at the time comprised of only *G. pulchra* and *G. barbouri*, was considered by McKown (1972. Phylogenetic Relationships within the Turtle Genera *Graptemys* and *Malaclemys*. Unpubl. Ph.D. dissertation, University of Texas, Austin) to be part of the "broad-headed" group. The larger head width in this clade compared to other *Graptemys* species was thought to be an adaptation for consuming mollusks (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 578 pp.; Lindeman 2000. Biol. J. Linn. Soc. 69:549–576).

G*raptemys gibbonsi* inhabits the Pearl and Pascagoula River drainages in Mississippi and Louisiana. Since its split from *G. pulchra*, there has been little ecological research conducted on the species, especially on feeding ecology. Prior to the recognition of *G. gibbonsi*, Cagle (1952. Copeia 1952:223–234) reported fragments of clams and snails in the stomach of one juvenile female *G. pulchra* (now *G. gibbonsi*) from the Pearl River. On 18 April 2006, we witnessed the capture of a large female *G. gibbonsi* by a local fisherman using hook and line baited with chicken liver at the MS Hwy 42 boat ramp on the Leaf River near the confluence of the Bouie River (31°20'562"N, 89°16'855"W [WGS84]). We acquired and transported the individual to the laboratory for blood collection and held the individual in a cooler over night prior to its release. During that time, the individual defecated 56 fragments of *Corbicula fluminea* ranging from 2 to 17.7 mm (mean = 9.24 mm, SD = 4.23 mm) in length. This is the first observation of *Corbicula* in the diet of *G. gibbonsi* from either the Pearl or Pascagoula River basins. This is not an aberrant report for the *pulchra* clade, as *Corbicula* has been documented in the diets of other species: *G. barbouri* (Sanderson 1974. Unpublished master's thesis, University of South Florida, Tampa); and *G. ernsti* and *G. pulchra* (Shealy 1976. Bull. Florida St. Mus. 21:47–111).

The research that led to this observation was being conducted under Mississippi Administrative Scientific Research Collection Permit for collection of *G. flavimaculata* and *G. gibbonsi* for hormone and genetic analysis. We thank Jon Davenport for reviewing this document.

Submitted by **JOSHUA R. ENNEN**, **WILL SELMAN**, and **BRIAN R. KREISER**, Department of Biological Sciences, University of Southern Mississippi, 118 College Drive #5018, Hattiesburg, Mississippi 39406-0001, USA (e-mail: joshua.ennen@usm.edu).

MACROCHELYS TEMMINCKII (Alligator Snapping Turtle). **REPRODUCTION.** *Macrochelys temminckii* is considered a valuable commodity in portions of the United States, leading to potential overexploitation of the species (Sloan and Lovich 1995. Chelon. Cons. Biol. 1:221–222; Pritchard 1989. The Alligator Snapping Turtle: Biology and Conservation. Milwaukee Publ. Mus. 104 pp.).

TABLE 1. Temperatures (°C) of an Alligator Snapping Turtle (*Macrochelys temminckii*) nest during Summer 2005, in Faulkner County, Arkansas.

Time Period	Mean	Maximum	Minimum
11–25 Jun	24.2	28.1	21.0
26 Jun–10 Jul	25.4	28.7	23.2
11–25 Jul	26.1	29.8	23.2
26 Jul–9 Aug	26.1	30.5	23.5
10–20 Aug	26.5	28.7	24.8

Conservation planning will require life history information from throughout the species' range. Apparently, there are no published reports on the nesting habits of *M. temminckii* in Arkansas.

On 9 June 2005, a nest of *Macrochelys temminckii* was discovered on a southeast-facing bank (35°10.229'N, 92°19.020'W) of Cadron Creek in Faulkner Co., Arkansas, USA. The nest, located 2.8 m from the water, was situated on a small ledge devoid of vegetation. The flask-shaped nest had a maximum diameter of 20 cm and a depth of 17 cm. Thirty-six spherical eggs were excavated from the nest and measured. Egg mass ranged from 21.0 to 24.7 g (mean = 22.7 g). Egg diameter ranged from 33.2–35.5 mm (mean = 34.4 mm). The eggs were subsequently reburied to incubate under natural conditions, with a temperature-sensitive data logger placed in the center of the nest to record hourly nest temperatures. Nest temperatures are reported in Table 1. The nest was checked on 20 August and 25 eggs and the data logger were retrieved; of the remaining 11 eggs left in the nest, external appearance suggested that 9 were unfertile and 2 were fertile. Incubation of the 25 collected eggs continued in the laboratory at 29°C for the duration of development. Thirteen eggs hatched from 23 to 28 September. The remaining 12 unhatched eggs were dissected and found to be infertile.

Hatchling morphometrics were recorded within 12 h of hatching. Hatchling mass ranged from 12.0–15.4 g (mean = 13.8 g). Carapace length varied from 33.2–37.7 mm (mean = 35.7 mm) while carapace width ranged from 30.6–34.3 mm (mean = 33.0 mm). Plastron length ranged from 22.1–25.7 mm (mean = 23.8 mm) and plastron width ranged from 12.0–17.2 mm (mean = 15.2 mm).

Scientific collecting permits were obtained from the Arkansas Game and Fish Commission prior to commencement of the study. An Institutional Animal Care and Use Protocol was issued by the University of Central Arkansas.

RHINOCLEMMYS PUNCTULARIA (Spot-legged Wood Turtle). **REPRODUCTION.** *Rhinoclemmys p. punctularia* is a semi-aquatic geoemydid turtle found in Trinidad, eastern Venezuela, French Guiana, and northern Brazil (Pritchard and Trebbau 1984. Turtles of Venezuela. SSAR Contr. Herpetol. 2:1–403; Ernst and Barbour 1989. Turtles of the World. Smithsonian Inst. Press, 313 pp.). The exact distribution and habitat requirements of this turtle need further study but it apparently inhabit igarapés (small rivers) and tributaries (Vogt et al. 2001. Biodiversidade e Funções Ecológicas dos Ecossitemas, ISA). The reproductive behaviors of this species are not well known, but clutches generally consist of one or two large eggs that are deposited on the ground in depressions or under leaf litter. (Pritchard and Trebbau, *op. cit.*; Ernst and Barbour, *op. cit.*).

Copulation of two specimens at Maranhão, Brazil, was observed in July 1997, at about 1030 h, on a cloudy day with an ambient temperature of 23°C. The duration of copulation was undetermined. The female weighed 1400 g, the male 700 g. In January 1998 (182 days after the observed copulation), a nest of three eggs (possibly a product of the observed copulation) was found in tall grass near the water reserve of the habitat. Two of the eggs were standing up and the third on its side. They were slightly elongated and had a white-yellowish coloration. The eggs ranged from 59.6 to 63.6 mm (mean 61 ± 2.2 mm) long and 29.9–30.5 mm (mean 30.3 ± 0.3 mm) wide. Egg mass was 32.2–36.5 g (mean 34.4 ± 2.2 g). The eggs were incubated in the laboratory and in April 1998, 90 days after the nest was found, a single egg hatched. The hatchling had a mass of 16 g, the carapace was 46 mm long and 37 mm wide, and the plastron was 46 mm long and 30 mm wide. On the next day another egg hatched, but the hatchling had a malformed carapace and plastron. The third egg was lost to an apparent fungus infestation. Clutch size reported here is the same as that from a captive specimen in a zoo in Guiana (Pritchard 1979. Encyclopedia of Turtles, TFH, Inc., Neptune, New Jersey. 895 pp.) and confirms that *R. punctularia* clutch size is small, but the eggs are relatively large.

Submitted by **SILVIA REGINA TRAVAGLIA CARDOSO**, Lab. de Herpetologia, Instituto Butantan, Av. Vital Brazil, 1500, CEP 05503-900, São Paulo, SP, Brazil; e-mail: silviacardoso@butantan.gov.br.

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). **PREDATION**. Predation on waterfowl and other birds by Common Snapping Turtles (*Chelydra serpentina*) is well known, but avian predation by other aquatic turtles is rarely reported (Pryor 1996. Wilson Bull. 108:190–192; Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, D.C.). Here I report an observation of predation of an adult passerine by aquatic emydid turtles.

At approximately 1400 h on 31 May 2002, an agonistic encounter was observed between two adult male Red-winged Blackbirds (*Agelaius phoeniceus*) on the surface of a small pond in Greer Co., Oklahoma, USA. Three adult *Trachemys scripta elegans* were observed swimming toward the two birds. When the turtles got within ca. 3 m, one of the birds flew away. The second bird stayed on the surface of the water with wings spread and beak agape, apparently exhausted. A third male blackbird attacked the water-bound male, but retreated almost immediately, perhaps after noticing the turtles nearby. After the second aggressor retreated all three turtles disappeared beneath the water, and seconds later the remaining blackbird disappeared as well. An incomplete bird carcass floated back to the surface less than a minute after being pulled under water, and the turtles were not observed again.

With the exception of waterfowl, predation of adult birds by turtles is apparently an unusual and opportunistic event. The fact that three turtles were involved likely does not necessarily suggest cooperation, but is perhaps an indication of the high densities of *T. scripta* in this and other nearby ponds

I thank Joy Yoshioka and Wesley Webb for assistance in the field, and Oklahoma Department of Corrections for access to the ponds where the above observations were made.

SERPENTES

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). **BEHAVIOR**. *Agkistrodon piscivorus leucostoma* is highly nocturnal during summer months in the Missouri Ozarks (Johnson 2000. The Amphibians and Reptiles of Missouri. Missouri Department of Conservation, Jefferson City. 339 pp.). Aggregations of *A. p. leucostoma* have been documented denning (Dundee and Burger 1948. Nat. Hist. Misc. 21:1–2) and feeding (Keiser 1993. Herpetol. Rev. 24:34), but not basking.

On 12 August 2004 we observed an aggregation of three similar-sized *A. p. leucostoma* basking on the root system of an overturned tree located on a gravel-bar, near the shoreline of the North Fork of the White River, Ozark Co., Missouri. The root system extended about 0.5 m in height above the gravel-bar and had been invaded by vegetation along one side, creating sun mosaics within the lower portions. The three snakes were coiled and basking on the top of the root system. Two recently shed individuals flashed their mouths and retreated into a more secure area within the root system upon disturbance. On 14 August 2004, five individuals were observed on the same root system. Two snakes on top had just shed and were coiled over the body of a third. The two remaining snakes had opaque eyes and were lower, coiled within the root system in dappled sunlight. Both observations occurred at ca. 1500 h on overcast days with high temperatures of 20°C (below the average daytime high temperature for August of 27°C). Based on size, all of these snakes appeared to be about two years old (MAN, unpubl. data). We did not observe any abundant food source, thus there was no indication that these were feeding aggregations. We made more diurnal observations of cottonmouths on these two days (eight observations) than were made over 179 days during a survey in the same area (MAN, unpubl. data).

Funding was provided by the Saint Louis Zoological Park and the Reptile and Amphibian Conservation Corps.

Submitted by **JOSEPH J. TAVANO**, **AMBER L. PITT**, and **MAX A. NICKERSON** (e-mail: maxn@flmnh.ufl.edu), University of Florida, Florida Museum of Natural History, PO Box 117800, Gainesville, Florida 32611-7800, USA.

AGKISTRODON PISCIVORUS PISCIVORUS (Eastern Cottonmouth). **PREDATION**. Numerous avian predators, primarily wading birds and raptors, are known to feed on juvenile *Agkistrodon piscivorus* (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex: A Monographic Review. SSAR, Oxford, Ohio. 614 pp., and references therein; Ernst 1992. Venomous Reptiles of North America. Smithsonian Institution Press, Washington, D.C., 236 pp.; Mitchell 1994. Reptiles of Virginia. Smithsonian Institution Press, Washington, D.C., 352 pp.). Here, we provide the first report of juvenile *A. p. piscivorus* predation by a passerine.

On 14 March 2006 at 1640 h, while driving on a dirt road within the Donnelly Wildlife Management Area (WMA), Colleton Co., South Carolina, USA, we encountered an adult crow (*Corvus* sp.) subduing a juvenile *A. p. piscivorus* (273 mm SVL, 326 mm TL) on the road edge adjacent to a large pond (32°41'48"N, 80°36'12"W). The crow was manipulating the snake by the head with its bill, but upon our approach released the snake and flew to a nearby tree. The snake suffered trauma to its head, particularly the left eye and jaw, and within ca. 10 min of our arrival the snake died. The fresh condition of the snake, the limited road traffic in the WMA, and the absence of any trauma normally associated with road injuries (e.g., crushed body, torn skin, viscera protruding from mouth or vent) suggested that the snake had been killed by the crow. A bulge in the snake's abdomen indicated the animal had recently eaten, and palpation of the stomach contents revealed a partially digested frog (likely *Rana clamitans*), which had been swallowed head-first. Voucher photographs of the snake and frog were deposited in the Campbell Museum, Clemson University, Clemson, South Carolina (CUSC 2314).

Birds of the family Corvidae (jays and crows) are generalist predators that feed on a variety of vertebrates, including snakes (Bent 1947. Life Histories of North American Birds. Jays, Crows, and Titmice. Bull. 191, U.S. Nat. Mus, Washington, D.C., pp. 226–257). Thus, predation of juvenile cottonmouths by large corvids such as crows is not unexpected.

We thank Stanlee Miller of the Campbell Museum, Clemson University for archiving voucher materials.

WELCH**, Department of Forestry and Natural Resources, Clemson University, Clemson, South Carolina 29634, USA; and **STEVEN G. PLATT**, Department of Biology, Box C-64, Sul Ross State University, Alpine, Texas 79832, USA.

AGKISTRODON PISCIVOROUS PISCIVOROUS (Eastern Cottonmouth). **BRUMATION.** *Agkistrodon piscivorous* is one of the last snakes to begin brumation in our area, sometimes waiting until the first heavy frost of winter to move to higher ground to hibernate in stumps (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex. A Monographic Review. SSAR, Oxford, Ohio. 614 pp.). Between ca. 1245 h and 1345 h on 27 November 2005, three *A. piscivorous* were seen on the grounds of the Sumter High School Environmental Education Center (33°53.748'N 80°23.604'W), Sumter, South Carolina, USA. The first was a juvenile perched ca. 1.5 m above the water line on the steep bank of a free flowing ditch. The snake fled into the bank when approached. The second snake was a larger female (1030 mm SVL, 590 g)

found coiled on the northwest side of a small island under an observation tower. The third snake was a smaller female (760 mm SVL, 426 g) found on a moderately traveled path on an east-facing bank.

The latter two snakes did not flee when approached. The location of these two snakes was checked daily at ca. 1430 h and their location and position noted. During the observation period (27 November 2005 to 21 December 2005) both snakes remained exposed in the same general location (within 2 m^2 of the original location). Sometimes the snakes were found coiled and sometimes stretched out. The average temperature during this time was 9.6°C with frost events occurring on 2, 6, 10, 11, 13, and 20 December (total time below freezing was ca. 52 h over the observation period). During the measuring process neither snake displayed defensive behaviors. Head tracking was observed, but the snakes did not vibrate their tails, gape their mouths, musk, or assume defensive coils. The second snake was last observed at 1045 h on 21 December 2005. She swam away at a moderate speed upon approach (water temperature 6.2°C). The third snake was last observed at 1730 h partially submerged in the water (5.9°C).

Previous records of *A. piscivorous* activity in December (Gloyd and Conant, *op. cit.*) have attributed their presence to unusually warm periods in winter. This is obviously not the case here. The presence of *A. piscivorous* in December following six frost events suggests that these snakes may be more cold tolerant than previously thought. There may also be a bioenergetic advantage to female snakes that can tolerate colder temperatures. Zaidan et. al. (2003. Copeia 2003:231–240) noted that parturition in *A. piscivorous* occurs in August or September, potentially leaving a short time for the snake to prepare energetically for brumation. Females that are capable of foraging at colder temperatures would then have a selective advantage over the snakes that entered brumation earlier. There could be, however, an energetic disadvantage to snakes that are active too late into the colder months (M. Dorcas, pers. comm.) because of their inability to properly digest food items at cold temperatures.

ALSOPHIS PORTORICENSIS ANEGADAE (Puerto Rican Racer). **SCAVENGING**. Evidence for scavenging by pit vipers and aquatic species continues to accumulate (DeVault and Krochmal 2002. Herpetologica 58:429–436), but cases of terrestrial colubrids feeding on carrion are much less common. On 23 September 2005 at 1150 h we captured a male *Alsophis portoricensis angadae* (560 mm SVL, 82.5 g) within a hotel complex (18.4793ºN, 64.5781ºW) on Guana Island, British Virgin Islands. It had recently ingested a relatively large food item of unusually angular shape, which we obtained by forced regurgitation (Fig. 1). The ejected food items consisted of two chicken bones (a humerus weighing about 5 g and about half of an ulna, weighing about 1 g) which we deposited in the Yale Peabody Museum (YPM F-4171-2). The snake was released at the site of capture. Chicken wings are provided to workers at a construction site located about 70 m from the capture site and leftovers are often discarded in the nearby brush. Based on the state of digestion, which had left few traces of meat on the bones, the snake had likely encountered the bones very recently. *Anolis cristatellus*, a major component of the diet of the racer, is abundant at the site, thus lack of food is unlikely to have been a factor. Although scavenging is not a large part of the diet of *A. portoricensis*, this observation suggests that some snake species have greater dietary flexibility than often believed.

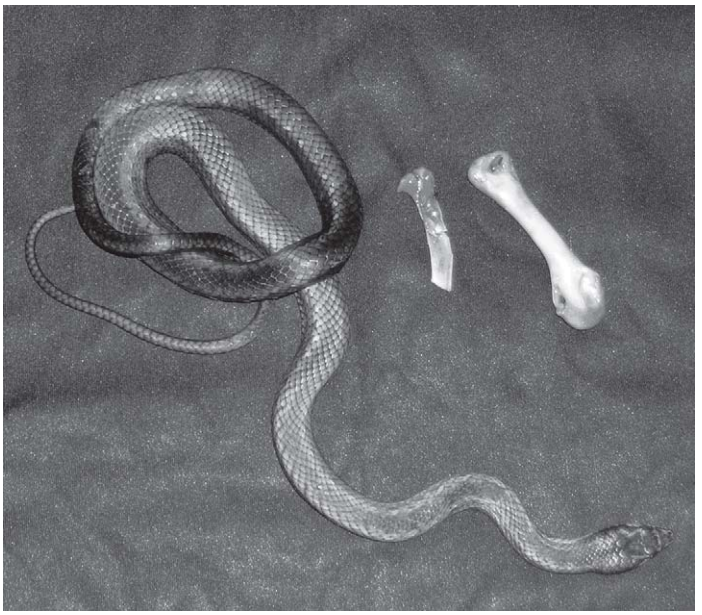

FIG. 1. *Alsophis portoricensis* and chicken bones it regurgitated.

CLELIA RUSTICA (NCN). **REPRODUCTION**. Maximum clutch size for *Clelia rustica* is reported as eight eggs (Achaval 1973. Trab. V. Congr. Latinoam. Zool. 1:17–29; Vaz-Ferreira et al. 1973. Trab. V Congr. Latinoam. Zool. 1:232–244; Cei 1993. Mus. Reg. Sci. Nat. Torino 14:1–949). An adult specimen collected 19 December 2004 at Parque Rivera (Departamento Montevideo, Uruguay) laid thirteen eggs (mean dimensions = 41 × 22 mm, mean mass = 11.72 g) on 27 December 2004. Twelve neonates (mean SVL = 257.9 mm; mean mass = 7.49 g) hatched after 68–71 days of incubation. Two specimens were sacrificed and along with the unhatched egg were deposited in Colección Zoología Vertebrados, Reptiles (ZVC-R), Facultad de Ciencias, Montevideo (ZVC-R 6300-6302).

Submitted by **SANTIAGO CARREIRA** (e-mail: carreira@fcien.edu.uy) and **SILVANA BALETTA** (e-mail: silvana@serpentario.edu.uy), Sección Zoología Vertebrados, Facultad de Ciencias, Iguá 4225, CP 11400, Montevideo, Uruguay.

COLUBER CONSTRICTOR MORMON (Western Yellow-bellied Racer). **CANNIBALISM**. Cannibalism has been reported for multiple subspecies of racers including *C. c. constrictor* (Conant 1938. Amer. Midl. Nat. 20:53), *C. c. priapus* (Hamilton and Pollack 1956. Ecology 37:519–526; Jackson 1971. J. Herpetol. 5:196), and *C. c. flaviventris* (Fitch 1963. Univ. Kansas Publ. Mus. Nat. Hist. 15:351–468). Here, we report cannibalism by *C. c. mormon*. On 21 August 2006 at 1810 h, we encountered an adult (678 mm SVL) *C. c. mormon* in the act of ingesting another snake (headfirst) on a hillside adjacent to Greenwood State Beach, Mendocino Co., California, USA (39º07'40"N, 123º42'56"W). Approximately 10 cm of the ingested snake's tail protruded from the mouth of the predator and was securely wrapped around a poison oak (*Toxicodendron diversilobum*) stem, deterring further ingestion. The predator vigorously struggled to pull the snake's tail free, but was unsuccessful. After 15 min, we carefully extracted the racer from among the dense vegetation to obtain a body measurement and voucher photograph. In doing so, the ingested snake, still secured to the plant stem by its tail, was released from the racer's grasp and pulled completely free from the racer's gut. The partially ingested snake was an apparently unharmed (no visible bite marks) *C. c. mormon* (436 mm SVL) and was immediately active and seemingly alert upon removal from the larger racer. Voucher photographs of the two snakes were taken (CUSC 2348; Campbell Museum, Clemson University) and both snakes were released at the capture site. Cunningham (1959 Herpetologica. 15:17–19) reported consumption of conspecifics by captive *C. c. mormon*, but to our knowledge this is the first reported observation of cannibalism by this species in the wild.

We thank Stanlee Miller of the Campbell Museum, Clemson University for archiving the voucher photographs.

Submitted by **THOMAS R. RAINWATER**, The Institute of Environmental and Human Health, Texas Tech University, P.O. Box 764, Jefferson, Texas 75657, USA (e-mail: thomas.rainwater@tiehh.ttu.edu); **KATHERINE E. CROTALUS AQUILUS (Queretaran Dusky Rattlesnake). **MAXIMUM SIZE**. The maximum total length recorded for *Crotalus aquilus* is 678 mm, but most adults are less than 500 mm (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York. 870 pp.). During July and August of 2006 we measured three adult male *C. aquilus* that exceed the previously reported maximum size. All three were found near Acambay, Estado de México, México at an elevation of ca. 2510 m. We preserved a male captured on 12 July 2006 with a total length of 681 mm (618 mm SVL, 63 mm tail length, 237.3 g). This specimen was deposited in the herpetological collection of the Museo de Zoología de la Facultad de Ciencias at the Universidad Nacional Autónoma de México (MZFC 19258). Additional males captured on 5 August 2006 (619 mm SVL, 66 mm tail length, 203.4 g) and 6 August 2006 (633 mm SVL, 61 mm tail length, 230.7 g) also exceeded the previously reported maximum length. Because three of 17 male *C. aquilus* exceeded the recorded maximum length, we suggest that animals of this size are not unusual at this location.

CROTALUS AQUILUS (Queretaran Dusky Rattlesnake). **MORTALITY**. In México, forest fires follow one of two seasonal patterns. In most of the country, the fire season runs from January to June, but in northeastern México the fire season begins in May and ends in September. Both fire seasons coincide with the dry season (SEMARNAP 2000. Texto Guía Forestal. Subsecretaría de Recursos Naturales, Dirección General Forestal-SEMARNAP. México, D.F., 150 pp.). Forest fires have the potential to negatively affect forest faunas, and in particular, amphibians and reptiles (Bury 2004. Conserv. Biol. 18:968–975). Fire-induced formation of light gaps in forest canopies can favor certain reptiles, but reptiles may also have greater difficulty finding refuge in fire-affected sites (Bury, *op. cit*.; Ernst et al. 1995. Herpetol. Rev. 26:185–187). However, few data exist indicating the vulnerability of reptiles in Mexico. Hence, here we provide an observation from the Mexican state of Hidalgo suggesting that *Crotalus aquilus* may sometimes be at risk from fires.

During a visit to the state of Hidalgo at 0030 h on 16 July 2005, we found a *C. aquilus* in an area known as El Calicanto at kilometer 13.5 on Highway 105 between Pachuca and Tampico, municipality of Mineral del Chico (20º09'01"N, 98º40'51"W, elev. 2590 m, NAD27). The area lies in the Sierra de Pachuca and has a mixed oak (*Quercus*) forest vegetation with *Q. laurina*, *Q. affinis*, *Q. mexicana*, and *Pinus teocote* present. The snake, a juvenile female (270 mm SVL; 18 mm tail length), died a few days later. The tail, which was missing the rattle, appeared burned to a distance 22 mm anterior to the vent, and displayed wrinkled and infected tissue dorsally. Although we did not weigh the snake, she appeared emaciated.

During 12–23 June 2005, a forest fire had swept through this entire area (Jimenez-Rosenberg et al. 2004. Biodiversitas 52:1–10). The appearance of the snake suggested that it was either exposed to fire directly or to a hot substrate. Our visit to the site occurred about a month after the fire, and we suggest that this animal survived the fire but succumbed from fire-related injuries.

The *C. aquilus* (ITAH1278) was deposited in the herpetological collection of the Instituto Tecnologico Agropecuario de Hidalgo, Mexico.

CROTALUS AQUILUS (Queretaran Dusky Rattlesnake). **REPRODUCTION**. Published reports of litter size in *Crotalus aquilus* are few, although Armstrong and Murphy (1979. The Natural History of Mexican Rattlesnakes. Univ. Kansas Mus. Nat. Hist. Spec. Publ. 5:1–88) reported that litter size ranged from 6–7 young that ranged in size from 153–177 mm SVL. On 03 March 2004 a gravid female *C. aquilus* (459 mm SLV, 139.55 g) was collected by Jessica Cortes, in Cerro del Tenayo, Estado de México, México. She was maintained in captivity (Laboratorio de Herpetología de la Facultad de Estudios Superiores Iztacala, UNAM) on a diet of mice. On 26 March she gave birth to six live offspring. The neonates averaged 161.3 ± 6.0 (range 134–177) mm SVL and 4.8 ± 0.3 g (range 4.4–5.1) g in mass. Relative clutch mass (Vitt and Price 1982. Herpetologica 38:237–255) was 0.271.

CROTALUS MOLOSSUS MOLOSSUS (Northern Black-tailed Rattlesnake). **DIET.** Many snake species are known to prey upon bats, primarily by capturing them while they are roosting, although some snakes capture flying bats that are either emerging or returning from roosts or while the bats are foraging (Hutson et al. 2000. Microchiropteran bats. IUCN Global Status and Conservation Action Plan. IUCN/SSC Chiroptera Specialist Group. IUCN, Gland, Switzerland). The only rattlesnakes known to prey on bats are *Crotalus helleri* and *C. horridus* (Klauber 1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind, Second Edition. University of California Press, Berkeley, California; Uhler et al. 1939. *In* Transactions of the Fourth North American Wildlife Conference, pp. 605–622. Washington, D.C.). Here we report an instance of predation by *Crotalus m. molossus* on Pallid Bats (*Antrozous pallidus*). At ca. 0200 h on 17 September 2006, in Brewster Co., Texas, USA (NAD 1927, 029°39'N, 103°06'W, ca. 742 m elev.), we watched an adult *C. m. molossus* striking at Pallid Bats flying in and out of a roadway bridge. A small colony of bats were roosting in the internal structure of the bridge. The snake was positioned on the bridge at the edge of the pavement with its anterior extended into the air near where the bats were flying in and out of the culvert. We captured the snake and palpated a single recently ingested bat from its stomach. Lumps present in the snake (but not palpated) suggest additional recently ingested food items.

CROTALUS WILLARDI AMABILIS (Del Nido Ridge-nosed Rattlesnake). **DIET**. The diet of *Crotalus willardi* is known to include mice, lizards, centipedes, and birds (Holycross et al. 2002. *In* Schuett et al. [eds.], Biology of the Vipers, pp. 243–252. Eagle Mountain Publishing, Eagle Mountain, Utah). However, there are only a few diet records for *Crotalus willardi amabilis*. These include a Southern Pocket Gopher, *Thomomys umbrinus* (Bryson and Holycross 2001. Herpetol. Rev. 32:262), the mention of a rodent in one stomach (Smith et al. 2005. Bull. Chicago Herpetol. Soc. 40:210), and mention of unidentified rodent hairs in the scat of wild specimens (Armstrong and Murphy 1979. The Natural History of Mexican Rattlesnakes. Univ. Kansas Mus. Nat. Hist. Special Publ. 5:1–88).

Here we report the presence of an adult squirrel (*Tamias dorsalis*) in the stomach of an adult female *C. w. amabilis* (Colección de Anfibios y Reptiles del Laboratorio de Ecología de la Unidad de Biología, Tecnología y Prototipos, LE-UBIPRO 14490). The snake was collected 21 September 2005 at the bottom of a deep canyon near the crest of the Sierra del Nido, Chihuahua (29º29'37.7"N, 106º43'21.8"W, 2550 m elev.). The squirrel was at least twice the normal diameter of the snake's body.

We thank David Armstrong for identifying the squirrel.

CROTALUS WILLARDI (Ridge-nosed Rattlesnake). **REPRODUCTION**. On 8 August 2004, one of us (KS) encountered a gravid female *Crotalus willardi* (453 mm SVL, 43 mm tail length, 99.1 g) in the northern Sierra San Luis, Sonora, México (31º17.2'N, 108º46.2'W, 2104 m elev.). Surrounding habitat consists of young oak woodland-scrub regenerating from a 1989 wildfire. The female was maintained in captivity until parturition on 30 August 2004. On the morning of 30 August, the female gave birth to four live healthy neonates, and a single live deformed neonate. The four healthy neonates were measured, weighed and sexed (172, 181, 172, 176 mm SVL; 5.5, 6.8, 6.1, 6.2 g; sex male, male, female, female). The deformed neonate was eyeless, smaller than siblings, had failed to completely absorb available yolk prior to birth, weighed 4.1 g, and died soon after birth. The female weighed 63.5 g immediately following parturition. Relative clutch mass (including 1.9 g of undigested yolk) was 0.31. This litter was born later in the year than all but one previously reported parturition event (Holycross and Goldberg 2001. Copeia 2001:473–481). Clutch size and neonate sizes fall within previously reported ranges (Holycross and Goldberg, *op. cit.*)

We thank the Rocky Mountain Research Station, U.S. Forest Service for funding.

Submitted by **ESTRELLA MOCIÑO DELOYA**, Departamento de Biología Evolutiva, Facultad de Ciencias, Universidad Nacional Autónoma de México. A.P. 70-399 C.P. 04510. México. D.F. CROTALUS WILLARDI (Ridge-nosed rattlesnake) **DIET.** *Crotalus willardi* are known to consume small mammals, lizards, centipedes, and birds (Holycross et al. 2002. *In* Schuett et al. [eds.], Biology of the Vipers, pp. 243–252. Eagle Mountain Publishing, Eagle Mountain, Utah). To date, only six accounts of avian prey items have been recorded from the diet of *C. willardi*, five from *C. w. obscurus* in the Animas Mountains and the Sierra San Luis (Holycross et al., *op. cit.*), and an additional record from *C. w. willardi* in the Huachuca Mountains (Parker and Stotz 1997. Bull. Maryland Herpetol. Soc. 13:123). Three of these prey items were identified to species, all small passerines; *Aimophila ruficeps*, *Myadestes townsendi*, and *Wilsonia pusilla* (Parker and Stotz, *op. cit.*; Holycross et al., *op. cit.*).

Here we report another observation of avian predation by *C. willardi*. At 1640 h on 4 October 2003, one of us (EMD) observed an adult female *C. willardi* (465 mm SVL, 78.8 g) attempting to ingest an adult male Hermit Thrush (*Catharus guttatus*) (30.1 mm tarsus length, 101.6 mm wing chord length, 153 mm total length). The snake was found beneath a manzanita shrub within a meter of a small pool of a mostly dry intermittent stream in the northern Sierra San Luis (Chihuahua, México; 31°17.3'N 108° 45.5'W, 2068 m elev.). The snake regurgitated the thrush when we disturbed it. However, because the widest part of the bird's body had already been ingested, we believe the snake would have been able to completely swallow the bird had it not been disturbed. Feces obtained while processing this snake contained feathers, suggesting that the snake had consumed a bird prior to the witnessed attempt. The thrush was deposited in the Colección de Aves of the Museo de Zoología de la Facultad de Ciencias, Universidad Nacional Autónoma de México (MZFC 19304).

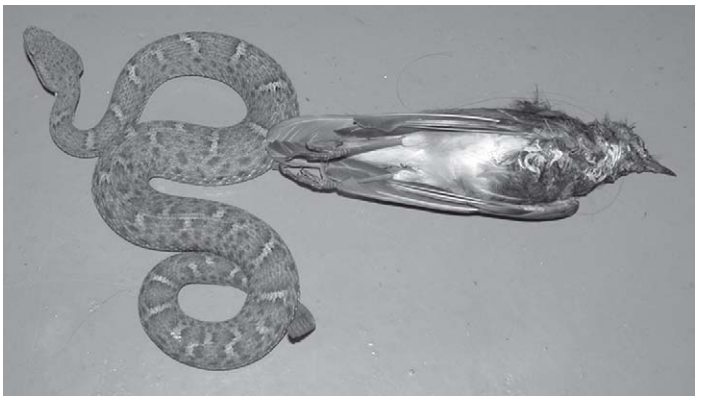

FIG. 1. Female *Crotalus willardi* with a male *Catharus guttatus* she attempted to swallow.

ELAPHE CARINATA CARINATA (Keeled Rat snake). **DIET.** Keeled rat snakes appear to be dietary generalists and have been known to prey on mice, rats, birds, bird eggs, frogs, lizards, snakes and reptile eggs (Schulz 1996. A monograph of the Colubrid snakes of the genus *Elaphe* Fitzinger. Koeltz Scientific Books, Würselen, Czechoslovakia. 439 pp.).

In September 2004 a monitoring program was initiated in a wetland habitat near an industrial park of Taoyuan County, northern Taiwan. We collected YOY *Elaphe carinata carinata* with prey items in their stomachs in permanent drift fence/funnel traps on 18 February, 26 March and 31 March, 2 males (391 and 393 mm SVL, 28 and 33 g) and 1 female (410 mm SVL, 37.7 g), respectively. The fence was set along the bank of a pond, where the dominant vegetation consists of *Bambusa oldhamii*, *Broussonetia papyrifera*, *Lantana camara*, and *Pennisetum purpureum*. Forced regurgitation revealed that the snakes had consumed one *Crocidura attenuata* (Tanaka's Gray Shrew), two newborn *Apodemus agrarius* (Formosan Striped Field Mouse), one *Laevicaulis alte* (garden slug), and one *Takydromus stejnegeri* (Stejneger's Grass Lizard). In Taiwan, a chick, a beetle (Scarabaeidae), a grasshopper (Acridiidae), a damselfly (Euphaeidae) (Lin et al. 1995. Foods of snakes from Taiwan. NOW 3:19-21), *Dinodon rufozonatum* (Lee and Lue 1996. A preliminary study on the food habits of snakes in Taiwan. Biol. Bull. National Taiwan Normal University. 31:119-124), *Ptyas mucosus* (Hsien-Pin Chu, pers. comm.), and *Rattus rattus* (Norval *pers. obs.*) have been recorded as prey of *Elaphe carinata carinata*. To our knowledge this appears to be the first record of this snake species preying on shrews and land slugs.

We thank Ying-Ping Fang and Wei-Shin Jenq for assistance with identifications.

ELAPHE VULPINA (Western Foxsnake). **HABITAT USE**. *Elaphe vulpina* is a state endangered species (Missouri Dept. Conservation 2006. Missouri Species and Communities of Conservation Concern, Jefferson City, Missouri. 58 pp.) that occurs in northern Missouri, including Squaw Creek National Wildlife Refuge (SCNWR). Past research conducted on SCNWR suggests this spe-

cies avoids wetland centers and is associated with wetland prairies, wetland edges and developed lands (Shew 2004. Spatial Ecology and Habitat Use of the Western fox Snake (*Elaphe vulpina vulpina*) on Squaw Creek National Wildlife Refuge. Masters thesis. Southwest Missouri State University, Springfield, Missouri. 51 pp.). Although observations have been made of this species preying upon duck nests on wetland edges (Wheeler 1984. Wildl. Soc. Bull. 12:77–78), they have not been reported to utilize wetland centers containing relatively deep water habitat (> 90cm).

During the period of May through mid-June 2005 and 2006, ca. 50 *E. vulpina* were observed utilizing deep water wetland habitats in a 239-ha marsh located on the southwest portion of SCNWR, Holt County, Missouri, USA. Individuals were typically observed in cattail (*Typha* sp.) patches coiled on Red-wing Blackbird (*Agelaius phoeniceus*) and Yellow-headed Blackbird (*Xanthocephalus xanthocephalus*) nests, ca. 60–90 cm above the surface of the water. Using a geographic information system we calculated that the snakes had to swim a minimum of 130 m to reach the cattail patches where they were located. Utilization of this habitat type has been observed on SCNWR annually since 2001 by refuge staff members.

Although *E. vulpina* were never observed feeding on eggs or nestlings, depredation was suspected as this appears to be one of the major food resources in this habitat type during this time period which coincides with nesting period of several bird species. The three dominant species of arboreal nesting birds located in this habitat include the aforementioned blackbirds and Least Bittern (*Ixobrychus exilis*). Additionally, five other species of platform nesting birds may also be found in this habitat including Piedbilled Grebe (*Podilymbus podiceps*), American Bittern (*Bontaurus lentiginosus*), Ruddy Duck (*Oxyura jamaicensis*), American Coot (*Fulica americana*), and Common Moorhen (*Gallinula chloropus*). The eggs and nestlings of all of these species represent potential prey items. Cattail patches as well as other deep water wetland vegetation may play a more significant role in the spatial ecology of the species than previously suspected. This relationship is likely on a temporal basis that coincides with wetland breeding bird activity. Further research on the habitat use of *E. vulpina* within managed wetlands may prove useful in fully understanding the ecology of this species.

Submitted by **AMANDA D. GRIFFIN**, **FRANCIS E. DURBIAN** and **RONALD L. BELL**, U,S. Fish and Wildlife Service, Squaw Creek National Wildlife Refuge, PO Box 158, Mound City, Missouri, 64470-0158, USA; e-mail (FED): frank_durbian@fws.gov.

FARANCIA ABACURA REINWARDTII (Western Mud Snake). **REPRODUCTION**. Information regarding reproduction of *Farancia abacura reinwardtii* is limited due, in part, to its secretive habits. Specifically, copulation has only been reported once, by Anderson (1965. The Reptiles of Missouri. Univ. Missouri Press, Columbia. 330 pp.). Herein, we report on copulation of *F. a. reinwardtii* from Reelfoot Lake, Lake County, Tennessee, USA.

On 05 June 2005 at 1100 h, we observed (from a boat) a large (142 cm SVL, 162 cm TL) *F. a. reinwardtii* on the northwest bank of Horse Island Ditch at Reelfoot Lake, Tennessee (36º24'57"N, 89º22'30"W, NAD27). Upon approach, we noticed that the snake was copulating with a smaller individual. We captured the pair after 2–3 minutes of observation, and discovered that the larger individual was a dead, bloated female. The pair was transported, *in coitus*, to the University of Tennessee-Martin Reelfoot Lake Research and Teaching Center at Samburg, Tennessee. Copulation continued until 1430 h, when the smaller male separated from the dead female. The male (ca. 95 cm TL) was returned to the point of capture the following day. The female was deposited into the Herpetology Collection at Middle Tennessee State University (MTSU 178S).

We could determine neither the cause nor timing of death of the female, or if copulation was initiated before or after the female died. Although from the bloated appearance of the female, we speculate post-mortem initiation of copulation. In field experiments, several snake species have followed chemical trails left by (and courted with) recently deceased females (Shine et al. 2000. Behaviour 137:727–739). Besides providing an additional observation of post-mortem copulation, our observation on 05 June appears to be the earliest report of copulation for *F. a. reinwardtii*. Copulation in Western Mud Snakes has been observed as early as 13 June in southeastern Missouri (reported by Max Nickerson in Anderson 1965, *op. cit.*). Additionally, this observation supports the conclusions of Robinette and Trauth (1992. Proc. Arkansas Acad. Sci. 46:61–64) that the reproductive cycles of both male and female *F. a. reinwardtii* peak in May and June. Research was supported by a grant to VAC from the Tennessee Wildlife Resources Agency (Contract Num. ED-05-01679-00). Specimen was collected under authorization of the Tennessee Wildlife Resources Agency (permit no. 1798).

LAMPROPELTIS PYROMELANA (Sonoran Mountain Kingsnake). **PIGMENT LOSS.** On 22 September 2003 we captured a normally pigmented adult female *Lampropeltis pyromelana* (622 mm SVL, 74.0 g) in the northern Sierra San Luis (Chihuahua, México; 31°18.1'N, 108°45.9'W, 1878 m elev.). We surgically implanted a radio transmitter, and released her on 27 September 2003. Between 28 September and 2 November 2003 we relocated this individual five times, however we observed her only once, on 2 November, at which time she weighed 71.3 g, and remained normally pigmented. We next relocated this snake on 17 May 2004. Although she had lost considerable weight (mass 59.6 g), and had an open, dry wound along her side exposing a small section of the transmitter antenna, the snake seemed to be in good health otherwise, and exhibited no signs of infection or systemic disease. However, she had lost some pigment. Most orange bands exhibited areas where the orange had been replaced by an uneven alabaster to faded salmon coloration. Pigment loss was most severe dorsally, with pigment loss extending down towards the venter in some bands. Most white bands were unchanged, however small areas along the dorsum of some bands had changed from cream to alabaster. Black bands were unaffected by any pigment loss. Coloration on both the head and tail remained unchanged.

Mid-body bands were more severely impacted than were bands closer to the snake's head and tail. The snake's venter remained normally pigmented along the length of the snake. Pigment loss was not centered at the site of the surgical scar, nor did the snake display any natural wounds or evidence of skin disease. We removed the transmitter from this individual on 18 May 2004 and did not again observe her after her release. Hence, we cannot speculate on the permanence of this color change. We observed 28 other *L. pyromelana* in the Sierra San Luis and contiguous areas of the Sierra Pan Duro during 2002–2004, all of which were typically colored.

We thank Rocky Mountain Research Station, U. S. Forest Service for funding.

LEPTOTYPHLOPS BORRICHIANUS (NCN). **PREDATION**. *Leptotyphlops borrichianus* is known from La Rioja, San Juan, Mendoza, and Rio Negro provinces in Argentina (Cei 1993. Reptiles del centro, centro-oeste y sur de la Argentina. Herpetofauna de zonas áridas y semiáridas. Mon. IV Mus. Reg. Sci. Nat. Torino. 524 pp). Here we report an incidence of predation on *L. borrichianus* in San Juan, Argentina (31°31'44"S, 68°41'44"W). A male (140 mm SVL) *L. borrichianus* was discovered in the stomach of a male *Bufo arenarum* (89 mm SVL) during the course of a dietary study. The *B. arenarum* had been collected from a desert shrubland dominated by *Prosopis* sp., *Bulnesia retama, Solanum eleagnifolium*, *Caparis atamisquea*, *Grabousquia obtusa*, and *Tamarix gallica.*

Submitted by **LORENA B. QUIROGA, EDUARDO A. SANABRIA** and **JUAN C. ACOSTA,** Departamento de Biología e Instituto y Museo de Ciencias Naturales, F.C.E.F. y N., Universidad Nacional de San Juan, Avenida España 400 (N) C.P. 5400, San Juan, Argentina (e-mail: quiroga_lore@yahoo.com.ar).

LIOPHIS MILIARIS (Common Water Snake). **PREY**. In the wild *Liophis miliaris* feeds on a wide array of ectothermic prey, including a variety of amphibians (adults, larvae, and eggs), lizards, amphisbaenids, and fish (Michaud and Dixon 1989. Herpetol. Rev. 20:39–41; Chicarino et al. 1998. XXII Congresso Brasileiro de Zoologia, Recife 271–272). In August 2005 we collected a juvenile female of *L. miliaris* (310 mm SVL, 70 mm tail length, 16.3 mm head length; 10 g) moving along an unpaved road at Caucaia do Alto, São Paulo, Brazil (23°41'S, 47°01'W, 895 m elev.). The snake contained a recently ingested juvenile *Bufo ornatus* (29 mm SVL, 1.3 g). To the best of my knowledge, this species has not been previously documented in the diet of *L. miliaris*. Both specimens are deposited in the Coleção Herpetológica "Alphonse Richard Hoge," São Paulo, Brazil (IBSP 73.469).

I thank Valdir José Germano (IBSP) and Jorge Jim (UNESP, Botucatu) for assistance.

Submitted by **MARCELO RIBEIRO DUARTE**, Laboratório de Herpetologia, Instituto Butantan, CEP 05503-900 São Paulo, SP, Brazil (e-mail: mrduarte@butantan.gov.br).

LYSTROPHIS HISTRICUS (Rayed or Jan's Hog-nosed Snake). **DIET.** No specific prey records have been published for *Lystrophis histricus*, probably because the species is scarce throughout its distribution and poorly represented in zoological collections. Several authors suggest that amphibians appear in the diet (Amaral 1977. Serpentes do Brasil: Iconografia Colorida. Univ. São Paulo, Ed. Melhoramentos, Inst. Nac. Do Livro y Universidade de Sao Paulo. 248 pp.; Schouten 1931. Rev. Soc. Ci. Paraguay 1:5–32) but do not cite specific records.

We discovered prey remains in the guts of two of three specimens held in the Uruguay Museum of Natural History collection (MNHN). A male (MNHN 58; 270 mm SVL) collected in 1914 in Departmento Maldonado contained two reptilian eggs (11 × 5 mm and 10 × 6 mm). A female (MNHN 87; 249 mm SVL) collected on 23 March 1935 in the Departmento Cerro Largo contained one eggshell that measured ca. 25 mm length. Based on the comparison with reptile eggs deposited in the Faculty of Sciences Collection, we believe that the eggs eaten by MNHN 58 are *Cercosaura schreibersii* (supported by number of eggs, size, color, and shape). The shell found in MNHN 87 appears to be than of an amphisbaenid (based on shape and size). These observations indicate that the diet of *L. histricus* includes the eggs of other reptiles.

Submitted by **SANTIAGO CARREIRA** (e-mail: carreira@fcien.edu.uy), Museo Nacional de Historia Natural y Antropología, 25 de Mayo 582, CP 11000, Montevideo,Uruguay; and **IGNACIO LOMBARDO**, Sección Zoología Vertebrados, Facultad de Ciencias, Iguá 4225, CP 11400, Montevideo,Uruguay.

MASTICOPHIS SCHOTTI SCHOTTI (Schott's Whipsnake). **MAXIMUM SIZE RECORD**. *Masticophis schotti schotti* is a large, long-tailed (to 38% TL), boldly striped whipsnake inhabiting arid scrub and grassland throughout south central Texas in the United States westward through eastern Coahuila, northern Nuevo Leon, and extreme northern Tamaulipas, Mexico (Camper 1996. Cat. Amer. Amphib. Rept. 638.1–638.4). The maximum size listed for *M. s. schotti* is 1676 mm total length (Boundy 1995. Bull. Chicago Herpetol. Soc. 30:109–122.; Conant and Collins 1998. A Field Guide to Reptiles and Amphibians: Eastern and Central North America. 3rd ed. Houghton Mifflin Company, Boston, Massachusetts. 616 pp.). However, no supporting information exists for this record (locality and date of collection or disposition of the specimen). Herein, we report a new maximum size record for this species.

On 30 September 2005 at 1750 h an exceptionally large female DOR *Masticophis schotti schotti* was collected on Sage Road ca. 120 m east of the junction with farm road 1898 (27°32.292N, 097°52.589W) Kleberg County, Texas, USA. The specimen measured SVL 1169 mm, TL 1681 mm. This exceeds the maximum length previously recorded for this species. The specimen is deposited in the Laboratory for Environmental Biology, Centennial Museum, University of Texas at El Paso (UTEP 19302).

Submitted by **RANDY L. POWELL** (e-mail: randy.powell@tamuk.edu), **M. ANDRES SOTO**, **MICHAEL L. LEIDNER**, and **WENDY R. AUSTIN**, Department of Biology, Texas A&M University-Kingsville, Texas 78363-8202, USA.

MICRURUS ALTIROSTRIS (Southern Coral Snake). **DIET**. The diet of South American coral snakes includes amphisbaenians, lizards, snakes, caecilians, fishes and invertebrates (Souza et al. 2003. Herpetol. Rev. 34:151). *Micrurus altirostris* is a semifossorial species that feeds primarily on amphisbaenids of the genus *Amphisbaena*, and terrestrial, fossorial and semifossorial snakes and lizards (Carreira et al. 2005. Reptiles de Uruguay. Ed. Dirac – Facultad de Ciencias, Montevideo. 639 pp.).

We examined an adult male *M. altirostris* deposited in the Museu de Ciências Naturais da Fundação Zoobotânica do Rio Grande do Sul (MCN 3866, 755 mm total length) and discovered a specimen of *Sordellina punctata* (357+ mm total length) in its stomach. MCN 3866 was probably collected in the state of Rio Grande do Sul, Brazil, though specific collection data are not associated with the specimen. The prey was swallowed headfirst and its head was completely digested. *Sordellina punctata* is a diurnal, semiaquatic snake that feeds on earthworms (Marques et al. 2001. Serpentes da Mata Atlantica - Guia Ilustrado para a Serra do Mar. Ed. Holos, São Paulo, 184 pp.). This is the first record of *Sordellina punctata* in the diet of *Micrurus altirostris.*

We thank Moema Leitão de Araujo, Nelson R. de Albuquerque, and the Conselho Nacional de Desenvolvimento Científico e Tecnológico for assistance.

Submitted by **LUÍS FELIPE S. AGUIAR** (e-mail: lufecotiara@yahoo.com.br) and **MARCOS DI-BERNARDO***, Laboratório de Herpetologia, Museu de Ciências e Tecnologia y Faculdade de Biociências, Pontifícia Universidade Católica do Rio Grande do Sul, Avenida Ipiranga 6681, 90619-900 Porto Alegre, Rio Grande do Sul, Brazil. * Deceased.

OXYBELIS FULGIDUS (Green Vine Snake). **PREY**. The diet of *Oxybelis fulgidus*, a neotropical, arboreal colubrid, consists of lizards and small birds (Martins and Oliveira 1998. Herpetol. Nat. Hist. 6:78–150). Prior to this report, the largest bird consumed by *O. fulgidus* was a *Thraupis episcopus* (Martins and Oliveira, *op. cit.*) which average 165 mm in length (Hilty and Brown 1984. A Guide to the Birds of Colombia. Princeton University Press, Princeton, New Jersey. 996 pp.).

Here we report predation upon an adult *Monasa nigrifrons* (Black-fronted Nunbird; ca. 280 mm) in March 2002 on the border of a seasonally flooded Amazonian forest at the Mamirauá Sustainable Development Reserve, Amazonas State, in northwest Brazil (03°03'S; 64°50'W). The forest floor was partially flooded by rising waters and the snake was first observed in a tree ca. 3 m above the water at around mid-day. The snake did not constrict the bird, but grasped it near the head and let it hang until it seemed to be dead (Fig. 1), whereupon the bird was ingested head-first. Despite its size the bird was completely ingested in less than 30 min.

We thank the Conselho Nacional de Desenvolvimento Científico e Tecnológico, Setor Mamirauá, M. Menin, and F. Waldez for assistance.

PITUOPHIS CATENIFER (Bullsnake). **MAXIMUM LENGTH**. The Eastern Indigo Snake (*Drymarchon corais couperi*) has been heralded as the longest native snake in the United States, having been documented to reach 2629 mm TL (Boundy 1995. Bull. Chicago Herpetol. Soc. 30:109–122). Although Dixon (1952. Copeia 1952:193) reported a bullsnake measuring "9ft" (2745 mm), he took this measurement from a skin and not a whole animal (J. Dixon, pers. comm.). In June 1999 one of us (AM) collected a *Pituophis catenifer* near Loma Alta (Val Verde County, Texas, USA) that measured 2667 mm TL on 12 October 2001 after being kept and fed in captivity for ca. 2 years (Fig. 1). This specimen represents a new record for the longest native snake in the United States and extends the record length for the genus *Pituophis* by 127 mm (Boundy, *op. cit.*). A voucher image of this snake has been deposited in the Texas Natural History Collection (TNHC 65425).

FIG. 1. Armin Meier (185 cm) with a *Pituophis catenifer* (2667 mm TL) captured in Val Verde County, Texas.

PITUOPHIS MELANOLECUCUS LODINGI (Black Pinesnake). **TREE CLIMBING**. On 11 April 2005 a non-gravid female *Pituophis melanoleucus lodingi* was captured on the Camp Shelby Training Site, Forrest Co., Mississippi, USA and implanted with a temperature sensitive radio-transmitter (Hohohil SI-2T). Upon release, the snake immediately climbed an *Ilex vomitoria*, and attained a height of ca. 4 m; it remained in the shrub until we left (~20 min later). When the snake was relocated on 12 May 2005, it was found 2 m off the ground in a *Magnolia virginiana*, it remained motionless until we left. The next day it was located 4–5 m off the ground in an *Ilex vomitoria* and upon our approach it moved into the branches of a *Quercus incana*. On 16 May 2005 this snake was located 4 m off the ground in an *Ilex vomitoria*, and remained motionless while it was photographed. On 8 June 2005 this snake was found dead on the road. Of the 23 observations made of this animal it was found in trees or shrubs on only the four occasions (17%) described above. To the best of our knowledge this is the first report of arboreality for this subspecies.

Submitted by **MELISSA A. OLSEN** and **JAMES R. LEE**, The Nature Conservancy, Camp Shelby Field Office, CSTS-ENV Building 6678, Camp Shelby, Mississippi 39407, USA (e-mail: molsen@tnc.org).

PITUOPHIS MELANOLEUCUS LODINGI (Black Pine Snake). **BEHAVIOR.** When threatened, *Pituophis melanoleucas lodingi* retreat into a defensive coil and hiss loudly (Cook 1943. Snakes of Mississippi. Survey Bull., Mississippi Game and Fish Comm., Jackson, Mississippi. 73 pp.) or attempt to escape into nearby subterranean refugia, most often stump holes (D. Baxley, pers. obs.). The following account is the first record, to our knowledge, of *P.m. lodingi*, seeking an arboreal retreat when threatened. On 30 July 2005 at 1350 h we radio-tracked an adult female *P.m. lodingi* within a recently burned stand of *Pinus palustris* (longleaf pine) adjacent to a mesic bottom-land area in Wayne County, Mississippi, USA. Presumably in response to our presence, the snake moved towards the bottom-land area while the observer recorded locality and temperature data. At 1401 h the snake was observed, hissing loudly, 1.83 m above the ground, coiled in the crook of a *Quercus nigra* (Water Oak). Of 112 previous radio-telemetry location records for six individuals between 24 April and 30 July 2005, no other occurrences of tree use by *P. m. lodingi* have been recorded.

Submitted by **DANNA BAXLEY** (e-mail: Dannaster@yahoo.com) and **CARL QUALLS**, Department of Biological Sciences, University of Southern Mississippi, Hattiesburg, Mississippi 39406-0001, USA.

REGINA RIGIDA SINICOLA (Gulf Crayfish Snake). **DIET**. *Regina rigida* is a secretive snake that inhabits the lowlands of the southeastern United States (Conant and Collins 1991. Reptiles and Ampbihians Eastern/Central North America. Houghton Mifflin, Boston, Massachusetts. 450 pp.). They feed predominately on both soft and hard-shelled crayfish; however, they are also known to prey on fish and amphibians (Ernst and Ernst 2004. Snakes of the United States and Canada. Smithsonian Institution Press, Washington, DC. 680 pp.). On 12 November 2004 we collected three males and one large female (69 cm SVL) in a single aquatic funnel trap placed in a small backwater slough (30.98ºN, 87.92ºW), in the Mobile-Tensaw Delta Wildlife Management Area (MTD) Baldwin Co., Alabama, USA. All four snakes were transported to the University of South Alabama Vertebrate Natural History Museum (USAVNHM) to acquire tail clippings for DNA. Snakes were then placed into separate cages overnight. Early the next morning we noticed the female snake had defecated in her cage, we found her feces to be primarily composed of crayfish pieces. However, upon closer inspection we discovered mammalian hairs and uni-

dentifiable bone fragments in the feces. Given the amount of fur and the presence of bones in the feces we feel it unlikely the hair was secondarily ingested. The hairs were identified as that of a Golden Mouse (*Ochrotomys nuttalli*), a common resident of the MTD. Slides were deposited at the USAVNHM. This is the first record of *Regina* spp. consuming mammalian prey. It is possible the snake mistook the mouse for its normal prey (crayfish). Alternately, large *Reginia rigida* might occasionally take mammalian prey as part of their diet.

We thank Suzanne Peurach of the USGS Patuxent Wildlife Research Center at the Smithsonian Institution for identifying the hairs of the Golden Mouse.

Submitted by **GABRIEL J. LANGFORD**, Department of Biological Sciences, University of Nebraska-Lincoln, Lincoln, Nebraska 68588, USA (e-mail: glangfo1@bigred.unl.edu); and **JOEL A. BORDEN**, Department of Biology, University of South Alabama, Mobile, Alabama 36688, USA (e-mail: jab315@jaguar1.usouthal.edu).

SIPHLOPHIS PULCHER (NCN). **PREY**. The colubrid *Siphlophis pulcher* feeds primarily on lizards (*Placosoma glabella*, *Hemidactylus mabouia*: Sazima and Argôlo 1994. Herpetol. Rev. 25:126; Prudente et al. 1998. Rev. Bras. Zool. 15:375–383; *Gymnodactylus darwini*, *Tropidurus torquatus*, *Mabuya* sp., *Ophiodes striatus*: Prudente et al., *op. cit.*) and snakes (*Imantodes cenchoa*; Sazima and Argôlo, *op. cit.*). Here we report a new prey record as well as the largest prey/predator mass ratio for this semi-arboreal species. An adult female *S. pulcher* (SVL = 530 mm, tail length = 150 mm, mass = 31 g, IBSP 73308) from Cananéia Island (25º00'S, 47º55'W, 8 m elev.) was collected in remnants of Atlantic Forest in May of 2005 with a freshly eaten *Ophiodes fragilis* (Sauria, Anguidae; SVL = 70 mm, tail = 170 mm, mass = 14 g). The lizard was ingested head first and found in the gut along with its broken tail. Prey/predator mass ratio was ca. 0.451, although the head was partially digested. *Ophiodes fragilis* readily exhibit tail autotomy, we suspect that the tail and lizard were ingested separately. Vouchers of snake and lizard are in the Instituto Butantan, São Paulo, Brazil.

Submitted by **MARCELO RIBEIRO DUARTE**, Laboratório de Herpetologia, Instituto Butantan, CEP 05503-900 São Paulo, SP, Brazil (e-mail: mrduarte@butantan.gov.br); and **MARCO AURÉLIO DE SENA**, Departamento de Genética e Biologia Evolutiva, Instituto de Biociências, Universidade de São Paulo, São Paulo, Brazil (e-mail: mausena@yahoo.com).

STENORRHINA FREMINVILLII (Freminville's Scorpion-Eating Snake). **DIET**. *Stenorrhina freminvillii* is a medium-sized fossorial inhabitant of thorn forest, savannas, and agricultural areas (Lee 1996. The Amphibians and Reptiles from the Yucatan Peninsula. Cornell Univ. Press, Ithaca, New York. 500 pp.). The diet of *S. freminvillii* includes insects, scorpions, and tarantulas (Greene 1997. Snakes. The Evolution of Mystery in Nature. University of California Press, Berkeley and Los Angeles. 351 pp).

On 19 March 2005 at 1120 h, I found a *S. freminvillii* (810 mm SVL, 115 g) feeding on an undescribed scorpion (Diplocentridae, male, 81 mm, 15.3 g) alongside a road in tropical deciduous forest ca. 23 km south of Ejido Caobas (18º14'57"N, 89º03'06"W), Quintana Roo, México. When I first observed the pair, the scorpion was alive and its stinger embedded in the snake's neck. After ca. four minutes the snake began to ingest the scorpion (Fig. 1). I captured the snake and recovered the live scorpion. The scorpion was preserved and the snake was held for behavioral observations. Three days later the snake defecated and its feces contained exoskeletal remains of a tarantula (*Brachypelma vagans*). The scorpion was sent to O. Francke at Universidad Nacional Autónoma de México. The snake will be deposited in the Herpetological Collection of El Colegio de la Frontera Sur, Chetumal, Quintana Roo, México (ECO-CH-H).

FIG. 1. *Stenorrhina freminvillii* consuming an undescribed diplocentrid scorpion.

Submitted by **VÍCTOR H. LUJA,** El Colegio de la Frontera Sur (ECOSUR), Unidad Chetumal. Av. Centenario km 5.5, A. P. 424, C.P. 77000, Chetumal Quintana Roo, México (e-mail: lujastro@yahoo.com). Current address: Centro de Investigaciones Biológicas del Noroeste. Mar Bermejo #195 Colonia Playa Palo de Santa Rita, La Paz, Baja California Sur, 23090, México.

THAMNOPHIS ATRATUS HYDROPHILUS (Oregon Gartersnake). **DIET**. *Thamnophis atratus hydrophilus* use a variety of foraging methods including crawling underwater on the bottom of streams and probing in crevices in search of prey (Lind and Welsh 1994. Anim. Behav. 48:1261–1273). *Thamnophis a. hydrophilus* feed on a variety of prey items including adult ranid frogs and tadpoles (Garwood and Welsh 2005. Herpetol. Rev. 36:165), aquatic salamanders such as the Pacific Giant Salamander (*Dicamptodon tenebrosus*) and fishes such as juvenile salmonids (Welsh and Lind 2000. J. Herpetol. 34:67–74) and sculpins (Brown et al. 1995. Reptiles of Washington and Oregon. Seattle Audubon Society. Seattle, Washington. 176 pp.).

On 28 May 2005 at ca. 1600 h, an adult female *T. a. hydrophilus* (501 mm TL) was captured during routine snake surveys on Spanish Creek (40°11'00"N, 124°15'24"W), located in the King Range National Conservation Area in northern California, USA. We forced the snake to regurgitate a single hard mass of small eggs, each ca. 1.2 mm in diameter. These eggs were later identified as fish eggs

from the genus *Cottus*. Two species of sculpin are known to co-occur in this stream: C*ottus asper* and *C. aleuticus* (W. Duffy, pers. comm.). *Cottus asper* eggs generally are found in burrows or tunnels whereas the eggs of *C. aleuticus* are found under rocks (Kresja 1965. Ph.D. dissertation. University of British Columbia, Vancouver. 109 pp.; Moyle 2002. Inland Fishes of California. University of California Press. Berkeley, California. 502 pp.). Although we did not observe the snake find and consume the eggs, *T. a. hydrophilus* actively forage along stream substrates by probing cracks and crevices, and it seems likely that this individual found the eggs in this manner.

Predation on fish eggs by *T. a. hydrophilus* has not been documented and could represent an important seasonal component of their diet. Our observation suggests that *T. a. hydrophilus* can feed on all life stages of some sculpins.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 38, Number 1 (March 2007, p. 95). Please note that the responsibility for checking literature for previously documented range extensions lies with authors. Do not submit range extension reports unless a thorough literature review has been completed.

CAUDATA

AMBYSTOMA OPACUM (Marbled Salamander). USA: ARKANSAS: Hot Spring Co.: 4.8 km S Lono on St. Hwy. 9 (Sec. 25, T6S, R16W). 4 December 2006. Henry W. Robison. Verified by S. E. Trauth. Arkansas State University Herpetological Museum (ASUMZ 30351). New county record, filling a distributional hiatus in the west Gulf Coast Plain of south-central Arkansas among Clark, Grant, and Saline counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

Submitted by **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@saumag.edu); and **CHRIS T. McALLISTER**, Department of Physical and Life Sciences, Chadron State College, Chadron, Nebraska 69337, USA (e-mail: cmcallister@csc.edu).

AMBYSTOMA OPACUM (Marbled Salamander). USA: TENNESSEE: Sullivan Co.: Off of TVA Road South ca. 100 m NE of intersection with Holston View Dam Road across from Osceola Island parking area (36.5213°N, 82.1081°W). 13 October 1970. Wallace Coffey. Austin Peay State University Museum of Zoology, APSU 18171 (photo of live individual). On this date Coffey and Brent Rowell also had an unvouchered nesting record of one female with 40–50 eggs that was found under a log. An additional specimen was collected 1.5 km SW of the original location along Piney Hill Road (36.5166°N, 82.1222°W). 03 May 1978. Tim Malone. APSU 18170. On the night of 18 March 1998, an individual was observed crossing Holston View Dam Road across from Osceola Island parking area (36.5211°N, 82.1071°W). It was raining and the animal was moving toward a wetland area. Phil Gentry. APSU 03459 (photo of live individual). 21 October 2005. South Holston Weir Dam Wetland 100 m from the 1998 location (36.5237°N, 82.1108°W). Kevin Hamed, Tom Laughlin, and Phil Gentry. Two individuals were observed guarding eggs under leaf litter at the edge of a dry wetland. Verified by A. Floyd Scott, Austin Peay State University Museum of Zoology, APSU 18165 (photo of live individual). An additional 55 nests (41 with females guarding eggs) were found in the same wetland during October and November 2005.

These observations represent the first records from Sullivan County and the only records from upper East Tennessee (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 94 pp. [Hard copy and Internet versions, the latter of which includes a link to information on amphibians in Tennessee having appeared since 1996], http://www.apsu.edu/amatlas, accessed 26 April 2006).

HYDROMANTES PLATYCEPHALUS (Mount Lyell Salamander). USA: CALIFORNIA: Placer Co.: Blackwood Canyon, Fourth of July Chutes (Peak 8514): 39°3'56.8"N, 120°13'35.8"W, 2560 m elev. 20 July and 12 August 2006. T. Will Richardson. Two adults collected 12 August: MVZ 250724–725. Verified by Sean M. Rovito. One probable adult and four juveniles found and photographed on 20 July. Two adults and two juveniles found on 12 August. Found under granite stones on moist decomposed granite gravel near base of cliffs, adjacent to melting snowfields. One adult on 12 August was found under a stone, in matted *Primula suffrutescens* with snowmelt running through it. This population represents the first record for Placer County, the Lake Tahoe basin, and the Truckee River drainage, the northernmost record for the eastern slope of the Sierra Nevada, and the second-northernmost record for the species (Schlesinger and Romsos 2000. Appendix G. Vertebrate Species of the Lake Tahoe Basin, pp. G1–G15 *In* D. D Murphy and C. M. Kopp [eds.], Lake Tahoe Watershed Assessment: Volume II. Appendices. U.S. Forest Service SW-GTR-176; Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd. Ed. Houghton Mifflin, New York). This also bridges a significant gap between the nearest known populations at Smith Lake, El Dorado Co. (23 km S) and Sierra Buttes, Sierra Co. (69 km NW). This report establishes a second salamander species from the Lake Tahoe basin.

Submitted by **T. WILL RICHARDSON** and **C. M. GIENGER,** Department of Biology, MS 314, University of Nevada, Reno 89557, USA.

PSEUDOEURYCEA QUETZALANENSIS (Cuetzalan Salamander). MÉXICO: PUEBLA: Municipality of Zacapoaxtla: Ejido Apulco (19º91'91.7"N, 97º60"67'W), 1450 m elev. 08 May 2004. Carlos Hernández Jiménez. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México (MZFC 19350). First record for municipality and extends the known range ca. 18 km (airline) SE of Xocoyolo, Cuetzalan, Puebla (Parra-Olea et al. 2003. Herpetologica 60:478–484). Municipality of Tlatlauquitepec: Ejido La Unión (19°53'51.3"N, 97°28'38"W), 1585 m elev. 30 August 2005. Israel Solano Zavaleta. MZFC 19301. First record for municipality and extends the known range ca. 11.64 km (airline) from 2 km NE Xocoyolo, Cuetzalan, Puebla (Para-Olea et al., *op. cit.*). Both specimens verified by Edmundo Pérez Ramos. Another individual collected in Tlatlauquitepec, within Ejido Atlalpa (MZFC 19304; 19°51'1.3"N, 97º30'12"W), was found at 1900 m elev., which is the highest recorded elevation for this species (Parra-Olea et al., *op. cit.*). MZFC 19301 and 19350 were found under decaying logs in montane cloud forest; MZFC 19304 was found beneath a rock in pine-oak forest.

Submitted by **ESTRELLA MOCIÑO-DELOYA, URI OMAR GARCÍA-VÁZQUEZ, ISRAEL SOLANO-ZAVALETA,** and **MANUEL ROSADO-LUNA,** Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Ciudad Universitaria, A.P. 70-399, México, D.F. 04510, México (e-mail: allertsemoci@yahoo.com).

SIREN INTERMEDIA NETTINGI (Western Lesser Siren). USA: ARKANSAS: Howard Co.: 3.2 km S Tollette on St. Hwy. 355 (Sec. 20, T11S, R29W). 17 September 2006. Henry W. Robison. Verified by S. E. Trauth. Arkansas State University Herpetological Museum (ASUMZ 30348). New county record filling a distributional hiatus in the Millwood Lake watershed area of southwestern Arkansas among Hempstead, Polk, and Sevier counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

Submitted by **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@saumag.edu); and **CHRIS T. LEPTODACTYLUS PLAUMANNI (Nova Teutonia White-lipped Frog). BRAZIL: Paraná: Municipality of São João do Triunfo (25º34'18"S, 50º05'56"W) 780 m elev. 22 December 2003. A. M. X. Lima. Scientific collection of Instituto de Pesquisas em Cananéia, Cananéia, São Paulo State (MIPEC 024). Verified by R. A. Machado. Individual was collected from a short grass pasture close to Iguaçu River margin while it was calling. Previously known from Argentina in Misiones, and Brazil, in Rio Grande do Sul and Santa Catarina State (Silva et al. 2004. Amphibia-Reptilia 25:186–195). First state record, extends the known range of the species 400 km NE from the municipality of Seara, Santa Catarina State.

Submitted by **ANDRÉ MAGNANI XAVIER DE LIMA**, Programa de Pós-Graduação em Ecologia e Conservação, UFPR, rua Bento Viana, 932, ap 41, CEP 80210-170, Curitiba, Paraná, Brazil; e-mail: "mailto:andremxlima@uol.com.br" andremxlima@uol.com.br.

LEPTODACTYLUS SYPHAX. BRAZIL: GOIÁS: CALDAS NOVAS MUNICIPALITY: 17º43'56"S, 48º40'0"W. 12 August 2002. K. G. Facure. Verified by A. A. Giaretta. Coleção Zoológica da Universidade Federal de Uberlândia (Anura), AAG-UFU 002307. *Leptodactylus syphax* was known from the Brazilian states of Mato Grosso, Minas Gerais, and Paraíba, as well as southern Paraguay and eastern Bolivia (Heyer 1979. Smithson. Contrib. Zool. 301:1–43; Frost 2004. Amphibian Species of the World: An Online Reference. Amer. Mus. Nat. Hist., New York, http://research.amnh.org/herpetology/amphibia/index.php). Adult male, calling in sandy rocks beside water (ca. 35°C). First state record, Caldas Novas is intermediate between previously known localities in Alpinópolis (Minas Gerais State, ca. 500 km SE) and Cuiabá (Mato Grosso State, ca. 800 km NW) (Cardoso and Heyer 1995. Alytes 13[2]: 67–76).

Submitted by **WAGNER R. SILVA** (e-mail: wagnerdrigues@yahoo.com.br) and **KÁTIA G. PHYLLOMEDUSA OREADES (NCN). BRAZIL: MINAS GERAIS: Municipality of Cabeceira Grande, District of Palmital (16º14'S, 47º18'W, 877 m elev.). 18 October 2006. R. R. Carvalho-Jr. and E. G. Pereira. Laboratório de Herpetologia, Museu de Ciências Naturais, Pontifícia Universidade Católica de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil (MCNAM 8294–95). Verified by L. B. Nascimento. *Phyllomedusa oreades* was found only in states of Goiás (Serra da Mesa, Chapada dos Veadeiros, and Serra dos Pirineus) and Distrito Federal (ARIE Capetinga-Taquara and Reserva Ecológica do IBGE, Brasília), Brazil, above 900 m elev. (Brandão 2002. Herpetologica. 36:571–578; Caramaschi 2006. Arq. Mus. Nac. 6[2]:159–179). First state record extends known distribution ca. 295 km airline SE from the type locality, Minaçu/Serra da Mesa, state of Goiás, and ca. 110 km airline from Brasília (Brandão, *op. cit.*).

Submitted by **RONALD REZENDE DE CARVALHO JÚNIOR**, Pontifícia Universidade Católica de Minas Gerais, Museu de Ciências Naturais, Av. Dom José Gaspar 290, Coração Eucarístico, 30536-610, Belo Horizonte, MG, Brazil (e-mail: rcjunior.bh@terra.com.br); and **MARCO ANTÔNIO SCHETTINO CANELAS** (e-mail: cotonhocanelas@yahoo.com).

PLETHODONTOHYLA MIHANIKA (Malagasy Climbing Rain Frog). MADAGASCAR: (1) Masoala Peninsula, Andranobe Field Station, Maroantsetra Fivondronana, Toamasina Faritany (15°39.50'S, 49°57.50'E; 15 m elev.), Museo Regionale di Scienze Naturali di Torino, MRSN A2645. 29 October 1998. J. E. Randrianirina; (2) Masoala Peninsula, Antsarahan'Ambararato, Antalaha Fivondronana, Antsiranana Faritany (15°23.52'S, 50°02.82'E; 500–530 m elev.), MRSN A4594. 9 December 1999. F. Andreone and J. E. Randrianirina; (3) Masoala Peninsula, Mahalevona Maroantsetra Fivondronana, Toamasina Faritany (15°25.12'S, 49°56.77'E, 778 m elev.), MRSN A2705. 09 February 2002. J. E. Randrianirina. Verified by M. Vences. Recently described from eastern Madagascar by Vences et al. (2003. J. Herpetol. 37:629–636). Data on distribution is scanty and known from localities on the east coast of Madagascar, including Ambatovaky, Zahamena, Andasibe, Ankeniheny, Fierenana, Ranomafana, and Sandranantitra. The three new records from Masoala mark the northernmost sites, at ca. 150 km N of Ambatovaky. The specimen from Andranobe was listed as a voucher in a recent mt-DNA analysis on Malagasy cophyline frogs (Andreone et al. 2005. Mol. Phylogen. Evol. 34:315–322). Antsarahan'Ambararato and Mahalevona lie outside boundary of Parc National de Masoala, and fall within relatively undisturbed rainforests. The three specimens measure, respectively, 37.1 mm (MRSN A2645), 34.5 mm (MRSN A2705), and 36.6 mm (MRSN A4594), and are larger than those previously reported (26.4–31.1 mm). They were further assigned to *P. mihanika* because of the longer hind limbs relative to those of *P. notosticta*, the dorsal pattern, and semiarboreal habits. Specimens were captured using a pitfall device associated with a plastic drift-fence, as described by Andreone et al. (2000. Biodiv. Conserv. 9:1587–1622), thus showing the value of this method to detect secretive amphibian species.

Submitted by **FRANCO ANDREONE**, Museo Regionale di Scienze Naturali di Torino, Via G. Giolitti, 36, I-10123 Torino, Italy; e-mail: f.andreone@libero.it.

RANA BLAIRI (Plains Leopard Frog). USA: NEW MEXICO: DONA ANA CO.: Hatch, 0.62 mi S, 0.54 mi E jct. I-25 and NM Hwy 26; T19S, R3W, S9 (NE 1/4); 13S, 3617236N, 0298848E (WGS 84). MSB 71927. 15 September 2004. Shawn Collier. Verified by Charles W. Painter. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. University of New Mexico Press, Albuquerque. 431 pp.).

Submitted by **MICHAEL T. HILL**, Department of Wildlife and Fisheries Sciences, Texas A&M University, 2258 TAMU, College Station, Texas 77843, USA; and **DEBRA M. HILL**, U.S. Fish and Wildlife Service, 500 Gold Avenue, Suite 9019, Albuquerque, New Mexico 87103, USA.

RHINELLA SCITULA. BRAZIL: MATO GROSSO DO SUL: Aquidauana (Piraputanga, Vale das Bruchas, 20°27'23,01"S; 55°29'55,70"W). 08 February 2007. F. P. Maragno. Verified by M. Uetanabaro. Coleção Zoológica do Departamento de Biologia, Universidade Federal de Mato Grosso do Sul, Campo Grande, Brazil (ZUFMS 01254 adult male, SVL 44 mm). Known only from the type locality (Bonito, Mato Grosso do Sul State; Caramaschi and Niemeyer 2003. Boletim do Museu Nacional. Rio de Janeiro. 501:1–16). This new record extends distribution 121 km W from type locality (Caramaschi and Niemeyer, *op. cit*.).

Submitted by **FRANCIÉLE PEREIRA MARAGNO**, Programa de Pós Graduação em Ecologia e Conservação, Universidade Federal de Mato Grosso do Sul, 79070-900, Campo Grande, Mato Grosso do Sul, Brazil (e-mail: fmaragno@gmail.com); and **FRANCO LEANDRO DE SOUZA**, Centro de Ciências Biológicas e da Saúde, Departamento de Biologia, Universidade Federal de Mato Grosso do Sul, 79070-900, Campo Grande, Mato Grosso do Sul, Brazil (e-mail: flsouza@nin.ufms.br).

SYRRHOPHUS CYSTIGNATHOIDES (Rio Grande Chirping Frog). USA: TEXAS: AUSTIN CO.: San Felipe: Stephen F. Austin State Park (29°48'25''N, 096°05'49''W, 155 ft elev.) 3 January 2007, 1430 h, 52°F. Collected by Thomas A. Sinclair, John T. Williams, and Scott A. Wahlberg. Verified by Travis J. LaDuc. Texas Natural History Collections-Texas Memorial Museum-University of Texas (TNHC 65939). New county record (Dixon 2000. Amphibians and Reptiles of Texas. Second Edition. Texas A & M University Press, College Station, Texas, 421 pp.). An adult found under a rotten log next to a *Eumeces fasciatus*, in a torpid state. The animal was released at the site.

Submitted by **THOMAS A. SINCLAIR**, 12903 Cloverwood Drive, Cypress, Texas 77429, USA (e-mail: tsinclair2@houston.rr.com); **JOHN T. SYRROPHUS INTERORBITATLIS (Spectacled Chirping Frog). MÉXICO: SONORA: MUNICIPIO DE YÉCORA: 26.1 km (by Mex. Hwy. 16) E Yécora (28.38234°N, 108.76937°W), 1332 m elev. 7 July 2005. E. Enderson and R. Bezy. Verified by John Lynch. UAZ 56549-PSV. First record for Sonora, extending the range ca. 350 km (airline) N from the vicinity of Guamuchil, Sinaloa (Hardy and McDairmid 1969. Univ. Kansas Publ. Mus. Nat. Hist. 28:39–252). The voucher was one of about 30 others calling in oak woodland.

Submitted by **ERIK F. ENDERSON**, Dryland Institute, PMB 405 2509 North Campbell Avenue, Tucson, Arizona 85719, USA (e-mail: erikenderson@msn.com); and **ROBERT L. BEZY,** Herpetology, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA.

XENOPUS MUELLERI (Müller's Platanna). SOUTH AFRICA: LIMPOPO PROVINCE: 1 km N of Albasini Dam (23°05'47"S, 30°05'22"E, 780 m elev.). 01 December 2004. B. Maritz. Verified by Lemmy Mashinini. Transvaal Museum, Tswane, South Africa (TM 85487–88). Extends the known distribution by at least 50 km from the closest record—the opposite slope of the Soutpansberg Mountains (Minter et al. 2004. Atlas and Red Data Book of the Frogs of South Africa, Lesotho and Swaziland. SI/MAB Series No. 9. Smithsonian Institution, Washington, D.C.). This record also increases the altitudinal distribution by >150 m (previously thought to occur <600 m elev.). Additionally, this is the first record from the Luvuvhu River catchment. *Xenopus laevis* was recorded within 500 m, but not in the same water body. Possible case of micro-allopatry between these two species.

Submitted by **BRYAN MARITZ**, **GAVIN P. R. MASTERSON**, **DARIAN MACKAY**, and **GRAHAM J. ALEXANDER**, School of Animal, Plant and Environmental Sciences, University of the Witwatersrand, Johannesburg, South Africa, Private Bag 3, Wits, 2050, South Africa (e-mail: maritz@gecko.biol.wits.ac.za).

TESTUDINES

ACTINEMYS MARMORATA (Pacific Pond Turtle). MEXICO: BAJA CALIFORNIA NORTE**:** Río San Rafael, 17.12 air km ENE of Punta Colonet near Potrero (31.09353ºN, 116.02786ºW), 157 m elev. 18 May 2005. Thomas Akre, John Blackburn, Antonio Robison, and Robert Lovich. Verified by Jeffrey Lovich. Universidad Autónoma de Baja California UABC 1524. First documented record from the Río San Raphael, although sightings in the upper reaches of the river were reported by Welsh (1988. Proc. California Acad. Sci.46:1–72) and other sightings without precise locality data were mentioned by Roberts (1981. Paper presented during California Riparian Systems Conference, Univ. California Davis, 17–19 September; 1982. Abstr., Proc. Desert Tortoise Council Symposium, pp. 154–161). The record also bridges the distribution gap between known localities in the Río San Telmo (19 km NW) and Río San Juan (35 km SW) reported in Lovich et al. (2005. Herpetol. Rev. 36:200–201). The adult male turtle was observed swimming downstream in a shallow (< 0.5 m), bolder-strewn riffle with gravel substrate.

LACERTILIA

***AMPHISBAENA PLUMBEA*.** ARGENTINA: CHUBUT: TELSEN: Road to Laguna de la Vaca, 5 km SW Provincial Road 4 (42°26'52.6"S 67°18'51.6"W) 667 m elev. 08 February 2007. L. J. Avila, M. Kozykariski, and N. Feltrin. Fundación Miguel Lillo herpetological collection (FML 18118). Verified by R. Montero. This species is endemic to western Argentina and shows a large distribution along Monte phytogeographic formation, from northern Tucumán province to the Atlantic shore of Chubut province. Its geographic distribution is poorly known for Rio Negro and Chubut provinces where only three localities are cited. This is the westernmost record for Chubut and extends the known distribution ca. 200 km W from the nearest records in the coastal areas (Montero 1996. Cuad. Herpetol. 10:25–45).

Submitted by **LUCIANO JAVIER AVILA**, **MONICA KOZYKARISKI**, **NATALIA FELTRIN**, and **MARIANA MORANDO**, CENPAT-CONICET, Boulevard Almirante Brown s/n, U9120ACV, Puerto Madryn (Chubut), Argentina (e-mail: avila@cenpat.edu.ar).

ANOLIS SAGREI (Brown Anole). USA: LOUISIANA: LAFOURCHE PARISH: Thibodaux, Hebert's Nursery, 1500 St. Mary St. 5 October 2006. Michael P. Wiley. Verified by Ernest A. Liner. American Museum of Natural History (AMNH R156219). TERREBONNE PARISH: Houma, Starke's Garden Center, 4836 Hwy. 311. 27 October 2006. Michael P. Wiley. Verified by Ernest A. Liner. American Museum of Natural History (AMNH R156218). New parish records. The owner of Starke's Garden Center has observed *A. sagrei* arriving on shipments of Sable Palm (*Sable major*) from southern Florida. Hebert's Nursery also receives plants from southern Florida. Starke's is located ca. 25 km SSE of Hebert's Nursery. Nearest recorded locations are Orleans Parish (ca. 80 km ENE of Thibodaux; Thomas et al. 1990. Herpetol. Rev. 21:22) and East Baton Rouge Parish (ca. 85 km NNW of Thibodaux; Platt and Fontenot 1994. Herpetol. Rev. 25:33).

CROTAPHYTUS VESTIGIUM (Baja California Collared Lizard). MEXICO: BAJA CALIFORNIA SUR: 9.5 km N of Loreto on peninsular coast facing Isla Coronados (26°05'52.6"N, 111°19'26.9"W), near sea level. 25 September 2004. Armando Tejas. Verified by Jesse L. Grismer. La Sierra University Digital Photo Catalogue (LSUDPC 690–91). Southeastern most record for the Central Gulf Coast phytogeographic region, extending the range 66 km SE from Bahía Concepción (Grismer 2002. Amphibians and Reptiles of Baja California Including Its Pacific Islands and the Islands in the Sea Of Cortez. Univ. California Press, Berkeley. 399 pp.) and a 41 km range extension SE from the closest known locality, 28 km S of San José Comondú on the Sierra de La Giganta (McGuire 1996. Bull. Carnegie Mus. Nat. Hist. 32:1–193), which is located in the arid tropical phytogeographic region.

Submitted by **CRYSTIAN S. VENEGAS-BARRERA**, **GUSTAVO ARNAUD**, Centro de Investigaciones Biológicas del Noroeste, La Paz, B.C.S. 23090, México (e-mail: sadiel@cibnor.mx); and **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515, USA.

CTENOSAURUS SIMILIS (Spiny-Tailed Iguana). USA: FLORIDA: SARASOTA CO.: Englewood, 446 Court Street (26.959367^{0}N, -82.343267^{0}W). 15 January 2007. Missy L. Christie and Cathy A. Olson. Verified by Kenneth Krysko. University of Florida Museum of Natural History (UF 150493, photo voucher). New county record. Although common on Boca Grande, an island ca. 11 miles SE in Charlotte and Lee counties, there are few reports on the mainland. This represents the first report in Sarasota County and is ca. 8 miles N of other reports from Cape Haze (Krysko et al. 2003. Florida Sci. 66[2]:141–146).

HEMIDACTYLUS TURCICUS (Mediterranean House Gecko). USA: ARKANSAS: COLUMBIA CO.: Magnolia city limits (Sec. 31, T16S, R20W). 02 October 2006. Lindsey Fowler. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 30415). Verified by Stanley E. Trauth. New county record in southern Arkansas (Trauth et al. 2004. Amphibians and Reptiles of Arkansas, Univ. of Arkansas Press, Fayetteville). The specimen was taken from an office wall of a local trucking company.

Submitted by **LINDSEY FOWLER** and **HENRY W. ROBISON**, Department of Biological Sciences, Southern Arkansas University, Magnolia, Arkansas 71754-9354, USA (e-mail: hwrobison@saumag.edu).

HEMIDACTYLUS TURCICUS. (Mediterranean House Gecko). USA. LOUISIANA: BEAUREGARD PARISH: Outside walls of South Beauregard High School, 19.31 km N of the Beauregard Parish/Calcasieu Parish line on US Hwy 171. 14 January 2007. Terry Sylvester and Constance Kersten. Verified by Avery Williams. Louisiana State University at Eunice Museum (LSUE 2575–76). First parish record (Meshaka et al. 2006. Herpetol. Conserv. Biol. 19[1]:45–50). The two specimens are sub-adults collected at night. A large population of geckos lives on the brick buildings of the South Beauregard Elementary School/High School complex and has been the subject of population studies since 2005.

Submitted by **TERRY SYLVESTER** and **CONSTANCE KERSTEN**, Department of Biological and Environmental Sciences, McNeese State University, Lake Charles, Louisiana 70609, USA (e-mail: msu-tsylvester@student.mcneese.edu); and **MARK A. PAULISSEN**, Department of Natural Sciences, Northeastern State University, Tahlequah, Oklahoma 74464, USA (e-mail: paulisse@nsuok.edu).

HEMIPHYLLODACTYLUS TYPUS TYPUS (Common Indo-Pacific Tree Gecko). THAILAND: KANCHANABURI PROVINCE: Sai Yok District, Sai Yok Noi. September 2002. M.

Sumontha. Institut Royal des Sciences Naturelles de Belgique, Brussels (IRSNB 17014). Verified by Georges Lenglet (IRSNB). First provincial record. The species is thus presently recorded in Thailand from Kanchanaburi, Nakhon Ratchasima, Narathiwat, Phang-Nga, Phuket, Ranong, Trang, and Trat provinces (Chanard et al. 1999. Amphibians and Reptiles of Peninsular Malaysia and Thailand. An Illustrated Checklist. Bushmaster Publications, Würselen, 240 pp.; Nabhitabhata et al., "2000" 2004. Checklist of Amphibians and Reptiles in Thailand, Office of Environmental Policy and Planning, Bangkok; Pauwels and Bauer 2001. Herpetol. Rev. 32:119).

Submitted by **OLIVIER S. G. PAUWELS**, Department of Recent Vertebrates, Institut Royal des Sciences naturelles de Belgique, Rue Vautier 29, 1000 Brussels, Belgium (e-mail: osgpauwels@yahoo.fr); and **MONTRI SUMONTHA**, Ranong Marine Fisheries Station, 157 M. 1, Saphan-Pla Rd., Paknam, Muang, Ranong 85000, Thailand (e-mail: knotsnake2211@yahoo.com).

HOLASPIS GUENTHERI (Günther's Gliding Lizard). EQUATORIAL GUINEA: Monte Alen National Park. July 2001. T. Stévart. Institut Royal des Sciences Naturelles de Belgique, Brussels (IRSNB 16638). Verified by Georges L. Lenglet (IRSNB). Adult specimen found active by day in secondary forest nr. ECOFAC station and hotel (01°39'N, 10°18'E, ca. 800 m elev.). New record for Park and for Centro Sur Province (Lasso et al. 2002. Graellsia 58[2]:21–34; De la Riva 2004. Quercus 215:56–61). We thank Ignacio J. De la Riva (Museo Nacional de Ciencias Naturales, Madrid) for comments. This is Contribution 89 of the Smithsonian Institution's Gabon Biodiversity Program.

Submitted by **OLIVIER S. G. SCELOPORUS CYANOGENYS (Blue Spiny Lizard). USA: TEXAS: NUECES CO.: South of Bishop, ca. 20 m S of County Road 4, 1 road km E of business Highway 77 (27°34.130N, 097°48.358'W). 08 October 2006. Randy L. Powell. Verified by Travis J. LaDuc. Texas Natural History Collections (TNHC 65743). New county record, extends range east one county (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **RANDY L. POWELL** Department of Biological and Health Sciences, MSC 158, Texas A&M University, Kingsville, Texas 78363, USA; e-mail: randy.powell@tamuk.edu.

SCINCELLA GEMMINGERI (Forest Ground Skink) MÉXICO: QUERÉTARO: MUNICIPALITY OF CADEREYTA DE MONTES: 0.5 km E de Maconi. (20º49'48"N, 99º32'99"W), 1920 m elev. 23 May 1996. Laura Contreras Narváez. Verified by Luis Canseco Márquez. Colección Herpetológica, Facultad de Ciencias, UNAM (MZFC 9781). First record for the municipality and second record for the state, extending the known distribution 44.6 km SW from 1.6 km

W Landa de Matamoros in the Sierra Gorda region, Querétaro (Ketchersid 1974. Herpetofauna of Two Biogeographic Transects in Eastern Mexico. Unpublished dissertation. Texas A&M Univ., College Station), and ca. 40.9 km range extension W from the closest known locality at La Placita, Hidalgo (García-Vázquez 2004. Revisión Taxonómica del Genero *Scincella* [Lacertilia: Scincidae] de México. Unpublished thesis, Univ. Autón. de Puebla, Puebla). The specimen was caught in riparian vegetation.

Submitted by **URI OMAR GARCÍA-VÁZQUEZ** and **ANDRÉS ALBERTO MENDOZA-HERNÁNDEZ,** Museo de Zoología, Facultad de Ciencias, UNAM, A.P. 70-399, México D. F. 04510 (e-mail: urigarcia@gmail.com).

SERPENTES

AHAETULLA FASCIOLATA (Speckled-head Whip Snake). THAILAND: RANONG PROVINCE: Muang District: forest stream near Klong Hat Som Paen (ca. 9°57'N, 98°41'E). 21 February 2004. M. Sumontha. Queen Saovabha Memorial Institute, Bangkok (QSMI 600). Verified by L. Chanhome (QSMI). Found on a tree along a forest stream in syntopy with *Ahaetulla prasina* (voucher at the Institut Royal des Sciences Naturelles de Belgique, Brussels: IRSNB 16997). First provincial record and extension of ca. 175 km N from the previous northernmost locality which is situated at Raman Forest Park, Takua Thung District, Phang-Nga Province (Pauwels et al. 2002. Nat. Hist. J. Chulalongkorn Univ. 2[1]:25–30). We thank Lawan Chanhome (QSMI) and Wudtichai Wungkahart (Ranong Marine Fisheries Station) for working facilities.

Submitted by **OLIVIER S. G. PAUWELS**, Department of Recent Vertebrates, Institut Royal des Sciences Naturelles de Belgique, Rue Vautier 29, 1000 Brussels, Belgium (e-mail: osgpauwels@yahoo.fr); and **MONTRI SUMONTHA**, Ranong Marine Fisheries Station, 157 M. 1, Saphan-Pla Rd., Paknam, Muang, Ranong 85000, Thailand (e-mail: knotsnake2211@yahoo.com).

CLONOPHIS KIRTLANDII *(*Kirtland's Snake). USA: MISSOURI: Clark Co.: Near Wayland (T65N, R6W). 28 April 2006. Christopher Shulse. Verified by J. M. Jones and R. Daniel. Dean E. Metter Memorial Collection, University of Missouri, Columbia (UMC 7936). Rediscovery in state, new county record, only second report west of Mississippi River, and extends the range in Missouri by ca. 51 km. One dead specimen was found on the shore of a constructed pond. Four live specimens were observed near the pond from 28 April – 31 May 2006. This species was first recorded in Missouri in 1964. A single live female was collected on 10 May 1964 in Marion County near Taylor, Missouri (Jones 1967. Herpetologica 23:66–67). No additional specimens were observed until those described herein. Therefore, this species was not included as part of Missouri's herpetofauna by Johnson (2000, The Amphibians and Reptiles of Missouri. Second Ed. Missouri Dept. Conserv., Jefferson City. 400 pp.). Based on these discoveries, *C. kirtlandii* is now considered extant in Missouri and is state ranked as critically imperiled (Missouri Department of Conservation 2007. Missouri Species and Communities of Conservation Concern. Missouri Dept. Conserv., Jefferson City. 50 pp.) This species is known to occur in six other states where it is listed as either state endangered or threatened (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Inst. Press, Washington, DC. 668 pp.), and has an imperiled global rank (Missouri Department of Conservation 2007, *op. cit.*). Additional studies are planned to investigate its distribution and abundance in northeast Missouri (J. Briggler, pers. comm.).

Submitted by **CHRISTOPHER SHULSE**, 212 Tucker Hall, Division of Biological Sciences, University of Missouri, Columbia, Missouri 65211, USA; e-mail: cdsxzc@mizzou.edu.

CROTALUS WILLARDI WILLARDI (Arizona Ridge-nosed Rattlesnake). MÉXICO: SONORA: Municipio de Nogales: Sierra de Pinitos, unnamed canyon on private land S of Los Picos Peaks, ca. 20 km SE (straight line) from the city of Nogales (ca. 31°13'10.15"N, 110°49'30.04"W; UTM: 518000E, 3450000N; horizontal datum ITRF92; ellipsoid GRS80; UTM zone 12), ca. 1524 m elev. 05 May 2006. Robert Villa, Paul Condon, and Trevor Hare. Verified by George L. Bradley. UAZ Sonoran Herpetological Photographic Voucher Initiative, UAZ 56499-PSV (skin with rattle). Westernmost locality for the species in México, extending known range ca. 50 km NW (straight line) from Cananea, Sonora (UAZ 27945). This is also the only record west of the Santa Cruz River. The snake was found in Madrean evergreen woodland.

Submitted by **ROBERT A. VILLA**, 1125 East Missouri Street, Tucson, Arizona 85714, USA (e-mail: herpsandviolin@aol.com); **PAUL T. CONDON**, 8832 East Buckboard Road, Tucson, Arizona 85749, USA; **TREVOR A. HARE** and **SERGIO AVILA-VILLEGAS**, Sky Island Alliance, 738 North 5th Avenue, Suite 201, Tucson, Arizona 85705, USA; and **DAVID G. BARKER**, Vida Preciosa International, Inc., P.O. Box 300, Boerne, Texas 78006, USA.

DENDRELAPHIS KOPSTEINI (Kopstein's Bronzeback Tree Snake). BRUNEI DARUSSALAM: BELAIT DISTRICT: Sungei Rampayoh (04°26'N, 114°24'E). Earlier reported as *Dendrelaphis formosus* (Das 1999. Malayan Nat. J. 53[4]:349–350; Das 2007. A Pocket Guide. Amphibians and Reptiles of Brunei. Natural History Publications [Borneo] Sdn Bhd. Kota Kinabalu. viii + 200 pp.), this species was recently described as new on the basis of specimens formerly identified as *D. formosus* from Thailand, Peninsular Malaysia, Singapore, and Sumatra (Vogel and van Rooijen 2007. Zootaxa 1394:25–45) and diagnosable from congeners in showing the following combination of characters: dark stripe covers only the lower part of temporal region, terminating at rear of neck; nuchal region red in life when inflated; eyes large; two supralabials in contact with orbit of eye. First record for Borneo.

Submitted by **INDRANEIL DAS**, Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, 94300 Kota Samarahan, Sarawak, Malaysia; e-mail: idas@ibec.unimas.my.

LEPTODEIRA SPLENDIDA EPHIPPIATA (Saddled Cat-eyed Snake). MÉXICO: SONORA: Municipio de Yécora, 45.7 km (by Mex. Hwy. 16) E Yécora (28.40430°N, 108.67572°W), 1280 m elev. 06 July 2006. E. Enderson and R. Bezy. UAZ 56548-PSV. Verified by George Bradley. Northernmost record for Sonora, extending the range ca. 232 km (airline) N from the vicinity of Agua Marín, Sonora (Duellman 1958. Bull Amer. Mus. Nat. Hist. 114:1–

152) and 150 km NW of Río Urique, Chihuahua (Tanner 1986. Great Basin Nat. 45:615–676). The snake was DOR in pine-oak woodland.

Submitted by **ERIK F. ENDERSON,** Drylands Institute, PMB 405 2509 North Campbell Avenue, Tucson, Arizona 85719, USA (e-mail: erikenderson@msn.com); and **ROBERT L. BEZY**, Herpetology, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA.

LEPTOPHIS MEXICANUS (Mexican Parrot Snake). HONDURAS: CAYOS COCHINOS ARCHIPELAGO: BAY ISLAND PROVINCE: Cayo Cochino Grande, on east side of island near village of Eastend (15º58'36"N, 86º28'19"W, datum: WGS84), 1 m elev. 22 June 2006. J. A. Frazier. Verified by Robert Henderson. Photographic collection, ASU HP.00057–58). First record for Cayo Cochino Grande (McCranie et al. 2005. Amphibians and Reptiles of the Bay Islands and Cayos Cochinos, Honduras. Bibliomania, Salt Lake City, Utah).

We thank the Honduran Coral Reef Foundation and Operation Wallacea for supporting our research in the Cayos Cochinos.

MASTICOPHIS TAENIATUS (Striped Whipsnake). USA: CALIFORNIA: MODOC CO.: Jess Valley Road (41.23089°N, –120.43909°W, WGS 84). 02 September 2006. Thomas J. Devitt and Susan E. Cameron. Verified by Jimmy A. McGuire. Museum of Vertebrate Zoology (MVZ 253453). New county record. Data were obtained from records held in the following institutions accessed via the HerpNET data portal (http://www.herpnet.org) on 05 March 2006: California Academy of Sciences, San Francisco; Museum of Vertebrate Zoology, University of California, Berkeley. The same results were obtained when all participating providers were included.

Submitted by **THOMAS J. DEVITT**, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720-3160, USA (e-mail: tdevitt@berkeley.edu); and **SUSAN E. CAMERON**, Department of Environmental Science and Policy, One Shields Avenue, University of California, Davis, California 95616, USA.

OPHEODRYS AESTIVUS (Rough Greensnake). USA: ARKANSAS: VAN BUREN CO.: Near Brock Creek Lake: 35.49037°N, 92.80132°W. 15 Oct. 2005. Josh Engelbert, Melissa Patrick, Ashley Patrick, and Mauricio Solis. Verified by Stanley E. Trauth. Voucher specimen in Arkansas State University Museum of Zoology (ASUMZ 29441). Record represents first for county (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville, 421 pp.)

Submitted by **JOSH ENGELBERT, MELISSA PATRICK,** and **MAURICIO SOLIS**, Department of Biological Sciences, Arkansas State University, P.O. Box 599, State University, Arkansas 72467-0599, USA (e-mail: josh.engelbert@smail.astate.edu).

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blindsnake). USA: FLORIDA: CHARLOTTE CO.: Port Charlotte, 2376 Elkcam Blvd (26.99295ºN, -82.103593ºW). August 2003. Joyce Burke. Verified by Kenneth Krysko. University of Florida Museum of Natural History (UF 150413, photo voucher). New county record. This fills in a distributional gap for this non-native species on the west coast of Florida from Pasco County south to Monroe County (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida, Krieger Publ. Co., Malabar, Florida).

Submitted by **GREGG S. KLOWDEN**, University of Florida, Department of Wildlife Ecology and Conservation, P.O. Box 110430, Gainesville, Florida 32611, USA (e-mail: geckoguy@ufl.edu); and **CATHY A. OLSON**, Lee County Department of Parks and Recreation, 3410 Palm Beach Blvd, Fort Myers, Florida 33916, USA (e-mail: colson@leegov.com).

REGINA RIGIDA (Glossy Crayfish Snake). USA: TEXAS: FORT BEND CO.: Cow Creek Rd, 10.7 mi S County Rd 42. 22 May 2006. 423+125 mm; adult female collected DOR. TNHC 66071 (TNHC-FS 4258). Cow Creek Rd, 9.5 mi S TX Rte 762. 21 May 2006. 463+130 mm; adult female collected DOR. TNHC 66072 (TNHC-FS 4263). Verified by Travis J. LaDuc. First two county records, fills in gap within distribution (Dixon 2000. Amphibians and Reptiles of Texas, 2nd edition, Texas A&M University Press, 421 pp.).

Submitted by **DAVID W. HALL**, Department of Genetics, The University of Georgia at Athens, Athens, Georgia 30602, USA.

SEMINATRIX PYGAEA (Black Swampsnake). USA: FLORIDA: NASSAU CO.: US Hwy 301, 2.24 km S of Georgia state line (S of Boulogne near Hwy 301 crossing of Pigeon Creek). 4 September 2005. M. P. Wallace and D. Wallace. Verified by Kenneth L. Krysko. Florida Museum of Natural History photo voucher (UF 144585). New county record (Meshaka and Ashton 2005. *In* Meshaka and Babbitt [eds.], Amphibians and Reptiles Status and Conservation in Florida, pp. 242–282. Krieger Publ. Co., Malabar, Florida).

Submitted by **MARK P. WALLACE**, 784 Kelsall Drive, Richmond Hill, Georgia 31324, USA; and **DIRK J. STEVENSON**, 414 Club Drive, Hinesville, Georgia 31313, USA.

SEMINATRIX PYGAEA (Black Swampsnake). USA: FLORIDA: OKEECHOBEE CO.: CR 724, 0.1 mi E 700A (27.4652°N, -81.0096°W, datum WGS84). 15 March 2006. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 150211). New county record (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part One: The Snakes. Windward Publ., Inc. 176 pp.). Adult found DOR at 2100 h in area of a mixture of dry prairie, marsh, and cattle pasture, and bordered by periodically flooded drainage ditches, which contained Pickerel Weed (*Pontederia cordata*), Wax Myrtle (*Myrica cerifera*), and Cabbage Palm (*Sabal palmetto*). Several live individuals, which were not collected, have been observed on the road or netted out of drainage ditches (Chris Lechowicz, pers. comm.) in the same area.

Submitted by **DANIEL J. PARKER**, 741 Star Fruit Ave, Lake Placid, Florida 33852, USA; e-mail: Mudsnake6@earthlink.net.

SONORA SEMIANNULATA (Groundsnake). USA: NEVADA: PERSHING CO.: Sonoma Range, above Sonoma Creek (40°48'49.0"N, 117°42'29.8"W, 1505 m elev.) under a small rock in sagebrush habitat. 07 May 2006. Bryan Hamilton. Verified by Jack Sites (BYU 8591). Three individuals of this species were observed at this locality in 1993 but no vouchers were collected (Scott, pers. comm.). This record fills a gap in the northeastern distribution of this species with the nearest documented records 64 km E (Battle Mountain, Humboldt Co., Nevada; CAS-SUR 10032), 160 km NW (Denio, Pershing Co., Nevada; Stebbins 2003. Western Reptiles and Amphibians. 3rd Ed.. Houghton Mifflin Co., Boston, Massachusetts, xxx pp.), and 60 km SW (Humboldt House, Pershing Co., Nevada; UNR 493).

Submitted by **BRYAN HAMILTON,** 100 Great Basin National Park, Baker Nevada 89311, USA; and **PAULETTE CONRAD,** Nevada Department of Wildlife, 4747 Vegas Drive, Las Vegas, Nevada 89108, USA (e-mail: pconrad@ndow.org).

TELESCOPUS FALLAX SYRIACUS (Common Cat Snake). LEBANON: HERMEL: Hermel Pyramid (34º22'N, 36º25'E). 28 May 2006. Collected by David Jandzík. Verified by Ján Kautman. Specimen (dead on road) deposited in Slovak National Museum (SNMB St. 634). This is the northernmost country record for the species, extending the range in Lebanon ca. 40 km NE from the closest previous locality in Bcharré (Müller and Wettstein 1933. Sitz. Akad. Wiss., math-naturwiss. Abt. 1 142:135–144; Hraoui-Bloquet et al. 2002. Zool. Middle East 27:35–46).

Submitted by **DAVID JANDZÍK**, Department of Zoology, Faculty of Sciences, Comenius University, Mlynská dolina B-1, SK-84215 Bratislava, Slovakia; e-mail: jandzik@fns.uniba.sk.

THAMNOPHIS ELEGANS ELEGANS (Mountain Gartersnake). USA: CALIFORNIA: AMADOR CO.: El Dorado National Forest, Oyster Lake (38°40'20.0"N, W120°6'59.4"W) 2205 m elev. 5 August 2006. Chris R. Feldman. CAS 233734–35. AMADOR CO.: El Dorado National Forest, unnamed pond 0.5 km NE of Mud Lake via FSR 17E24 (38°36'47.0"N, 120°8'39.0"W) 2402 m elev. 6 August 2006. Chris R. Feldman. CAS 233736–55. Verified by E. D. Brodie Jr. New county record. There is a literature account of *T. e. elegans* from a small, unnamed lake near the southern end of Silver Lake, Amador Co. (Livezey 1953. Herpetologica 9:73) but apparently no vouchers exist to support this record. Otherwise, the nearest known localities are: 3.9 km to the north, Carson Spur, El Dorado Co. (MVZ 67502), 15.7 km to the east, near Blue Lake, Alpine Co. (CAS-SUR 9127), and 21.6 km to the south, Big Meadows, Calaveras Co. (MVZ 65741). Along the western slope of the Sierra Nevada, *T. e. elegans* generally occurs in wet meadows and along pond and lake margins at mid to high elevations (usually above 1200 m). Such habitat is common and *T. e. elegans* is likely contiguous throughout this mountain range.

We thank the California Department of fish and Game for Scientific Collecting permits to CRF (803059-5).

El Salvador is the smallest Central American country, encompassing an area of approximately 21,000 km^2. Despite massive deforestation over the last century due primarily to agriculture practices associated with coffee, corn, cotton, and sugar cane and a national parks system that protects less than 1% of El Salvador's land area (Komar 2002), a panoply of aquatic and terrestrial habitats continue to support a surprising diversity of vertebrates (Serrano 1995). Until recently, but with a few exceptions (e.g., Hidalgo 1983; Mertens 1952), herpetologists had largely ignored El Salvador, which was considered to have the most poorly known herpetofauna in Central America as recently as 2001 (Dueñas et al. 2001). Renewed interest in the last decade has resulted in several new species descriptions, country records, natural history reports, and a book about the Salvadoran herpetofauna

(e.g., Köhler and Kreutz 1999; Greenbaum et al. 2002; Greenbaum 2004; Leenders and Watkins-Colwell 2004; Herrera et al. 2005; and Köhler et al. 2006). Greenbaum and Komar (2005) assessed the threat for each of El Salvador's 130 species of amphibians and reptiles and noted that distribution and taxonomic status of many species remained poorly known.

Herein, we present one new country record and 64 new department records for El Salvador amphibians and reptiles compiled during field work undertaken from 1997 through 2006 that were not reported in Köhler et al. (2006). Abbreviations for museum collections housing voucher specimens include the American Museum of Natural History (AMNH); The University of Kansas Natural History Museum Color Transparency collection (KUCT); The University of Kansas Natural History Museum Digital Archive (KUDA), and Museo de Historia Natural de El Salvador, San Salvador (MUHNES). Most of the following records are based on photographs or digital images of specimens; only photos showing unambiguously diagnostic features are listed as vouchers. All vouchers were verified by Larry David Wilson, except for ones identified separately in the text. Generic name changes identified by Frost et al. (2006a) for several anuran species are recognized. Additional taxonomic changes that differ from Köhler et al. (2006) are discussed in the species records below.

New Country Record

Anura

Ollotis ibarrai. SANTA ANA: Municipio de Metapán, Hacienda Los Planes de Montecristo. 9 October 1976. Victor Hellebuyck. Verified by Joseph R. Mendelson III. AMNH 125854. New El Salvador record based on maps shown by Mendelson et al. (2005), although Köhler et al. (2006) discussed the likely presence of this species within moderate to high elevations (likely between 1800–2400 m) of northwestern El Salvador. Identification of this specimen was determined after reexamination of a toad tentatively identified as *Bufo coccifer* by Köhler et al. (2006). Frost et al. (2006b) recently changed the name of this genus from *Cranopsis* to *Ollotis*.

New Department Records

Gymnophiona

Dermophis mexicanus. USULUTÁN: Municipio de Jiquilisco, Chaguantique protected natural area (13º17'N, 88º33'W), 30 m elev. 18 June 2001. Néstor Herrera. Verified by William E. Duellman. KUCT 11946.

Caudata

Oedipina taylori. SONSONATE: Municipio de Caluco, Plan de Amayo protected natural area (13º41'N, 89º40'W), 260 m elev. 27 December 2002. Néstor Herrera. Verified by William E. Duellman. KUCT 11947.

Anura

Craugastor rhodopis. SANTA ANA: Municipio de Chalchuapa, La Magdalena protected natural area (14º05'24"N, 89º41'3"W), 700 m elev. 12 December 2005. Ricardo Pérez León. Verified by James R. McCranie. KUDA 000104. Crawford and Smith (2005) first recognized *Craugastor* as a distinct genus from *Eleutherodactylus*, and their phylogenetic results do not support the recognition of *Craugastor loki* (Frost et al. 2006a; Lynch 2000).

Leptodactylus fragilis. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 16 September 2005. Néstor Herrera. KUDA 000105.

Leptodactylus melanonotus. LA PAZ: Municipio de Zacatecoluca, Escuintla protected natural area (13º23'33.4"N, 88º54'8.1"W), 50 m elev. 9 September 2001. Néstor Herrera. KUDA 000106.

Lithobates forreri. LA PAZ: Municipio de Zacatecoluca, Escuintla protected natural area (13º23'33.4"N, 88º54'8.1"W), 50 m elev. 9 September 2001. Néstor Herrera. KUDA 000107. LA UNIÓN: Municipio de Conchagua, Laguna Los Negritos (13º16'36"N, 87º55'50"W), 100 m elev. 28 March 2003. Vladlen Henríquez. KUDA 000149.

Ollotis luetkenii. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.9"W), 550 m elev. 21 September 2003. Vladlen Henríquez. KUDA 000100. LA PAZ: Municipio de Zacatecoluca, Escuintla protected natural area (13º23'33.4"N, 88º54'8.1"W), 50 m elev. 9 September 2001. Néstor Herrera. KUDA 000101.

Scinax staufferi. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 16 September 2005. Néstor Herrera. Verified by James R. McCranie. KUDA 000103.

Trachycephalus venulosa. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 16 September 2005. Néstor Herrera. KUDA 000102.

Crocodylia

Caiman crocodilus. SAN MIGUEL: Municipio de El Transito, Laguna El Jocotal, El Desagüe (13º20'N, 88º15'W), 30 m elev. 9 October 1997. Néstor Herrera. Verified by William E. Duellman. KUCT 11953.

Testudines

Kinosternon scorpioides. CHALATENANGO: Municipio de El Paraíso, Santa Bárbara protected natural area (14º04'17"N, 89º05'37"W), 550 m elev. 1 April 2005. Néstor Herrera. KUDA 000108.

Rhinoclemmys pulcherrima. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21"N, 89º57'49.0"W), 550 m elev. 5 May 2006. Pedro Ramón Fuentes. Verified by William E. Duellman. KUDA 000153. CUSCATLÁN: Municipio de Suchitoto, Colima protected natural area (14º02'13"N, 89º07'10.4"W), 300 m elev. 22 September 2004. Vladlen Henríquez. KUDA 000148.

Lacertilia

Aspidoscelis deppii. AHUACHAPÁN: Municipio de San Francisco Menéndez, Laguna El Bijagual (13º41'32"N, 89º34'38.5"W), 30 m elev. 15 May 2004. Vladlen Henríquez. KUDA 000116. SAN VICENTE: Municipio de San Estebán Catarina, Laguna de Chalchuapán (13º42'30.0"N, 88º45'22.4"W), 600 m elev. 25 May 2004. Néstor Herrera. KUDA 000115.

Ctenosaura similis. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 16 September 2005. Néstor Herrera. Verified by Gunther Köhler and James R. McCranie. KUDA 000117.

Gonatodes albogularis. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 400 m elev. 4 October 2003. Vladlen Henríquez. KUDA 000109.

Gymnophthalmus speciosus. USULUTÁN: Municipio de Jiquilisco, Chaguantique protected natural area (13º17'N, 88º33'W), 30 m elev. 28 July 2004. Vladlen Henríquez. KUDA 000114.

Hemidactylus frenatus. AHUACHAPÁN: Municipio de Jujutla, Barra de Santiago protected natural area (13º41'48"N, 89º59'11"W), 5 m elev. 30 December 2005. Néstor Herrera. Verified by Aaron M. Bauer. KUDA 000110. SAN SALVADOR: Municipio de Mejicanos, Residencial Metrópolis Norte, Cantón Zacamil, (13º43'56.52"N, 89º12'44.0"W), ca. 760 m elev. 18 November 2003. Oliver Komar. Verified by William E. Duellman. KUCT 11948. This introduced species was first collected in El Salvador in the department of La Libertad (Greenbaum 2002), and later observed in La Paz by Herrera et al. (2005).

Lepidophyma smithii. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49"W), 550 m elev. 10 January 2004. Vladlen Henríquez. Verified by Gunther Köhler and James R. McCranie. KUDA 000122.

Mabuya unimarginata. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 16 September 2005. Néstor Herrera. KUDA 000120. SAN VICENTE: Municipio de San Esteban Catarina, Laguna de Chalchuapán (13º42'30.0"N, 88º45'22.4"W), 600 m elev. 11 September 2002. Néstor Herrera. KUDA 000121.

Norops sericeus. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 10 January 2004. Vladlen Henríquez. KUDA 000118.

Phyllodactylus tuberculosus. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21"N, 89º57'49.0"W), 550 m elev. 16 September 2005. Vladlen Henríquez. KUDA 000112. CHALATENANGO: Municipio de El Paraíso, Santa Bárbara protected natural area (14º04'17"N, 89º05'37"W), 550 m elev. 1 April 2005. Néstor Herrera. KUDA 000111. LA PAZ: Municipio de Zacatecoluca, Escuintla protected natural area (13º23'33.4"N, 88º54'8.1"W), 50 m elev. 9 September 2001. Néstor Herrera. KUDA 000113.

Sceloporus olloporus. LA PAZ: Municipio de Zacatecoluca, Escuintla protected natural area (13º23'33.4"N, 88°54'8.1"W), 50 m elev. 9 September 2001. Néstor Herrera. KUDA 000119. Although the phylogenetic study of Mendoza-Quijano et al. (1998) did not include samples from Central America, *S. variabilis olloporus* was elevated to species status, which presumably includes *S. variabilis* populations in El Salvador (Köhler et al. 2006).

Serpentes

Agkistrodon bilineatus. LA LIBERTAD: Municipio de La Libertad, Parque Walter Thilo Deininger (13º31'N, 89º16'W), 8 m elev. 24 August 2002. Vladlen Henríquez. KUDA 000144.

Boa constrictor. CHALATENANGO: Municipio de El Paraíso, Santa Bárbara protected natural area (14º04'17"N, 89º05'37"W), 550 m elev. 4 December 2000. Néstor Herrera. KUDA 000147. SANTA ANA: Municipio de Metapán, San Diego-La Barra protected natural area (14º16'2.7"N, 89º28'0.6"W), 472 m elev. 8 May 2005. Vladlen Henríquez. KUDA 000146.

Coniophanes piceivittis. LA LIBERTAD: Municipio de La Libertad, Parque Walter Thilo Deininger (13º31'N, 89º16'W), 200 m elev. 10 September 2002. Néstor Herrera. Verified by William E. Duellman. KUCT 11950.

Conophis concolor. SAN VICENTE: Municipio de San Esteban Catarina, Laguna de Chalchuapán (13º42'30.0"N, 88º45'22.4"W), 600 m. 25 May 2004. Néstor Herrera. KUDA 000123. Pérez-Higareda et al. (2002) elevated *C. lineatus concolor* to species status based on a disjunct distribution of *C. l. lineatus* in central Veracruz, Mexico, and variation in stripe pattern.

Crotalus simus. CUSCATLÁN: Municipio de Suchitoto, Colima protected natural area (14º03'N, 89º08'W), 230 m elev. 12 September 2000. Néstor Herrera. Verified by William E. Duellman. KUCT 11944. First department record with specific locality. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º53'N, 88º57'W), 400 m elev. 9 August 2003. Néstor Herrera. MUHNES 30-1463. CHALATENANGO: Municipio de La Montañona (14º07'N, 88º55'W), 1430 m elev. 1 April 2006. Néstor Herrera. KUDA 000152. SAN MIGUEL: Municipio de San Miguel, Volcán de San Miguel (13º26'N, 88º16'W), 2000 m elev. 3 December 2002. Néstor Herrera. MUHNES 30-1462. Shed skin (with distinctive Mesoamerican rattlesnake diamond pattern) found in a depression under an agave plant in tropical altimontane meadow containing plants in the families Ericaceae, Agavaceae, Onagraceae, and Plantaginaceae. New elevational record in El Salvador (Köhler et al. 2006).

The taxonomic status of *C. simus* in El Salvador is presently controversial. A molecular phylogenetic study by Wüster et al. (2005) indicated that *C. s. simus* (*sensu* Campbell and Lamar 2004) was polyphyletic with respect to a population in Veracruz, Mexico (sister to *C. culminatus*), and a clade from Chiapas, Mexico, El Salvador, and Costa Rica (sister to South American *C. durissus*). The Veracruz population (that renders *C. simus* polyphyletic) is likely to be described as a full species when additional data become available (W. Wüster, pers. comm.). Seemingly unaware of Wüster et al. (2005), Savage et al. (2005) designated a neotype for *Crotalus simus* from Guatemala, presumably based on Campbell and Lamar's (2004) idea of *C. simus*. Until future studies clarify its taxonomy, we recognize El Salvador Neotropical rattlesnakes as *C. simus*, as defined by Campbell and Lamar (2004) and Savage et al. (2005).

Drymarchon melanurus. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 15 September 2005. Néstor Herrera. KUDA 000125. SANTA ANA: Municipio de Santa Ana, Finca Kilimanjaro (13º52'17.1"N, 89º37'17.9"W), 1720 m elev. 31 August 2004. Walter Chacón. KUDA 000124. New elevation record for El Salvador (Köhler et al. 2006). Although Köhler et al. (2006) continued to recognize *D. corais* for Salvadoran populations of *Drymarchon* because molecular data remain lacking, *D. melanurus* has gained common acceptance as a valid species (e.g., Cisneros-Heredia 2006; McCranie et al. 2005).

Imantodes gemmistratus. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N,

89º57'49.0"W), 550 m elev. 22 April 2003. Néstor Herrera. Verified by James R. McCranie. KUDA 000131.

Lampropeltis triangulum. MORAZÁN: Municipio de Osicala, Cantón Llano Alegre (13º48'47.62"N, 88º8'46.17"W), 478 m elev. 21 December 2005. Néstor Herrera. KUDA 000127. SANTA ANA: Municipio de Metapán, San Diego-La Barra protected natural area (14º17'N, 89º29'W), 500 m elev. 18 June 2000. Ricardo Ibarra Portillo. KUDA 000126.

Leptodeira annulata. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 16 October 2005. Vladlen Henríquez. KUDA 000129. LA PAZ: Municipio de Zacatecoluca, Escuintla protected natural area (13º23'33.4"N, 88º54'8.1"W), 50 m elev. 9 September 2001. Néstor Herrera. KUDA 000128. SAN VICENTE: Municipio de San Esteban Catarina, Laguna de Chalchuapán (13º42'30.0"N, 88º45'22.4"W), 600 m elev. 25 May 2004. Néstor Herrera. KUDA 000130.

Leptophis mexicanus. LA PAZ: Municipio de Zacatecoluca, Escuintla protected natural area (13º23'33.4"N, 88º54'8.1"W), 50 m elev. 27 August 2003. Néstor Herrera. KUDA 000132. SANTA ANA: Municipio de Metapán, San Diego-La Barra, (14º17'N, 89º29'W), 500 m elev. 18 June 2000. Roberto Rivera. KUDA 000133.

Loxocemus bicolor. SANTA ANA: Municipio de Metapán, San Diego-La Barra protected natural area (14º17'N, 89º29'W), 500 m elev. 18 July 2002. César Mendoza. KUDA 000143. USULUTÁN: Municipio de Jiquilisco, Laguna San Juan del Gozo (13º14'3.9"N, 88º44'5.0"W), 10 m elev. 2002. Enriqueta Ramírez. Verified by William E. Duellman. KUCT 11949.

Masticophis mentovarius. SONSONATE: Municipio de Caluco, Plan de Amayo, Plan de las Mesas protected natural area (13º40'N, 89º39'W), 260 m elev. 6 August 2002. Néstor Herrera. Verified by William E. Duellman. KUCT 11951.

Micrurus nigrocinctus. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 12 September 2005. Karla Lara. KUDA 000150. MORAZÁN: Municipio de Osicala, Cantón Llano Alegre (13º49'45.91"N, 88º08'50.02"W), 343 m elev. 21 December 2005. Vladlen Henríquez. KUDA 000151.

Ninia sebae. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 7 September 2003. Néstor Herrera. KUDA 000134.

Porthidium ophryomegas. SANTA ANA: Municipio de Metapán, San Diego-La Barra protected natural area (14º16'2.7"N, 89º28'0.6"W), 472 m elev. 8 May 2005. Néstor Herrera. KUDA 000145.

Rhadinaea pilonaorum. SONSONATE: Municipio de Izalco (13º47'18"N, 89º35'37"W), 1000 m elev. 12 August 2005. Vladlen Henríquez. Verified by James R. McCranie. KUDA 000135–36.

Sibon anthracops. SANTA ANA: Municipio de Chalchuapa, La Magdalena protected natural area (14º05'24"N, 89º41'39"W), 700 m elev. 12 December 2005. Ricardo Pérez León. Verified by James R. McCranie. KUDA 000137.

Sibon carri. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 7 September 2003. Vladlen Henríquez. Verified by James R. McCranie. KUDA 000138.

Spilotes pullatus. LA UNIÓN: Municipio de Nueva Esparta, Upire (13º52'36"N, 87º50'28"W), 910 m elev. 4 October 2005. Ricardo Ibarra Portillo. KUDA 000139. USULUTÁN: Municipio de Jiquilisco, Nancuchiname protected natural area (13º22'N, 88º30'W), 30 m elev. 15 March 1997. Néstor Herrera. Verified by William E. Duellman. KUCT 11952.

Stenorrhina freminvillii. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 16 January 2004. Vladlen Henríquez. KUDA 000140.

Thamnophis proximus. CABAÑAS: Municipio de Cinquera, Montaña de Cinquera protected natural area (13º52'21.4"N, 89º57'49.0"W), 550 m elev. 12 September 2004. Néstor Herrera. KUDA 000141.

Trimorphodon biscutatus. CUSCATLÁN: Municipio de Suchitoto, Colima protected natural area (14º02'13.8"N, 89º07'10.4"W), 300 m elev. 22 September 2004. Néstor Herrera. KUDA 000142.

Acknowledgments.—We thank Walter Chacón, Ricardo Ibarra Portillo, Oliver Komar, Karla Lara, César Mendoza, Ricardo Pérez León, Enriqueta Ramírez, Pedro Ramón Fuentes, and Roberto Rivera for permission to include their unpublished records in this paper. We are indebted to Aaron M. Bauer, William E. Duellman, Günther Köhler, James R. McCranie, Joseph R. Mendelson III, and Larry David Wilson for confirming the identification of the records, Linda Trueb and John Simmons for cataloging image records, Christopher Raxworthy for the loan of a specimen from AMNH, David Dickey for AMNH specimen data, and Aaron M. Bauer and Oliver Komar for comments on the manuscript. We extend special thanks to Linda Trueb, Rafe Brown, and John Simmons for initiating a new catalog system for digital media, which was crucial for the publication of this paper.

Tamaulipas lies in the northeastern corner of México; it is bordered to the north by the state of Texas (USA) and by the Gulf of México to the east. Transected by the Tropic of Cancer, the state's relatively small area (ca. 79,389 km^2) has encompassed within its boundaries arid tropical thorn forest, tropical deciduous forest, cloud forest, the eastern limits of the Chihuahuan Desert, beaches and barrier islands at sea level, and pine-oak forest at elevations over 3200 m in the Sierra Madre Oriental. A complete overview of the Tamaulipas herpetofauna has never been published. The pioneering work of Martin (1958), is the most comprehensive, although it was restricted to a limited area of the state and in some aspects was taxonomically flawed (King and Thompson 1968) and is now outdated. Canseco-Márquez et al. (2004) described the herpetofauna known to them from the Sierra Madre Oriental, including southwestern Tamaulipas, in relationship to vegetation types, elevational ranges, and general distributions of included species. However, numerous species that have been documented in the Sierra Madre Oriental of Tamaulipas in various publications, including several recorded in Martin (1958), were overlooked by Canseco-Márquez et al. (2004). Other publications on the amphibians and reptiles of Tamaulipas are few in number, limited in scope, and many included inconsistent and contradictory distributional information.

We have all conducted numerous field surveys within Tamaulipas over the last 15 years, both independently and in collaboration. During that time, we also searched the literature and museum collections for additional distributional data on the herpetofauna occurring within the state. This report addresses information on 20 species, including 19 range extensions involving eight new state records and a statement on one species that we believe should not be counted among the fauna of Tamaulipas, contrary to over 110 years of literature placing it in the state.

Over one hundred natural history museums and universities in Canada, the United States, and México were polled for their amphibian and reptile holdings from Tamaulipas. Sixty-one institutions responded, providing a combined total of approximately 11,500 localities and other data on reptiles and amphibians col-

lected in the state. Museum abbreviations used follow the standard symbolic codes found in Leviton et al. (1985) and Leviton and Gibbs (1988), except the following institutions that were not included in those publications: Instituto Tecnológico Agropecuario de Hidalgo (ITAH), Hidalgo, México; Instituto Tecnológico de Cd. Victoria, (ITCV), Tamaulipas, México; Universidad Autónoma de Ciudad Juárez (UACJ), Chihuahua, México; West Texas A&M University Natural History Museum (WTAMU) Canyon, Texas; and the private collection of Ernest A. Liner (EAL), Houma, Louisiana (The EAL collection was recently donated to the AMNH).

All longitude and latitude coordinates are expressed using the WGS84 (World Geodetic System 1984) datum. Longitude and latitude coordinates and elevations recorded in the original locality data are presented in parentheses ( ). Data in brackets [ ] were obtained either by plotting original localities without corresponding data on topographic maps produced by INEGI (Instituto Nacional de Estadística Geografía Informática), or in some cases, by taking readings with a handheld GPS unit after returning to the original localities. Due to the imprecise nature of some of the original locality data, the supplemented coordinates and elevations presented in brackets should be interpreted as approximate points of collection. Original locality data listed as miles and feet have been converted to metric measurements and presented along side coordinates in brackets. Distances were calculated on INEGI topographical maps and are expressed in air km (not road km) unless otherwise stated. Sierra de Miquihuana, as used herein, includes all areas in the municipality of Miquihuana, Tamaulipas, México, at elevations above 2250 m and lying north of 23°33'N and west of 99°40'W, including El Aserradero, El Capulín, Las Joyas de Miquihuana, Marcela, Valle Hermoso, Sierra El Borrado, Sierra Los Borregos, Sierra La Gloria, Sierra El Pedregoso, and the eastern slopes of Sierra San Antonio Peña Nevada.

Caudata

*Bolitoglossa platydactyla (*Broadfoot Mushroomtongue Salamander). Municipio Gómez Farías: Gómez Farías, Estación Los Cedros [23°02'62"N, 99°09'54"W, 320 m elev.]. 11 January 1994. James R. Dixon. Verified by Kathryn Vaughan. TCWC 71137. Municipio Ocampo: Santa Maria de Guadalupe, 22 km NW of Ocampo (22°54'89"N, 99°29'37"W, 346 m elev.). 11 July 2005. William Farr and José Cortes-Larriva. Verified by Fernando Mendoza-Quijano. UANL 6406. First record for Tamaulipas for both genus and species (Wake and Lynch 1976; Canseco-Márquez et al. 2004) and range extensions of ca. 105 km N for UANL 6406 and *ca*. 120 km N for TCWC 71137, from the nearest locality in southeastern San Luis Potosí (Wake and Lynch 1976). Both localities are situated in tropical deciduous forest.

Chiropterotriton priscus (Primeval Splayfoot Salamander) Municipio Miquihuana: Las Joyas de Miquihuana, 11 km N La Peña (23°39'44"N, 99°42'53"W, 2940 m elev.). 4. July 2004. William Farr, Pablo Lavín Murcio, Gilberto Herrera-Patiño, Oscar M. Hinojosa-Falcón, Ricardo Enrique-Nuñez, Armando Martínez, and Michael R. J. Forstner. Tentatively verified by James R. Dixon (see below). TCWC 90156-161. First record for Tamaulipas, although Rabb (1956) predicted its occurrence there, and a 30 km range extension S from the closest known locality in Nuevo León (Liner 1998a). The identity of this series as *Chiropterotriton priscus* is tentative and may represent examples of an undescribed species discussed by Rabb (1958) from a locality approximately 35 km to the NE in Tamaulipas and addressed in more detail below. All specimens were found on the ground, in and under logs, in dead agaves, and rarely under rocks, in pine-oak-madrone forest with an understory of agaves and scrub heavily littered with fallen logs. Reasons for the tentative identification of these salamanders are discussed below.

The salamanders agree, in most aspects, with the original description of *C. priscus* given in Rabb (1956), including, short legs with three to four costal spaces between adpressed limbs, twelve costal spaces between axilla and groin, eleven distinct costal grooves, and a weak mid-dorsal furrow. However, two key characters given for *C. priscus*, ventral coloration and size seem to be irreconcilable with the series from the Sierra de Miquihuana, and in both features are more consistent with the *Chiropterotriton* sp. discussed in Rabb (1958). Rabb (1956) describes ventral color in *C. priscus* as having "sides progressively lighter than the dorsum as the tan ventral surfaces are approached." Likewise, Liner's (1998a) definition describes a lighter, mostly cream-colored venter. This condition is exactly reversed in the salamanders from Sierra de Miquihuana, with sides progressively darker than the dorsum as the black ventral surfaces are approached, so in this respect they more closely resemble the purported undescribed *Chiropterotriton* represented in Rabb (1958) that had a dark venter. Rabb (1956) does note that ontogenetic variation shows young being considerably darker than the adults, particularly on the venter in *C. priscus*. However, these salamanders were extremely abundant in July and August of 2003 through 2005, so it seems unlikely that of the hundreds of these salamanders observed over three years, all were juveniles.

The average size of the six Sierra de Miquihuana specimens is 31.66 mm snout–vent length (64.33 mm total), with the largest specimen being 37 mm SVL (74 mm total). This is slightly smaller than the 32–42 mm SVL of the *Chiropterotriton* sp. in Rabb (1958), but notably smaller than the 37–50 mm SVL given by Rabb (1956) for *C. priscus*. Rabb (1956) also comments on the robust body of *C. priscus* and notes the resemblance to small individuals of *Pseudoeurycea galeanae*. Subsequent authors (Darda 1994; Liner 1998a; Parra-Olea 2003; Wake and Lynch 1976) all commented on the robust body and *Pseudoeurycea*-like appearance of *C. priscus*. These descriptions would not seem applicable to the small and slender *Chiropterotriton* from the Sierra de Miquihuana. In numerous surveys conducted from 1997 to 2005, many *P. galeanae* were found in and under dead logs and in dead agaves alongside the *Chiropterotriton* in question, but the morphological differences between samples of the two genera from the Sierra de Miquihuana are clear and obvious. Likewise, the general and overall appearance of these salamanders is quite consistent with other species of *Chiropterotriton* (e. g., *C. cracens* and *C. multidentatus*) observed by us in other areas of Tamaulipas.

The coloration of these salamanders can be highly variable. Most, but not all, have a faint and poorly delineated rusty-colored ring or collar around the dorsal part of the neck on a drab and nondescript mottled or peppered ground color of tans, browns and black on the dorsal surface and a darker, mostly black ventral surface. Many individuals have a weak and poorly defined dark line, or sometimes a dark line of weakly defined chevrons, pointing to-

wards the anterior, running down the spine. Another less common "red-backed" variant bears a faint rusty-red dorsal surface on the body and tail outlined by darker pigment that extends down the lateral surface.

Individuals of the undescribed *Chiropterotriton* discussed in Rabb (1958) are currently in the University of Michigan Museum of Zoology (UMMZ 111323–327) cataloged as *Chiropterotriton multidentatus* and have not been examined by us. Rabb (1958) believed these salamanders were clearly related to the two Tamaulipan populations of *C. multidentatus*, but most likely represented another species. Rabb (1958) furthermore included the original description of *Chiropterotriton chondrostega cracens* (= *Chiropterotriton cracens*), and by having previously described *C. priscus*, he obviously believed the undescribed *Chiropterotriton* was distinct from both of those taxa. The UMMZ series were collected by Paul Martin in 1953, from two localities, El Chihue, 17 km by road southeast of Revillagigedo [23°52'N, 99°25'W] Tamaulipas, México, ca. 6200 ft. [1860 m elev.] and from Ojitos Mine, ca. 2 miles [3.21 km] west of El Chihue, 8600 ft. [2580 m], which is ca. 65 miles [104 km] north of the Gómez Farías region (Rabb 1958). One character described by Rabb (1958) in the UMMZ series, the longer length of the legs, is irreconcilable with the salamanders from the Sierra de Miquihuana. Rabb (1958) reported a gap of 1/2 to an overlap of 1/2 of a coastal groove between adpressed limbs in the UMMZ series. Dental characters have not been examined in the present series, although Rabb (1958) questioned their importance for discriminating among taxa in the genus.

More recently, Darda (1994) and Parra-Olea (2003) examined *Chiropterotriton* allozyme variation and DNA from multiple localities throughout México, including samples from all of the currently recognized species in the genus except *C. mosaueri*. Those publications identified at least seven new cryptic species, but left them undescribed, and regrettably did not include samples collected from the Sierra de Miquihuana or from El Chihue, the locality of the UMMZ specimens.

We conclude that these salamanders represent either: a) a southern range extension of *Chiropterotriton priscus* with characters that exceed the current definition of the species, or b) an undescribed species of *Chiropterotriton* geographically located 30 km S of the known distribution of *C. priscus* in adjacent areas of Nuevo León, and 60 km NW of *C. multidentatus* in the Sierra de Guatemala (= El Cielo).

Pseudoeurycea sulcata (Sulcate False Brook Salamander). Municipio Casas: 10 km N of Rancho La Sauceda [23°11'50"N, 99°20'50"W, 1140 m elev.] in the Sierra de Tamaulipas, ca. 39 km N of González. 11 October 2002. Pablo Lavín Murcio and Oscar M. Hinojosa-Falcón. Verified by James R. Dixon (as *P. cephalica*, see below). ITCV 970-971. First record from the Sierra de Tamaulipas and a range extension of 90 km E from the Sierra de Guatemala range of the Sierra Madre Oriental where *Pseudoeurycea sulcata*, *P. bellii*, and *P. scandens* are all documented (Martin 1958; Walker 1955). The Sierra de Tamaulipas is an isolated mountain range located over 50 km E of the Sierra de Guatemala, and separated by 30 km of lowland tropical thorn scrub that is unsuitable habitat for *Pseudoeurycea*. The habitat in the Sierra de Tamaulipas, where these salamanders were collected, is pine-oak forest.

As a side note, a single specimen (KU 129226) cataloged as *Pseudoeurycea scandens*, reportedly collected 9 October 1955, at Agua Linda in the Sierra de Tamaulipas, is in fact a *Pseudoeurycea sulcata*. We consider this specimen as having erroneous locality data and believe it was actually caught 9 October 1965, at Agua Linda, Sierra de Guatemala along with other specimens in the University of Kansas collection obtained by the same collectors on the latter date and location. We are unaware of any locality by the name of Agua Linda in the Sierra de Tamaulipas, whereas Agua Linda in Sierra de Guatemala is a familiar locality and has long been an established destination for biologists (Martin 1955, 1958; Sutton and Pettingill 1942; Walker 1955). Therefore, we consider the record of *P. sulcata* to be the first record for a plethodontid salamander from the Sierra de Tamaulipas. The name *Pseudoeurycea sulcata* has previously been referred most often to *P. cephalica*, which, as pointed out by Frost (2007), is a *nomen nudum*; the next available name is *P. sulcata* (Brocchi 1883), as used herein.

Pseudoeurycea galeanae (Galeana False Brook Salamander). Municipio Miquihuana: Las Joyas de Miquihuana, 11 km N of La Peña. (23°39'30"N, 99°42'65"W), 2936 m elev. 4 July 2004. William Farr, Pablo Lavín Murcio, Gilberto Herrera-Patiño, Oscar M. Hinojosa-Falcón, Ricardo Enrique-Nuñez, Armando Martínez, and Michael R. J. Forstner. Verified by James R. Dixon. UACJ 474. First record for Tamaulipas and a 20–30 km range extension S from the closest known locality in Nuevo León (Liner 1998b). The salamander was caught in pine-oak forest.

Notophthalmus meridionalis (Black-spotted Newt). Municipio Ocampo: Laguna La Loca, 5 km E of El Pensil, 20 km S of Ocampo [22°40'00"N, 99°19'75"W, ca. 300 m elev.]. 27 October 2001. Oscar M. Hinojosa-Falcón and Gilberto Herrera-Patiño. Verified by Jerry D. Johnson. ITCV 683, 741. Westernmost record for this species from throughout its geographical range and a range extension of ca. 37 km W of the vicinity of Ciudad Mante [22°45'00"N, 98°59'00"W, 80 m elev.] (Mecham 1968). Laguna La Loca lies just east of the main body of the Sierra Madre Oriental, and west of the smaller Sierra Tamalave and Sierra Cucharas. Vegetation in the area is tropical deciduous forest.

Anura

Anaxyrus punctatus (Red-spotted Toad). Municipio Jaumave: 5.2–6.2 [road] mi. [8.36–9.97 km] NW Jaumave, Hwy 101 [23°29'N, 99°25'W], 2425–2450 ft. [727.5–735 m] elev. 26 June 1976. James R. Dixon and Carl S. Lieb. Verified by Kathryn Vaughan. TCWC 52642–644. Jaumave [23°24'50"N, 99°23'00"W, 740 m elev.]. 16 May 1946. Hellmuth Wagner. Verified by Gregory Schneider. UMMZ 95237. Hwy 101 at Río Chihue [23°35'30"N, 99°20'10"W, 660 m elev.]. 9 June 1978. Peter Meylan, John Iverson, and Ron Magill. Verified by James R. Dixon from a digital photograph supplied by Kenneth L. Krysko. FLMNH 44080. Municipio San Carlos: 2.6 mi. [4.18 km] WNW San Carlos [24°36'N, 98°58'W, 500 m elev.]. 3 January 1975. Fred. S. Hendricks and party. Verified by James R. Dixon. The distribution of *Anaxyrus punctatus* in Tamaulipas has not been well documented. Frost (2007) and Smith and Taylor (1966) include Tamaulipas in the range of the species, but partial distribution maps in Conant and Collins (1998) and Stebbins (2003) fail to show the species as occurring within the state. The distribution map in Korky (1999) shades a small portion of southwest Tamaulipas, but precise distribution was not supported by any locality dots. Our data reveal *A. punctatus* occurring in 11 of the 43 municipalities in the state, including all five positioned west of the Sierra Madre Oriental. Localities ranging from the Municipio of Burgos in northcentral Tamaulipas, to Soto La Marina (KU 33986) near the Gulf Coast, and Municipio of Antiguo Morelos on the state's southern border (and numerous localities in between), establish the distribution of this species through most of the central and southern two-thirds of the state. Vegetation types occupied by this species in Tamaulipas are predominantly tropical thorn scrub east of the Sierra Madre Oriental, Chihuahua Desert scrub west of the Sierra Madre, and the Jaumave Valley, where elements of both environments overlap. The Antiguo Morelos locality has elements of both thorn scrub and tropical deciduous forest.

Syrrhophus verrucipes (Bigear Chirping Frog). Municipio Palmillas: Near El Llano de Azúas, 15 km S of Palmillas on the road to San Vicente (23°10'04"N, 99°33'24"W), 1506.6 m elev. 11 July 2004. William Farr, Pablo Lavín Murcio, Gilberto Herrera-Patiño, Oscar M. Hinojosa-Falcón, Ricardo Enrique-Nuñez, Armando Martínez, and Michael R. J. Forstner. Verified by James R. Dixon. UACJ 481. New state record and a range extension ca. 200 km NNW of the nearest known locality, 9.6 km W Ahuacatlán, San Luis Potosí (Lynch 1970). This specimen was found under a rock within a canyon in the Sierra Madre Oriental during morning hours in a cleared field that previously contained thorn scrub.

Lacertilia

Basiliscus vittatus (Brown Basilisk). Comments on distribution in northeastern México. Numerous publications including, but not limited to Köhler (2003), Lee (1996), Peters and Donoso-Barros (1970), Savage (2002), and Smith and Taylor (1966), all affirmed that southern Tamaulipas comprises the northernmost geographic range of *Basiliscus vittatus* on the Atlantic slopes of México. Lang (1989) and Maturana (1962) also include Tamaulipas in the range of the species, although maps provided in those publications clearly identify central Veracruz or eastern Hidalgo as the northernmost occurrences based on actual localities. No specimens of *Basiliscus vittatus* from Tamaulipas are cataloged among 11,500 vouchers from the 61 institutions that we queried. Only a very small percentage of the holdings from these collections have been personally examined by us, but misidentification is highly unlikely because *B. vittatus* is easily recognized and not to be confused with other lizards native to Tamaulipas. Additionally, over 20 natural history museums and universities in Europe were surveyed specifically for records of *B. vittatus* from Tamaulipas. Of those, 14 responded and no specimens from Tamaulipas were located. Literature searches have not yielded any locality records specific to Tamaulipas, nor did numerous field surveys conducted over many years.

The origin of the prevailing idea that *B. vittatus* occurs in Tamaulipas might date to Velasco (1892), although Smith and Smith (1976) commented on the probable inaccuracy of his list. An examination of literature published before Velasco revealed no prior references to *B. vittatus* in Tamaulipas (e.g., Boulenger 1885, 1887; Cope 1863, 1887; Duges 1896; Dumeril and Dumeril 1851; Dumeril et al. 1870–1909; Fitzinger 1826, 1843; Griffth and Pidgeon 1831; Günther 1885–1902; Hallowell 1861). Therefore, we judge that *B. vittatus* should not be considered among the herpetofauna of Tamaulipas. Available locality records indicate that central Veracruz is the northern limit of the species in eastern México, as illustrated in the maps of Lang (1989) and Maturana (1962).

Iguana iguana (Green Iguana). Municipio Altamira: 17 km N of Playa Miramar on the road to Puerto Altamira (22°27'00"N, 97°53'00"W), 10 m elev. 16 July 2004. Pablo A. Lavín-Murcio. Verified by James R. Dixon. ITCV 980. First record for Tamaulipas and a range extension of ca. 50 km N of the nearest previously known locality in Veracruz, on the shore of Laguna de Tamiahua, 17 miles [27.5 km] S of Tampico (Smith and Burger 1950; de Queiroz 1995). The specimen was found DOR in a transition zone between a beach and remnants of mangrove forest.

Crotaphytus collaris (Collared Lizard). Municipio Jaumave: near San Vicente, 5 km E of Jaumave (23°25'08"N, 99°19'67"W), 658.5 m elev. 9 September 2005. William L. Farr. Verified by James R. Dixon. UANL 6431. New municipality record and a range extension of ca. 90 km NE from the closest known locality in extreme southwestern Tamaulipas (Axtell and Webb 1995). The habitat in the Jaumave Valley is a combination of elements of Chihuahuan Desert scrub and the tropical thorn scrub of the Tamaulipan plain.

Phrynosoma modestum (Roundtail Horned Lizard). Municipio Villagran: Carretera de Lucio Blanco-San Carlos en San Salvador a 2 km (Terraceria) [Highway from Lucio Blanco to San Carlos, in San Salvador (ca. 24°40'N, 99°20'W), ca. 350 m elev.]. 6 December 1996. David Lazcano. Verified by James R. Dixon. UANL 4311. First municipality record and a range extension of ca. 150 km NE from the only other record of this species in the extreme southwestern corner of the state, as depicted by Whiting and Dixon (1996). This is also the first record for this species east of the Sierra Madre Oriental, although isolated accounts from Jim Hogg, Webb, and Zapata counties, Texas (Dixon 2000; Whiting and Dixon 1996) suggests that this species might be more widely distributed on the Gulf lowlands of northeastern México than currently confirmed. The habitat in this area is arid tropical thorn scrub.

Anelytropsis papillosus (Mexican Blind Lizard). Municipio Tula: San Pablo, 17 km SW of Tula (22°54'35"N, 99°50'51"W), 1103 m elev. 15 August 2004. William L. Farr and Tim Burkhardt. UANL 6740. El Malpais, km 16 carretera Tula SW Ejido Magdaleno Cedillo [22°49'N, 99°53'W, 1050 m elev]. 18 August 2002. Humberto Velez. ITCV 803. Municipio Gomez Farías: 20.5 km by road WNW of Los Estación Cedros in Gómez Farias [22°03'N, 99°14'W, 1360 m elev]. 23 May 1995. J. T. Anderson. TCWC 72818. All verified by James R. Dixon. These localities fill a gap between numerous records in southeastern San Luis Potosí (Campbell 1974) and from 2 miles [3.21 km] SW of Cd. Victoria, Tamaulipas (Axtell 1958). Greer (1985) commented on the wide variety of habitats occupied by this species, but did not list the two plant formations acknowledged herein. The Tula localities are in Chihuahuan Desert scrub within a valley on the western slope of the Sierra Madre Oriental, whereas the record northwest of Gómez Farías is from humid cloud forest on the eastern slopes of that mountain range.

Plestiodon lynxe (Oak Forest Skink). Municipio Antiguo Morelos: 4.0 mi. [6.43 km] N (via Mex. Hwy 85), 0.2 mi. [0.32 km] W of Tamaulipas-San Luis Potosí border [22°27'83"N, 99°05'05"W, 266 m elev.]. 29 May 1980. Laurence M. Hardy. Verified by Amanda Crnkovic and James R. Dixon. LSUS 4513. First record for the state and a range extension of ca. 100 km N of the nearest localities in southern San Luis Potosí (Parker 1960; Webb 1968). The habitat was originally tropical deciduous forest and tropical thorn forest with patches of palm forest, but has since been altered for grazing and agriculture.

Plestiodon obsoletus (Great Plains Skink). Municipio Victoria: Rt. 101, 5 mi. [8.04 km] N Ciudad Victoria [23°50'N, 99°04'W, 200 m elev]. 28 April 1974. John Iverson and party. Verified by James R. Dixon from digital photographs provided by Kenneth L. Krysko. FLMNH 41951. Municipio Tula: El Malpais, km 16 carretera Tula SW Ejido Magdaleno Cedillo [22°49'N, 99°53'W]. 18 August 2002. Humberto Velez. Verified by James R. Dixon. ITCV 794. According to Hall (1976), the nearest recorded localities are from northern Tamaulipas in the vicinity of Matamoros, which is a range extension of ca. 280 km SW for FLMNH 41951 and a range extension of ca. 410 km SW for ITCV 794. FLMNH 41951 is from tropical thornscrub east of the Sierra Madre Oriental and ITCV 794 was from Chihuahuan Desert scrub, west of the Sierra Madre Oriental.

Anguis incomptus (Plainneck Glass Lizard). Municipio Aldama: 11.7 km. NE Aldama. 1983 [day and month not recorded]. Michael Bishop. Verified by Oscar Flores-Villela, Luis Canseco-Márquez, and Carl Franklin. UTA 14069. 19.2 mi. [30.7 km] E Aldama (Carretera 100, Aldama-Barra del Tordo) [ca. 22°57'35"N, 97°49'15"W, 50 m elev.]. 18 July 2006. Chris Rodriquez, Ian Recchio, David Lazcano, and Alan Kardon. Verified by Fernando Mendoza-Quijano. UANL 6824. New state records and range extensions of ca. 150 km NE of the type locality, 7 mi S of Valles, San Luis Potosí (Holman 1971) in tropical deciduous forest. These appear to be only the second and third published records for this species. UANL 6824 was found DOR in tropical thorn scrub, although riparian areas in the region support some tropical deciduous forest. We suspect that UTA 14069 was caught on the same road, so we have reservations about the preciseness of its locality data; specifically the probable direction east as opposed to northeast as originally recorded. Unfortunately the collector is now deceased, thus clarification was not possible. This potential discrepancy will be discussed in more detail below with the intent of identifying specific habitat associations for this extremely rare lizard.

The locality 11.7 km NE of Aldama [ca. 22°59'N, 97°59'W, 430 m elev.] as recorded, is near the center of a small isolated volcanic mountain range covered by oak forest with a maximum elevation of 660 m. This range has no towns or villages, is only accessible by one unpaved road that is not shown on road maps, is unmarked on the highway, and dead ends on private ranch land. To access

this road one must drive north on highway 180 from Aldama approximately 11 km and then return southeast to reach a point 11.7 km NE of Aldama. Although not impossible, it seems extremely unlikely that the specimen came from this out-of-the-way locality.

A more feasible point of origin is 11.7 km E of Aldama [22°57'N, 97°58'W, 140 m elev.] on a paved road leading to the coastal fishing village of Barra del Tordo. The habitat there is arid tropical thornscrub. An examination of this specimen indicated it was DOR. Based on surveys of the area and examining INEGI topographical maps, there is only one road going east from Aldama (no roads going northeast), which is the highway to Barra del Tordo. This highway is on all road maps of Tamaulipas and is one of only four paved roads in the state between Matamoros and Tampico that access the Gulf of México. Barra del Tordo is located northeast of Aldama and without careful analysis it would be reasonable for someone to assume that if they were driving from Aldama to Barra del Tordo that they were going northeast. However, because there are mountains between the two towns, the highway goes east from Aldama and then just a few kilometers before reaching the coast it turns north and parallels the coast to Barra del Tordo.

Serpentes

Boa constrictor (Boa Constrictor). Municipio Jaumave: La Florida, 12 km W of Jaumave (23°23'25"N, 99°30'25"W), 1040 m elev. 11 July 2004. Pablo A. Lavín Murcio. Verified by James R. Dixon. ITCV 974 (head only). Municipio Soto La Marina: Carretera Soto La Marina-La Pesca, en km 16 Rumbo a La Pesca (23°47'48"N, 98°03'01W). 19 July 1997. David Lazcano. Verified by James R. Dixon. UANL 4889. First municipality records and a range extension of ca. 130 km NE for UANL 4889, the northernmost record known to us from the state and northeastern México, and a range extension of ca. 45 km NW for ITCV 974, the westernmost record within the state (Martin 1958). While commenting on specimens from the municipality of Gómez Farías, Martin (1958) stated that the species is restricted to tropical deciduous forest in the south. The Soto La Marina locality is tropical thornscrub of the Tamaulipan plain. La Florida is in the Jaumave Valley where the Tamaulipan plain thornscrub blends with elements of the Chihuahuan Desert.

Hypsiglena torquata (Night Snake). Municipio Bustamante: 7 km S of the town of Bustamante, on the paved road going to highway 101 (23°22'57"N, 99°44'63"W), 1476 m elev. 8 July 2004. William Farr, Oscar M. Hinojosa-Falcón, and Ricardo-Nuñez. Verified from photographs by James R. Dixon. UTA slide collection 31347–349 (three slides of one specimen). Municipio Tula: San Pablo, 17 km SW of Tula (22°54'35"N, 99°50'51"W), 1103 m elev. 15 August 2004. William L. Farr and Tim Burkhardt. Verified from photograph by James R. Dixon. UTA slide collection 31350. New municipality records that fill a large gap in known distribution of this species within the Sierra Madre Oriental of southwestern Tamaulipas (Dixon and Dean 1986; maps in Conant and Collins 1998 and Stebbins 2003). A range extension of ca. 60 km W for UTA 31347–349 from the nearest locality, 3 mi [4.8 km] S of Cd Victoria, Tamaulipas (Dixon and Dean 1986), and a range extension of ca. 50 km E for UTA 31350 from nearest locality in San Luis Potosí (Dixon and Dean 1986). The specimens recorded herein represent only two of many individuals observed within the Sierra Madre Oriental of southwestern Tamaulipas, and all were associated with arid canyons and valleys at elevations below 1476 m.

Masticophis mentovarius (Neotropical Whipsnake). Municipio Aldama: Los Colorados Rancho, 26 km NE, 7 km S Aldama [22°54'50"N, 97°51'00"W, 30 m elev.]. 12 January 1992. James R. Dixon. Verified by Kathryn Vaughan. TCWC 70389. First verified record for the state and a range extension of ca.140 km NE of the nearest known locality, 3 mi [4.8 km] E Taruin [= Tamuin?] (Johnson 1977, 1982; EAL 3429) in southeastern San Luis Potosí. An unconfirmed record mentioned in Blair et al. (1997; WTAMU 312, now apparently lost), from 4 mi. [6.4 km] E Mante, Hwy. 80 [22°43'00"N, 98°53'75"W, 40 m elev.], is located ca. 110 km W of the Aldama record, and is not unexpected. The habitat around the Aldama locality is tropical thornscrub.

Senticolis triaspis (Green Rat Snake). Municipio Soto La Marina: 24 km SW of Soto La Marina on Mexican Highway 70 (23°37'04"N, 98°22'46"W), 397 m elev. 23 October 2004. William L. Farr. Verified by Fernando Mendoza-Quijano. UANL 6741. First municipality record and a range extension of ca. 85 km E of the nearest localities in the vicinity of Cd. Victoria (Schulz 1996). The habitat is a transition zone between arid tropical thorn forest and the more humid montane oak forest located at higher elevations in the Sierra de Tamaulipas to the south. It is curious why Price's (1991) distribution map has the southeastern quarter of Tamaulipas shaded even though there are no locality dots to support his contention. We are unaware of any previous records of this species, published or unpublished, from that region of the state.

Thamnophis exsul (Montane Garter Snake). Municipio Miquihuana: Las Joyas de Miquihuana, 11 km N of La Peña (23°39'44"N, 99°42'53W), 2916 m elev. 8 July 2004. James R. Dixon, Michael R. J. Forstner, and William L. Farr. Verified by Jerry D. Johnson. UACJ 585–86. Las Joyas de Miquihuana,11 km N of La Peña (23°39'50"N, 99°42'37"W), 2884 m elev. 16 August 2004. William L. Farr and Tim Burkhardt. Verified by Fernando Mendoza-Quijano. UANL 6742. First state records and a range extension of ca. 20 km S from 19.6 km NE San Antonio de Peña Nevada, Nuevo León (Liner 1992; Rossman et al. 1989).

Thamnophis exsul was described by Rossman (1969) from a single specimen found 6 July 1961, 17.5 km E, 5.6 km S San Antonio de las Alazanas, Coahuila. Rossman et al. (1989) considered *T. exsul* the rarest of all garter snakes because only 10 individuals were known to them when they redescribed the species. High rates of encounter in our surveys have lead us to the conclusion that this species can be locally abundant, so its reported rarity is probably an artifact of under representation in museum collections, restricted distribution, and remote habitat. As an example, on 8 July and 16 August 2004, eight individuals were observed during about six hours of searching.

A vertical distribution of 2650–2860 m elevation was reported for the species in Rossman et al. (1996). The specimens reported herein were found at slightly higher elevations, between 2884 and 2916 m. Additionally, numerous observations of this species were taken at even higher elevations. A GPS reading of 3007.8 m was recorded for three specimens observed 3 km N of Las Joyas de Miquihuana on 16 August 2004, and others were observed at 3237 m in another study site on Sierra San Antonio Peña Nevada, Zaragoza, Nuevo León, on 29 June 2001 (Lazcano 2005).

Rossman et al. (1996), and our experiences, indicate that this species is not restricted to semiaquatic habitats near water sources, as is typical of most species of *Thamnophis.* All individuals observed in our surveys were fast moving and associated with dead agaves and talus slopes in semiarid terrestrial habitats, even though some small streams, seeps, seasonal pools, and cattle tanks were found in the study areas. Another interesting note is that the distribution of *T. exsul* is largely sympatric with *Crotalus pricei miquihuanus*. There is an ontogenetic change in *T. exsul*, resulting in an adult body form that bears striking resemblance to that small rattlesnake, suggesting a possible Batesian mimetic system involving the two species.

Acknowledgments.—This work was performed under SEMARNAT (Secretaría del Medio Ambiente y Recursos Naturales), Subsecretaría de Gestión para la Protección Ambiental / Dirección General De Vida Silvestre permit numbers 01624 and FAUT 0045 and Project: Distribución y Abundancia de los Anfibios y Reptiles en el Estado de Tamaulipas, México, Oficio No. Doo 7.50.- 7150/97, 21 de Aug. 1997 and Oficio No. SGPA/DGVS/01624 de Feb. 2005. Houston Zoo Inc. provided funds and time for research and fieldwork, and we thank Stan Mays, William Konstant, Alberto Mendoza, Peter Riger, Kelly Russo, Paul Freed, the Conservation Committee, and everyone who has contributed to and participated in the conservation efforts at that organization. We also want to give very special recognition and thanks to James R. Dixon and Kathryn Vaughan at the Texas Cooperative Wildlife Collection (TCWC), Texas A&M University, for their ongoing encouragement, advice, allowing us the use of and to report on holdings in the TCWC's collection and library, securing loan specimens for us to examine, verifying records, and reviewing this manuscript and making valuable suggestion for its improvement. We also thank Michael R. J. Forstner and Alan Kardon for their advice and encouragement. For arranging and allowing us full access to Rice University's Fondren Library, we thank the Houston Zoo and Rice University Consortium in Conservation Biology, Lisa Marie Meffert, Jordan Konisky, and Randolph Tibbits.

We thank the following curators, curatorial assistants, collection managers, and institutions for making loans available, for examining and verifying specimens at our request, providing us with photographs of specimens to examine, and generously allowing us to report on specimens from their respective collections: Kenneth L. Krysko (FLMNH); Laurence M. Hardy and Amanda Crnkovic (LSUS); John Simmons and Omar Torres-Carvajal (KU); Gregory Schneider (UMMZ); Kevin de Queiroz (USNM); Carl Franklin and Jonathan Campbell (UTA); Oscar Flores-Villela and Luis Canseco-Márquez (UNAM); Carl S. Lieb and Jerry D. Johnson (UTEP); Fernando Mendoza-Quijano (ITAH). For responding to our enquires on *Basiliscus vittatus* we thank Mogens Andersen (ZMUC); Mulhauser Blaise (MHNN) Roger Bour (MNHN); José Enrique Gonzalez-Fernandez (MNCN); Kurt Grossenbacher (NMBE); Jakob Hallermann, (ZMH); Günther Köhler (SMF); Georges Lenglet (IRSNB); Colin McCarthy (BMNH); Jirí Moravec (MNHP); Franz Tiedemann (NMW); Wioletta Tomaszewska (MVZ); Raffael Winkler (NMBA); the catalogue of the collection at LIVCM was queried online.

For accompanying us in the field and sharing their knowledge, time, and assistance during the past few years, we thank Omar Martínez-Alvirde, George Brandy, Tim Burkhardt, Jerry Caraviotis, James R. Dixon, Adam Ferguson, Michael R. J. Forstner, Oscar M. Hinojosa-Falcón, Tiffany Kosch, José Cortes-Lariva**,** Armando Martínez, Ricardo Enrique-Nuñez, Gilberto Herrera-Patiño, and David Rodríguez.

Here we report new county records of amphibians from middle Tennessee. Several counties within middle Tennessee have few if any amphibian distribution records in contrast to the more thoroughly documented regions around Reelfoot Lake in northwest Tennessee, the Land Between the Lakes area in north-central Tennessee, and the Great Smoky Mountains in east Tennessee (Redmond and Scott 1996). Localities were determined by either use of a Garmin® global positioning system (GPS) or use of U.S. Geological Survey topographic maps. Voucher specimens were verified by Brian T. Miller and were deposited into the Middle Tennessee State University Herpetology Collection (MTSU) in Murfreesboro, Tennessee. Specimens were collected under authorization of the Tennessee Wildlife Resources Agency (permit no. 1450) and the Tennessee Department of Environment and Conservation (permit no. 2004-018).

Caudata

Ambystoma opacum (Marbled Salamander). RUTHERFORD CO: Larva in spring-fed pond ca. 2.4 km SE of Shiloh (35º51'12.6"N, 86º18'26.8"W). 20 February 2004. M. Niemiller and G. Wyckoff. MTSU 340C.

Desmognathus fuscus (Northern Dusky Salamander). WARREN CO: Adult in Hurricane Hollow Creek on Harrison Ferry Mountain (35º35'38.7"N, 85º38'19.4"W). 11 October 2003. M. Niemiller, B. Glorioso, and G. Wyckoff. MTSU 319C.

Eurycea cirrigera (Southern Two-lined Salamander). WARREN CO: Adult in Hurricane Hollow Creek on Harrison Ferry Mountain (35º35'24.6"N, 85º38'16.8"W). 11 October 2003. M. Niemiller, B. Glorioso, and G. Wyckoff. MTSU 316C.

Notophthalmus viridescens viridescens (Red-spotted Newt). WARREN CO: Eft adjacent to Hurricane Hollow Creek on Harrison Ferry Mountain (35º35'26.9"N, 85º38'14.7"W). 11 October 2003. M. Niemiller, B. Glorioso, and G. Wyckoff. MTSU 315C.

Pseudotriton ruber ruber (Northern Red Salamander). MOORE CO: Adult in creek in Bobo Hollow ca. 1.4 km NW of Raysville (35º20'08.9"N, 86º19'47.0"W). 2 March 2004. M. Niemiller and B. Glorioso. MTSU 336C.

Anura

Acris crepitans crepitans (Northern Cricket Frog). DEKALB CO: Adult ca. 140 m NNE of privately-owned cave on Caney Fork River (35º50'11.9"N, 85º39'00.9"W). 19 September 2004. M. Niemiller. MTSU 141A.

Bufo americanus americanus (Eastern American Toad). MOORE CO: Adult on road ca. 0.2 km SE of junction of Motlow Road and Spring Creek Road (35º20'50.2"N, 86º1'50.9"W). 1 July 2003. M. Niemiller. MTSU 123A. WARREN CO: Adult on old logging road adjacent to Hurricane Hollow Creek on Harrison Ferry Mountain (35º35'22.5"N, 85º38'21.4"W). 11 October 2003. M. Niemiller, B. Glorioso, and G. Wyckoff. MTSU 128A.

Rana catesbeiana (American Bullfrog). MOORE CO: Juvenile on road ca. 1.7 km W of junction of Rt 130 and Ledford Mill Road (35º22'13.5"N, 86º17'27.2"W). 1 July 2003. M. Niemiller. MTSU 121A.

Rana clamitans melanota (Northern Green Frog). MOORE CO: Adult on road ca 0.7 km NE of Rural Road 6 and Raysville Road (35º20'31.3"N, 86º18'24.7"W). 1 July 2003. M. Niemiller. MTSU 127A.

Rana palustris (Pickerel Frog). DEKALB CO: Adult in stream exiting privately-owned cave on Caney Fork River (35º50'07.6"N, 85º39'02.2"W). 19 September 2004. M. Niemiller. MTSU 140A. MARSHALL CO.: Adult in creek adjacent to Bradford Road ca. 2.2 km NE of Archer (35º20'27.1"N, 86º44'23.4"W). 7 December 2003. M. Niemiller and J. Spiess. MTSU 142A. MOORE CO: Adult on road ca. 0.3 km NW of junction of Spring Creek Road and Motlow Road (35º21'00.9"N, 86º18'06.6"W). 1 July 2003. M. Niemiller. MTSU 126A. WARREN CO: Adult in Hurricane Hollow Creek on Harrison Ferry Mountain (35º35'37.3"N, 85º38'21.0"W). 11 October 2003. M. Niemiller, B. Glorioso, and G. Wyckoff. MTSU 129A.

Rana sphenocephala utricularia (Southern Leopard Frog). MOORE CO: Adult on road near junction of Motlow Road and Spring Creek Road (35º20'55.3"N, 86º17'56.0"W). 1 July 2003. M. Niemiller. MTSU 122A.

Scaphiopus holbrookii (Eastern Spadefoot). MOORE CO: Adult on road ca. 0.4 km W of Rural Road 6 and Spring Creek Road (35º20'44.5"N, 86º18'02.4"W). 1 July 2003. M. Niemiller. MTSU 124A. Adult on road ca. 2.0 km SE of junction of junction of SR 55 and Raysville Road (35º20'22.6"N, 86º18'52.1"W). 1 July 2003. M. Niemiller. MTSU 125A.

**Corresponding author*

The Estado Zulia, with a surface of 63,100 km^2, is located in northwestern Venezuela and comprises a large portion of the biogeographic region denominated Maracaibo Basin (Barrio-Amorós 1998; Liddle 1946). This region is covered by dry tropical forest and xerophytic coastal zones in the north, and by tropical lowland rain forest and extensive wetlands zones in the south. The state also includes the Lake Maracaibo, at 12,780 km^2, is the largest in South America; this is filled by numerous rivers originating from the eastern versant of Sierra de Perijá and the western versant of the Cordillera de Mérida. The eastern slopes of the Sierra de Perijá, a mountain range of the northernmost Andes, are also included in the state and that watershed represents the natural limit between Colombia and Venezuela.

Scarce studies on the amphibians and reptiles from this state and particularly on the Venezuelan slope of Perijá and south of Lake Maracaibo, make the composition and geographic distribution of the local herpetofauna poorly understood. Recent herpetological records lend evidence to the great potential of the region for new contributions to the herpetofauna of Venezuela, both by the discovery of new species and new records (Barrio-Amorós 1998, 2001; Barros and Barrio 2001; Barros and Pirela 2000; Harvey et al. 2004; Manzanilla et al. 1998; Manzanilla et al. 1999; Rivas et al. 2002). Some authors foresee the occurrence of several species, not yet recorded for the country (Barrio 1998; Harvey et al. 2004), in the state.

Ongoing efforts by the staff of the herpetology section at the Museo de Biología de La Universidad del Zulia, Maracaibo, Venezuela (MBLUZ) focused on data collected during field expeditions and collections examinations, form the basis for these contributions to the herpetology of the region. In this document, we report new herpetological records and range extensions for the state. All specimens reported herein were verified by Gilson Rivas and are deposited in the amphibian and reptile collections of the MBLUZ and/or the Museo de la Estación Biológica Rancho Grande, Maracay, Venezuela (MEBRG).

Anura

Eleutherodactylus johnstonei (Coquí antillano). Municipio Maracaibo: Ciudad de Maracaibo (10°41'00"N, -71°38'22"W). July 2004. C. Solórzano. MBLUZ-A-0236. This species native to the Lesser Antilles was introduced in Venezuela about five decades ago (Barrio-Amorós 1998). Currently recorded from several cities of the country (mainly in northern Venezuela), and neighboring Colombia (see Kaiser et al. 2002 for a detailed list of inhabited towns in both countries). First state record of this exotic anuran, extending the distribution ca. 200 km northwest of the city of Trujillo in Estado Trujillo, the nearest locality recorded (La Marca 1992), and confirming the expansion of the species throughout northern South America.

Rhaebo haematiticus (Sapo hojarasquero). Municipio Machiques de Perijá: Hacienda Nevada, comunidad El Guamo, Río Yasa. 02 February 2002. T. Barros. MBLUZ-A-0173–74. The species occurs from Honduras to Chocoan Colombia, western Ecuador, and northwestern Venezuela (Frost 2004). These vouchers confirm the presence in Venezuela. Previously known from a single specimen from northwest Estado Zulia (Barrio-Amorós 2001), the eastern limit of the species. This specimen represents the southernmost record for the country, extending the range ca. 110 km south from the previous record (Barrio-Amorós 2001).

Scarthyla vigilans (Ranita vigilante). Municipio Mara: Fundo La Orchila, Sierra de Perijá (10°48'44"N, -72°21'13"W), 210 m elev. 18 October 2003. F. Rojas and E. Infante. MBLUZ-A-0186. *H. vigilans* is only know from northeastern Colombia and northwestern Venezuela. In Venezuela the range had been restricted to south of the Maracaibo Basin among the states of Zulia, Mérida, and Trujillo (Barrio-Amorós 1998; La Marca 1992; Péfaur and Rivero 2000), with one isolated record from northeast Estado Falcón (Mijares-Urrutia et al. 1998). This specimen represents the northernmost record for the species and extends the range to the foothills north of the Sierra de Perijá in the western Maracaibo Basin, about 215 km from the nearest previously known locality (Barrio-Amorós, *op. cit*.).

Testudines

Podocnemis vogli (Galápago llanero). Municipio Lagunillas: Burro Negro, embalse de Pueblo Viejo (10°10'00"N, -71°03'40"W). 07 October 1999. T. Barros. MBLUZ-R-0444. The species is found only in the Llanos of the Orinoco basin, in Venezuela and Colombia (Pritchard and Trebbau 1984). First state record, extending the distribution ca. 260 km northwest of Guanarito, the nearest locality mentioned by Pritchard and Trebbau (*op. cit.*). One of us (TBB) has information that the population established at the Pueblo Nuevo dam is the result of one or more human introductions.

Lacertilia

Anolis nigropunctatus (Aguacerito). Municipio Machiques de Perijá: Sierra de Perijá. 13 August 1975. M. Castro. MEBRG-863. The species is known in the Departamento Norte de Santander in Colombia, and two localities of estados Táchira and Trujillo in the Venezuelan Andes (Williams 1974). First state record and northernmost locality for the species. This record extends the distribution ca. 240 km from Villa Páez, estado Táchira, the nearest locality recorded (Williams, *op. cit*.).

Gymnophthalmus speciosus (Lucia). Municipio Maracaibo: Ciudad Universitaria, La Universidad del Zulia (10°40'15"N, -71°38'27"W). 06 October 2003. J. Larreal. MBLUZ-R-0777. The distribution of this species comprises Central America and northern South America (Peters and Donoso-Barros 1970). It has a wide distribution through savannas and dry forests of Venezuelan lowlands, but it was unknown from the Maracaibo Basin (Donoso-Barros 1968; Esqueda et. al. 2001; Markezich 2002; Pefaur and Rivero 2000; Rivas and Oliveros 1997). This taxon is probably part of a species complex. This is the first state record, and also the first for the Maracaibo Basin. This account extends the range ca. 257 km to the northwest of Guanare (estado Portuguesa), the nearest locality previously mentioned (Markezich, *op. cit.*).

Norops tropidogaster (Machorro). Municipio Mara: Fundo La Orchila, Sierra de Perijá (10°48'44"N, -72°21'13"W), 230 m elev. 05 June 2004. F. Rojas and E. Infante. MBLUZ-R-0794; MBLUZ-R-0797; Municipio Jesús María Semprún: Hacienda El Mirador, km 497 carretera Machiques-Colón (08°36'34"N, -72°31'42"W). 11 May 2004. C. Hernández and C. Valeris. MBLUZ-R-0803. The distribution of the species extends from southern Panama through northern Colombia, reaching northwestern Venezuela, were it is known from one locality (El Tokuko) in the foothills of the Sierra de Perijá, Estado Zulia (Donoso-Barros 1968). Second country record. The two first specimens extend the distribution ca. 117 km northward, and the third extends the range ca. 130 km towards the southeast of the single locality previously recorded for the country. The species is now known from the entire western side of the Maracaibo Basin, the eastern limit of its distribution.

Serpentes

Atractus ventrimaculatus (Culebra tierrera). Municipio Machiques de Perijá: Ayajpaina, cuenca del río Negro (10°03'00"N, -72°45'58"W), 1200 m elev. 19 April 1994. J. Urdaneta and J. C. López. MBLUZ-R-0390. *A. ventrimaculatus* has been considered an endemic species of the Cordillera de Mérida in the Venezuelan Andes (Esqueda and La Marca 2005; Roze 1966). First state record, extending the distribution ca. 260 km to the northwest of the others localities recorded.

Micrurus mipartitus anomalus (Coral). Municipio Jesús María Semprún: Hacienda El Mirador, km 497 carretera Machiques-Colón (08°36'34"N, -72°31'42"W). 11 May 2004. C. Hernández and C. Valeris. MBLUZ-R-0804. This subspecies ranges from Cordillera Oriental and the Sierra Nevada de Santa Marta in Colombia, to the Cordillera de Mérida in Venezuela (Roze 1996). This record bridges the previous distribution gap of ca. 260 km between Sierra de Perijá and the Cordillera de Mérida (Roze, *op. cit*.).

Liophis epinephelus kogiorum. Municipio Rosario de Perijá: Mesa Turik, Sierra de Perijá (10°24'44"N, -72°42'06"W), 1700 m elev. 20 March 1991. F. Herrera. MBLUZ-R-0318; MBLUZ-R-0319; Municipio Machiques de Perijá: Sierra de Perijá, Valle del Ocari, cañón del río Negro. 1300 m elev. 28 March 1990. T. Barros. MBLUZ-R-0235. The distribution previously known for this subspecies was restricted to the Sierra Nevada de Santa Marta and the western slopes of the Sierra de Perijá in Colombia (Bernal-Carlo 1994; Dixon 1983). This record of the subspecies is the first for Venezuela and the easternmost locality. This record extends the distribution of this subspecies about 40 km eastward of the locality reported by Dixon (*op. cit.*) in Colombia.

Tantilla melanocephala (Culebrita cabeza negra). Municipio Mara: Granja Santa Genoveva, road Campo Mara – Carrasquero (10°56'N, -71°56'W). 8 October 1990. J. Moscó. MBLUZ-R-0229. This species ranges from Guatemala in Central America, through South America, to northern Argentina (Peters and Orejas-Miranda 1970; Wilson 1992). Widely distributed in Venezuela (Gorzula and Señaris 1998; Lancini 1986; Lancini and Kornacker 1989; Markezich 2002; Rivas and Oliveros 1997; Roze 1966). First state record and westernmost locality for the country, with a range extension of ca. 244 km northwest of nearest record from Estado Mérida (Wilson and Mena 1980). This record fills the gap between Venezuelan Andes (Wilson and Mena, *op. cit*.) and Colombian Guajira (Pérez-Santos and Moreno 1988).

Typhlops reticulatus (Culebra ciega). Municipio Colón: río Abajo, cerca de San Carlos del Zulia (08°59'59"N, -71°55'10"W). 05 July 2003. E. Arrieta. MBLUZ-R-0761. This species is widespread over tropical South America east of the Andes (Peters and Orejas-Miranda 1970). In Venezuela, the species has been documented from the states of Amazonas, Bolívar, Yaracuy, Falcón, Portuguesa, and Barinas (Dixon and Hendricks 1979; Gorzula and Señaris 1998; Markezich. *op. cit*.; Rivas 2001; Rivas et al. 2001). New record for the Maracaibo Basin, first record from Estado Zulia, and westernmost locality known for the species, with a range extension of ca. 290 km to the west of the nearest localities previously recorded (Markezich 2002; Rivas et al. 2001).

Xenodon rabdocephalus (Culebra sapa). Municipio Jesús Enrique Lossada: Ocagui, San José de los Altos, Sierra de Perijá, 1000 m elev. 05 May 1963. G. Vargas. MBLUZ-R-0043; Cueva La Carlotica, cuenca del río Socuy, Sierra de Perijá, 1200 m elev. 22 December 1990. T. Barros and A. Viloria. MBLUZ-R-0297; cuenca del río Socuy, 1300 m elev. 17 December 2000. T. Barros and O. Guerrero. MBLUZ-R-0534; Municipio Machiques de Perijá: Cuenca del río Negro, carretera vía Toromo, Sierra de Perijá (10°03'07"N, -72°40'40"W), 100 m elev. January 2000. T. Barros. MBLUZ-R-0484; Municipio Mara: Fundo La Orchila, riecito Maché, Sierra de Perijá (10°48'44"N, -72°21'13"W), 230 m elev. 31 April 2000. E. Arrieta. MBLUZ-R-0523; 04 August 2004. E. Infante. MBLUZ-R-0834. Species is widely distributed from Mexico through Mesoamerica to Bolivia (Peters and Orejas-Miranda 1970). In Venezuela, it was only known from south of the Orinoco River, in the states of Bolívar and Amazonas (Lancini and Kornacker 1989; Paolillo 1984). The species is apparently very common in the foothills of the Sierra de Perijá. First state record and first record from the Maracaibo Basin. This is the northwesternmost locality recorded for the country, and northernmost for South America. This record extends the distribution of this species more than 700 km to the northwest of the state of Amazonas, the nearest locality recorded for the country (Paolillo, *op. cit*.), and fills a wide gap of ca. 1200 km between southern Venezuela (Paolillo 1984) and northern Colombia (Pérez-Santos and Moreno 1988).

Acknowledgments.—We thank Erick Arrieta, Carla Solórzano, and Carlos Valeris for providing some distribution records, and Eduardo Rendón and Edgar Castro for providing geographic coordinates. We also

thank Ángel Viloria, and Gilson Rivas for reviewing the manuscript and Marco Natera, Walter Schargel, and Gustavo Scrocchi for their valuable comments.

New Distributional Records for Reptiles in Central Arkansas

CHRISTOPHER A. HOWEY
and
STEPHEN A. DINKELACKER
University of Central Arkansas, Department of Biology
Conway, Arkansas, 72035, USA
e-mail [CAH]: chris.howey@gmail.com

The distribution of reptiles within Arkansas was first described in 1957 in "A Review of the Amphibians and Reptiles of Arkansas" (Dowling1957). In 2004, distributions were updated with "The Amphibians and Reptiles of Arkansas" (Trauth et al. 2004). Since that date, there have been numerous county records and range extensions for reptiles reported throughout the state, but little was ever reported for Faulkner and adjacent counties. Within the following article, we report new county records for Faulkner County and neighboring Conway County. All records were verified by Kelly Irwin (Arkansas State Herpetologist) and are currently housed at the University of Central Arkansas Museum (UCAM).

Testudines

Apalone spinifera hartwegi (Western Spiny Softshell). Faulkner Co. Caught on the East Fork of Cadron Creek ca. 7 km E of Springhill. 24 April 2006. C.A. Howey. Voucher specimen in

UCAM (UCAA119). Caught using turtle hoop trap. First county record (Trauth et al. 2004).

Chrysemys picta dorsalis (Southern Painted Turtle). FAULKNER CO. Caught on the East Fork of Cadron Creek ca. 7 km E of Springhill. June 2005. C.B. Caldwell. Voucher specimen in UCAM (UCAA120). Caught using a turtle hoop trap. First county record (Trauth et al. 2004).

Deirochelys reticularia miaria (Western Chicken Turtle). CONWAY CO. Caught in borrow pits adjacent to Cox Lake, Plumerville. May 2005. S.A. Dinkelacker and R. Bland. Photo voucher in UCAM (UCAA136). Caught using a fyke net. First county record (Trauth et al. 2004).

Graptemys ouachitensis ouachitensis (Ouachita Map Turtle). CONWAY CO. Caught near Morrilton cut-off on the Arkansas River. 14 June 2005. S.R. Adams. Voucher specimen in UCAM (UCAA122). Caught using a gill net. First county record (Trauth et al. 2004).

Graptemys ouachitensis ouachitensis (Ouchita Map Turtle). FAULKNER CO. Caught on the Arkansas River at Toad Suck Park, Conway. 2004. S.R. Adams. Voucher specimen in UCAM (UCAA123). Caught using a seine. First county record (Trauth et al. 2004).

Lacertilia

Eumeces septentrionalis obtusirostris (Southern Prairie Skink). FAULKNER CO. Caught in University of Central Arkansas Jewel Moore Nature Reserve, Conway. 16 March 2006. S. Ruane. Voucher specimen in UCAM (UCAD114). Found under pile of debris in sandy substrate with numerous ground skinks. This is a first county record and also extends the range of *E. septentrionalis obtusirostris* by four counties. This species was originally reported to only inhabit extreme western portions of the state (Trauth et al. 2004). This record extends the range ca. 170 km into the central regions of the state.

Serpentes

Agkistrodon piscivorus leucostoma (Western Cottonmouth). FAULKNER CO. Two females were collected on the East Fork of Cadron Creek ca. 7 km E of Springhill. 14 April 2006. C.A. Howey and S.A. Dinkelacker. Voucher specimens are in UCAM (UCAG123, UCAG124). An additional *A. piscivorus leucostoma* juvenile was found dead after a flood on the East Fork of Cadron Creek ca. 7 km E of Springhill. 1 May 2006. C.A. Howey. Voucher specimen in UCAM (UCAG145). First county record (Trauth et al. 2004).

Opheodrys aestivus (Rough Greensnake). FAULKNER CO. Caught in University of Central Arkansas Jewel Moore Nature Reserve, Conway. 11 April 2006. G. Adams. Voucher specimen in UCAM (UCAG113). First county record (Trauth et al. 2004).

Regina grahamii (Graham's Crayfish Snake). FAULKNER CO. Caught in a ditch on the S side of Highway 64 ca. 1 km E of Menifee. 12 June 2004. S.R. Adams. Female was pulled out of the mouth of *A. piscivorus leucostoma*. Voucher specimen in UCAM (UCAG116). First county record (Trauth et al. 2004).

Thamnophis proximus proximus (Orange-striped Ribbonsnake). FAULKNER CO. Found near large debris piles in University of Central Arkansas Jewel Moore Nature Reserve, Conway. 16 March 2006. S. Ruane. Voucher specimen in UCAM (UCAG117). First county record (Trauth et al. 2004).

Thamnophis sirtalis sirtalis (Eastern Gartersnake). FAULKNER CO. Found dead on Route 65 ca. 4 km N of Conway. 20 June 2006. R. Bland. Voucher specimen in UCAM (UCAG128). First county record (Trauth et al. 2004).

Acknowledgments.—We thank all those who contribued toward the collection of specimens for the University of Central Arkansas Museum, especially to Sara Ruane for the collection of the Southern Prairie Skink. We thank Kelly Irwin for the verification of all specimens and Stanley Trauth for further verification on the Southern Prairie Skink.

Habitat loss and fragmentation are major contributors to declines of amphibian and reptile species (Kingsbury and Gibson 2002). Changes in the land use of Illinois (especially the Grand Prairie region) have led to a decrease in the percentage of land covered by forest. Agricultural fields fragment much of this forested area; croplands cover approximately70% of available habitat within Illinois (Bretthauer and Edgington 2003). Early knowledge of herpetofaunal distributions in Illinois was chiefly due to the work of Smith (1961). A preliminary search of one of the two state parks in Clark County (Foster and Hampton 2003) indicated that the herpetological species list for this area is incomplete. Prior to these surveys 17 species of amphibians and 17 species of reptiles were documented in Clark County (Phillips et al. 1999), nineteen of these records are pre-1980 reports. Twenty-four additional species occur in surrounding counties. We hypothesized that some of these species might occur within Clark County. We surveyed approximately 280 ha of privately owned land, locally referred to as Rocky Hollow, in Clark County, Illinois and report herein, data for 14 different species.

Specimens reported were found by active searching (e.g., turning rocks and logs), by use of cover boards at our field site, or as

road kills. All specimens were verified by Christopher A. Phillips of the Illinois Natural History Survey (INHS).

Anura

Bufo woodhousii (Woodhouse's Toad). 100 m W of CR1400E at top of ravine, S of Joe's Fork Mill Creek, Melrose (39°15.51'N, 87°44.56'W). 08 May 2003. C. Drew Foster and Stephen J. Mullin. INHS 18902. Updates pre-1980 records for this species in Clark County (Phillips et al. 1999).

Testudines

Chrysemys picta marginata (× *bellii*) (Midland Painted Turtle × Western Painted Turtle). 60 m E of CR1400E along east side of dam across Joe's Fork Mill Creek, Melrose (39°15.51'N, 87°44.56'W). 12 April 2003. Stephen J. Mullin and Anthony Fennel. IHNS 18800. Updates pre-1980 records for this species in Clark County (Phillips et al. 1999).

Lacertilia

Eumeces fasciatus (Common Five-lined Skink). 150 m E of CR 1400E along ravine, S of Joe's Fork Mill Creek, Melrose (39°15.51'N, 87°44.56'W). 12 April 2003. Stephen J. Mullin and Justin Florey. INHS 18801–18802. Updates pre-1980 records for this species in Clark County (Phillips et al. 1999).

Scincella lateralis (Little Brown Skink). W of CR1400E, S of Joe's Fork Mill Creek, Melrose. 2 May 2002. Stephen J. Mullin and C. Drew Foster. INHS 18494. New county record (Phillips et al. 1999). Many individuals of both sexes and all age/size classes were seen crawling on substrate.

Serpentes

Carphophis amoenus helenae (Midwestern Wormsnake). 200 m W of CR1400E, S of Joe's Fork Mill Creek, Melrose (39°15.65'N, 87°45.37'W). 02 May 2002. Stephen J. Mullin and C. Drew Foster. INHS 2002.10 (Photo). New county record (Phillips et al. 1999).

Coluber constrictor foxii (Blue Racer). 100 m W of CR1400E at top of ravine, S of Joe's Fork Mill Creek, Melrose (39°15.51'N, 87°44.56'W). 08 May 2003. C. Drew Foster and Stephen J. Mullin. INHS 18901. Updates pre-1980 records for this species in Clark County (Phillips et al. 1999).

Diadophis punctatus edwardsii (Northern Ring-necked Snake). 100 m W of CR1400E at top of ravine, S of Joe's Fork Mill Creek, Melrose (39°15.51'N, 87°44.56'W). 8 May 2003. C. Drew Foster and Stephen J. Mullin. INHS 18900. Updates pre-1980 records for this species in Clark County (Phillips et al. 1999).

Elaphe spiloides (Central Ratsnake). 1.6 km N of Interstate 70 overpass on Cleone Road, Martinsville. 2 July 2003. C. Drew Foster and Stephen J. Mullin. INHS 19338. Updates pre-1980 records for this species in Clark County (Phillips et al. 1999). Specimen was dead on road (DOR).

Lampropeltis c. calligaster (Prairie Kingsnake). 1.6 km E of SR-49 on CR1700, Oilfield. 27 August 2003. C. Drew Foster and Stephen J. Mullin. INHS 19339. Updates pre-1980 records for this species in Clark County (Phillips et al. 1999). Specimen was DOR.

Nerodia sipedon pleuralis (× *sipedon*) (Midland Watersnake × CommonWatersnake). 40 m E of CR1400E along east side of dam across Joe's Fork Mill Creek, Melrose (39°15.63'N, 87°45.50'W). 12 April 2003. Stephen J. Mullin and Justin Florey. INHS 18799. Updates pre-1980 records for this species in Clark County (Phillips et al. 1999).

Opheodrys aestivus (Rough Greensnake). 4.8 km W of Cleone Road on CR1700, Oilfield. 5 June 2003. C. Drew Foster and Stephen J. Mullin. INHS 19337. Updates pre-1980 records for this species in Clark County (Phillips et al. 1999). Specimen was DOR.

Storeria dekayi wrightorium (Midland Brownsnake). Along ravine, S of Joe's Fork Mill Creek, Melrose (39°15.80'N, 87°45.35'W). 15 April 2004. C. Drew Foster and Stephen J. Mullin. INHS 19434. Updates pre-1980 records for this species in Clark County (Phillips et al. 1999).

Storeria o. occipitomaculata (Northern Red-bellied Snake). 120 m E of CR1400E, S of Joe's Fork Mill Creek, Melrose (39°15.51'N, 87°44.56'W). 10 May 2002. Stephen J. Mullin and C. Drew Foster. INHS 18495. New county record (Phillips et al. 1999).

Thamnophis s. sirtalis (Eastern Gartersnake). CR1400E near Joe's Fork Mill Creek, Melrose (39°15.63'N, 87°45.50'W). 30 April 2003. Stephen J. Mullin, C. Drew Foster, and Leroy Walston. INHS 18803. Supplemental record for Clark County (supports two skins submitted in May 2002 as county records).

Acknowledgments.—We thank the landowners in and around Rocky Hollow for allowing us to search their land, Robert Szafoni of the Illinois Department of Natural Resources (IDNR) for introducing us to this unique field site, the IDNR for providing financial support, and all of the field assistants (especially Patrick Enstrom, William Jordan, IV, Sarabeth Klueh, and Leroy Walston) for their help.

Since the early 1990s, numerous geographic distribution notes and articles have appeared in *Herpetological Review* regarding new amphibian and reptile county records in Illinois. Larger contributions include Crawford and Meyer (2002), Giazzon (2002), Kuhns and Crawford (2004), Markezich and Beckett (2001), Petzing et al (1998, 2000, 2002), Redmer and Ballard (1995), Tucker (1994), and Wilson (1999). This article is the second in the "Filling in the Gaps" series detailing new amphibian and reptile county records in Illinois. Specimens reported herein are housed in the Illinois Natural History Survey (INHS) amphibian and reptile collection. County records were verified by checking databases located at the Illinois Natural History Survey and recent issues of *Herpetological Review*. Databases at the Illinois Natural History Survey contain records of amphibians and reptiles from Illinois in 30 museum and private collections and unvouchered records from herpetologists and other state biologists. Using information from these databases, county-level distribution maps for all 102 species of amphibians and reptiles in Illinois have been developed and are accessible at http://www.inhs.uiuc.edu/cbd/collections/amprep/distribmaps.html. Common names follow Crother et al (2000). All Universal Transverse Mercator (UTM) coordinates are in 1983 North American datum.

Caudata

Ambystoma texanum (Small-mouthed Salamander). BUREAU CO: SW of Bureau, pond bordered by IL Rt. 26 to the ENE, floodplain forest of Big Bureau Creek to the N, and the Chicago, Rock Island and Pacific RR to the S (Zone 16: E300519m, N4572434m). 07 May 2002. J. E. Petzing and J. M. Mui. Verified by C. A. Phillips. INHS 18086. Adult found under RR tie on RR embankment at the edge of an ephemeral pond; PERRY CO.: E of Pinckneyville, flooded forest S of IL Rt. 154 and W of Beaucoup Creek (Zone 16: E292190m, N4217311m). 14 March 2002. J. M. Mui, M. J. Dreslik, J. E. Petzing, and D. B. Shepard. Verified by C. A. Phillips. INHS 18017. Adult male collected under log in floodplain forest.

Ambystoma tigrinum (Tiger Salamander). PERRY CO.: 5.7 km SW of Pinckneyville (Zone 16: E285781m, N4212648m). 01 March 2001. B. C. Jellen, J. E. Petzing, M. J. Dreslik, and D. B. Shepard. Verified by C. A. Phillips. INHS 17698. Larva; SCOTT CO.: 0.6 km S of IL Rt. 106 on the Hillview-Eldred Blacktop (Zone 15: E712126m, N4389008m. 15 March 2001. J. K. Tucker. Verified by C. A. Phillips. INHS 17895. DOR adult.

Notophthalmus viridescens (Eastern Newt). SALINE CO.: 6.75 km NW of Carrier Mills; 0.8 km E of Saline/Williamson Co. line and N of IL Rt. 13 (Zone 16: E350568E, N4177844m). 15 March 2002. D. B. Shepard, M. J. Dreslik, J. M. Mui, and J. E. Petzing. Verified by C. A. Phillips. INHS 18018. Adult female collected in wetland. Two males (INHS 18019 and 18020) were also collected on this date just east of where the female was collected.

Anura

Acris crepitans (Northern Cricket Frog). LEE CO.: Richardson Wildlife Foundation (Zone 16: E317278m, N4619314m). 12 June 2002. V. Olinik. Verified by C. A. Phillips. INHS 18210. Individual collected in pothole pond. *Acris crepitans* has now been vouchered from every county in Illinois.

Bufo americanus (American Toad). WHITESIDE CO.: Fulton Quarry, Ackers Rd. 1.6 km S of Co. Rd. 2100N; 10 km S of Thomson (Zone 15: E741078, N4640595m). 21 June 2001. J. K. Warner, M. J. Dreslik, C. A. Phillips, and J. M. Mui. Verified by J.E. Petzing. INHS 17273. Individual 38 mm SVL.

Bufo fowleri (Fowler's Toad). FRANKLIN CO.: 2.8 km NNE of Mulkeytown, 0.2 km N of Co. Rd. 900N on County Rd. 300E (Zone 16: E316001m, N4207545m). 15 June 2001. J. M. Mui, J. E. Petzing, and M. J. Dreslik. Verified by C. A. Phillips. INHS 17343. AOR adult.

Pseudacris crucifer (Spring Peeper). CARROLL CO.: 1.6 km NE jct. Mill Hollow Rd. and Scenic Ridge Rd. (Zone 15: E734139m, N4672804m). 20 June 2001. C. A. Phillips, J. K. Warner, M. J. Dreslik, J. M. Mui, and W. C. Handel. Verified by J. E. Petzing. INHS 17811. Twelve metamorphic individuals were collected from a sand pond surrounded by forest; IROQUOIS CO.: N side of County Rd. 3300N ca 1.8 km W of Co. Rd. 3000E (Zone 16: E451055m, N4538346m). 04 May 2002. D. Mauger. Verified by C. A. Phillips. INHS 18145. Adult collected in ditch; KANKAKEE CO.: E of Doney (Zone 16: E450196m, N4547171m). 14 April 2002. D. Mauger and T. G. Anton. Verified by C. A. Phillips. INHS 18140. Adult collected in shallow ditch along edge of fallow farm field.

Pseudacris triseriata (Western Chorus Frog). BUREAU CO.: SW of Bureau, pond bordered by IL Rt. 26 to the ENE, floodplain forest of Big Bureau Creek to the N, and the Chicago, Rock Island and Pacific RR to the S (Zone 16: E300519m, N4572434m). 09 April 2002. A. R. Kuhns and J. E. Petzing. Verified by C. A. Phillips. INHS 18008. One of four individuals (INHS 18008–18011) that were found under cover objects along the edge of an ephemeral pond; FULTON CO.: ENE of Marietta, jct. East Pony Rd. and North Pheasant Lane (Zone 15: E722507m, N4487176m). 13 May 2004. J. E. Petzing and W. C. Handel. Verified by C. A. Phillips. INHS 19444. Male collected from puddle along side of the road; LIVINGSTON CO.: S of Fairbury, N of E 670 North Rd. and E of N 2150 East Rd. near unnamed tributary of Indian Creek (Zone 16: E372254m, N4509530m). 18 April 2005. H. Wessels. Verified by C. A. Phillips. INHS 19658. Adult found dead in plowed field; MENARD CO.: WNW of Petersburg at Hilltop at SE corner jct. Kelly Lane and Chicago and Illinois Midland RR (Zone 16: E254708m, N4434493m). 15 May 2002. J. E. Petzing, J. M. Mui, and J. R. Jakubanis. Verified by C. A. Phillips. INHS 18179. One of two adults (INHS 18179–18180) that were collected from a flooded railroad right-of-way; OGLE CO.: NE of Daysville, north-central part of the Kyte River bottoms along S side of the Burlington Northern RR tracks (Zone 16: E308820m, N4651597m). 03 April 2004. D. Mauger. Verified by C. A. Phillips. INHS 19500. Adult captured on northwest side of shallow, open water depression rimmed by buttonbush; WHITESIDE CO.: NE of White Pigeon; E of Rock Creek, S of Pilgrim Rd. (Co. Rd. 2200N), and W of Yorktown Rd. (Zone 16: E262178m, N4642455m). 13 April 2002. A. M. Readel. Verified by C. A. Phillips. INHS 18053. One of two adults (INHS 18053–18054) that were collected from this site.

Rana blairi (Plains Leopard Frog). MOULTRIE CO.: Shelbyville Fish and Wildlife Area, West Okaw River Unit (Zone 16: E352552m, N4386682m). 26 June 2001. J. M. Mui, J. R. Jakubanis, and M. J. Dreslik. Verified by C. A. Phillips. INHS 17372. Confirms literature record of Brown and Morris (1990). Adult; PUTNAM CO.: 0.4 km S Bureau Co. line on IL Rt. 29 adjacent to Miller Anderson Woods Nature Preserve (Zone 16: E298897m, N4567294m). 19 June 2001. D. B. Shepard and A. R. Kuhns. Verified by C. A. Phillips. INHS 17319. Confirms literature record of Brown and Morris (1990). Adult collected from right-of-way adjacent to wetland along the west side of IL Rt. 29.

Rana catesbeiana (American Bullfrog). FRANKLIN CO.: 0.3 km S of Co. Rd. 1010N on County Rd. 300E by Christopher Lake (Zone 16: E316022m, N4208300m). 15 June 2001. J. M. Mui, J. E. Petzing, and M. J. Dreslik. Verified by C. A. Phillips. INHS 17342. AOR individual collected just south of where Christopher Lake meets the county road; PUTNAM CO.: 1.8 km N of IL Rt. 18 on IL Rt. 26, pond on W side (Zone 16: E305174m, N4554482m). 19 June 2001. A. R. Kuhns and D. B. Shepard. Verified by C. A. Phillips. INHS 17338. Adult; WHITESIDE CO.: W of Rock Falls, Rock River at terminus of Regan Rd. (Zone 16: E271525m, N4627523m). 03 September 2001. A. R. Kuhns, M. J. Dreslik, and J. M. Mui. Verified by C. A. Phillips. INHS 17596. Adult.

Rana clamitans (Green Frog). CALHOUN CO.: Salt Spring Rd. (Illinois side), 0.8 km W of Illinois River Rd. (Zone 15: E705716m, N4332188m). 20 August 2003. C. A. Phillips, T. R. Hunkapiller, F. T. Burbrink, and A. R. Kuhns. Verified by J. E. Petzing. INHS 19086. Female; PUTNAM CO.: 1.8 km N of IL Rt. 18 on IL Rt. 26, pond on W side (Zone 16: E305174m, N4554482m). 19 June 2001. A. R. Kuhns and D. B. Shepard. Verified by C. A. Phillips. INHS 17339. Adult; ST. CLAIR CO.: Wagon Lake (Zone 16: E260523m, N4253003m). 12 June 2002. D. B. Shepard, A. R. Kuhns, and N. J. Kuhns. Verified by C. A. Phillips. INHS 18363. Adult male.

Rana pipiens (Northern Leopard Frog). MARSHALL CO.: Ditch W side of IL Rt. 29, N of County Rd. 1005N (Camp Grove Rd.) and S of Crow Creek (Zone 16: E296653m, N4549273m). 07 May 2002. J. E. Petzing and J. M. Mui. Verified by C. A. Phillips. INHS 18089. Adult collected from roadside ditch.

Testudines

Chelydra serpentina (Snapping Turtle). FORD CO.: N of Paxton, mile marker 263 on northbound I-57 (Zone 16: E406797m, N4481782m). 25 May 2001. J. M. Mui and J. E. Rice. Verified by C. A. Phillips. INHS 17742. DOR adult; MARION CO.: U.S. Rt. 50, 0.4 km W of I-57 Salem overpass (Zone 16: E327756m, N4276872m). 01 July 2001. M. J. Dreslik and D. B. Shepard. Verified by C. A. Phillips. INHS 17741. DOR adult; SALINE CO.: 7 km NW of Carrier Mills; 0.5 km E of Saline/Williamson county line on IL Rt. 13 (Zone 16: E350046m, N4177826m). 23 April 2002. J. E. Petzing. Verified by C. A. Phillips. INHS 19657. DOR.

Chrysemys picta (Painted Turtle). GALLATIN CO.: 7 km N Old Shawneetown, Round Pond (Zone 16: E403170m, N4179400m). 08 August 2002. M. J. Dreslik and J. K. Warner. Verified by C. A. Phillips. INHS Herpetological Slide 2002.08. Adult male captured in fyke net. This specimen was not vouchered because it is a marked individual that is part of a long-term study of a floodplain lake turtle community.

Graptemys geographica (Northern Map Turtle). CASS CO.: W of Beardstown (Zone 15: E717980m, N4432104m). 22 April 2001. B. Wilson. Verified by C. A. Phillips. INHS 17906. Hatchling.

Graptemys ouachitensis (Ouachita Map Turtle). MADISON CO.: S end of Piasa Island, just S of the Jersey Co. line (Zone 15: E736433m, N4312286m). 13 July 2001. E. Ratcliff and E. Gittinger. Verified by C. A. Phillips. INHS 17904. Male.

Graptemys pseudogeographica (False Map Turtle). MADISON CO.: Piasa Island, Mississippi River (downstream, channel side; Zone 15: E737126m, N4312250m). 13 July 2001. E. Gittinger, R. Cosgriff, and B. Lubinski. Verified by C. A. Phillips. INHS 17907. Adult male.

Terrapene carolina (Eastern Box Turtle). CHRISTIAN CO.: 0.2 km N of County Rd. 990E on IL Rt. 48 (Zone 16: E298587E, N4376004m). 18 June 2001. J. K. Tucker and J. B. Towey. Verified by C. A. Phillips. INHS 18001. DOR adult.

Terrapene ornata (Ornate Box Turtle) CASS CO.: 1.6 km SSW of Beardstown Airport (Zone 15: E721015m, N4426387m). 20 June 2001. C. A. Phillips, J. M. Mui, M. J. Dreslik, and J. K. Warner. Verified by J. E. Petzing. INHS 17813. Carapace and plastron (some scutes still attached) of an adult collected in a sand prairie.

Trachemys scripta (Pond Slider). CLAY CO.: 0.6 km S of Co. Rd. 800N on County Rd. 1875E; 1.1 km S of Little Muddy Creek and N of the Little Wabash River (Zone 16: E382328m, N4285766m). 08 June 2001. J. E. Petzing, M. J. Dreslik, and J. M. Mui. Verified

by C. A. Phillips. INHS 17710. DOR adult male; MONTGOMERY CO.: 1.6 km S of Taylor Springs, 2.9 km S of IL Rt. 185 on IL Rt. 127 (Zone 16: E284945m, N4332250m). 05 May 2002. A. R. Kuhns. Verified by C. A. Phillips. INHS Herpetological Photograph 2002.06. AOR individual in the southbound lane of Illinois Route 127; it was not collected because it was an adult female.

Apalone spinifera (Spiny Softshell). JEFFERSON CO.: S of Bonnie, Atchison Creek at Chicago and Eastern Illinois RR trestle (Zone 16: E333328m, N4228164m). 17 September 2003. J. R. Jakubanis and J. E. Petzing. Verified by C. A. Phillips. INHS 19262. Juvenile.

Lacertilia

Cnemidophorus sexlineatus (Six-lined Racerunner). IROQUOIS CO.: Iroquois County Conservation Area (Zone 16:E452758m, N4538322m). 26 May 2003. T. R. Hunkapiller. Verified by C. A. Phillips. INHS 18990. Adult male.

Eumeces laticeps (Broad-headed Skink). VERMILION CO.: NNW of Humrick, Cherokee Hills Camp (Zone 16:E451880m, N4421836m). 23 May 2002. C. Montgomery. Verified by C. A. Phillips. INHS 18489. Adult male.

Serpentes

Coluber constrictor (Eastern Racer). MORGAN CO.: S of Jacksonville, jct. U.S. 67 and IL Rt. 267 (Zone 15:E737898m, N4387662m). 05 July 2000. J. K. Tucker and J. B. Towey. Verified by C. A. Phillips. INHS 17849. DOR adult.

Elaphe vulpina (Western Foxsnake). MOULTRIE CO.: W of Lanton, just S Co. Rd. 2500N on Co. Rd. 950E (Zone 16:E359969m, N4403328m). 06 July 2003. J. E. Petzing, K. S. Petzing, and E. E. Petzing. Verified by C. A. Phillips. INHS 19034. DOR adult.

Heterodon platirhinos (Eastern Hog-nosed Snake). CASS CO.: W of Beardstown (Zone 15: E717980m, N4432104m). 30 April 2001. J. K. Tucker and B. Wilson. Verified by C. A. Phillips. INHS 17900. Adult; CLINTON CO.: Eldon Hazlet State Park (Zone 16: E298347m, N4282302m). 10 May 2001. D. B. Shepard, B. C. Jellen, and M. J. Dreslik. Verified by C. A. Phillips. INHS 17731. Adult collected in woodland.

Lampropeltis calligaster (Yellow-bellied Kingsnake). FULTON CO.: WSW of Seville on Seville Rd. (Zone 15:E724212m, N4484644m). 16 April 2004. J. E. Petzing and A. M. Readel. Verified by C. A. Phillips. INHS 19427. DOR juvenile on gravel road; KNOX CO.: 0.8 km E of Warren County line on Co. Rd. 300N (Zone 15: E716325m, N4514886m). 12 August 2003. C. A. Phillips, A. R. Kuhns, and J. K. Warner. Verified by J. E. Petzing. INHS 19164. AOR sub-adult.

Lampropeltis triangulum (Milksnake). IROQUOIS CO.: 0.5 km N of N boundary of Hooper Branch Nature Preserve just W of W boundary of N unit Iroquois County Conservation Area (Zone 16: E453580m, N4540279m). 16 May 2005. C. A. Phillips. Verified by J. E. Petzing. INHS 19582. Juvenile collected under piece of corrugated tin; WASHINGTON CO.: S side of Clear Lake (Zone 16: E268993m, N4256625m). 03 June 2002. A. R. Kuhns and D. B. Shepard. Verified by C. A. Phillips. INHS 18261. Adult.

Nerodia erythrogaster (Plain-bellied Watersnake). GREENE CO: 0.5 km N Apple Creek on Hillview-Eldred Blacktop (Zone 15: E711072m, N4361073m). 29 April 2003. J. K. Tucker. Verified by C. A. Phillips. INHS 18914. DOR adult.

Opheodrys vernalis (Smooth Greensnake): PIATT CO.: County Rd. 1500E immediately N of jct. with Co. Rd. 3100N (Zone 16: E375800m, N4455100m). 15 August 2003. P. Nielsen. Verified by C. A. Phillips. INHS 19165. DOR adult salvaged from a road bordered by a cemetery and soybean and corn fields.

Pituophis catenifer (Gophersnake). PUTNAM CO.: ENE of Hennepin on IL Rt. 71 (Zone 16: E305480m, N4569859m). 10 October 2002. J. E. Petzing, C. A. Phillips, and J. F. Doolen. Verified by M. J. Dreslik. INHS 18690. DOR adult.

Storeria dekayi (DeKay's Brownsnake). BOND CO.: Crane Woods, NE of Old Ripley (Zone 16: E275890m, N4313000m). 26 September 2001. D. B. Shepard, M. J. Dreslik, J. M. Mui, A. R. Kuhns, D. Baum, and T. A. Cochran. Verified by C. A. Phillips. INHS 17721. Male collected on small rock outcrop on slope of ravine; FULTON CO.: 1.4 km N of Ogden Lane (Co. Rd. 555N) in Summum on Hammack Rd. (Co. Rd. 900E) (Zone 15: E731409m, N4462892). 20 October 2003. A. R. Kuhns and J. E. Petzing. Verified by C. A. Phillips. INHS 19279. DOR adult; GRUNDY CO.: 1.1 km SSE of Morris, W of Mud Slough (Zone 16: E382990m, N4579096m). 06 July 2001. A. R. Kuhns, J. E. Petzing, and J. M. Mui. Verified by C. A. Phillips. INHS 17454. Adult male found in flood debris in old field habitat; OGLE CO.: S side Burlington Northern RR tracks along the N boundary of the Kyte River bottoms, approx. 100 ft. W of where the bend in the Kyte River comes closest to the RR (Zone 16: E309321m, N4651555m). 20 June 2003. T. G. Anton and D. Mauger. Verified by C. A. Phillips. INHS 19106. Gravid female captured under piece of RR tie; WAYNE CO.: Forest along E side of Moutray Slough (Zone 16: E394688m, N4268057m). 11 October 2002. J. E. Petzing, J. M. Mui, M. J. Dreslik, J. F. Doolen, and C. A. Phillips. Verified by A. R. Kuhns. INHS 18745. Adult found in wood debris on forest floor.

Storeria occipitomaculata (Red-bellied Snake). FAYETTE CO.: 0.3 km S of Lorton Bridge (Kaskaskia River) on Co. Rd. 1925E (Zone 16: E336380m, N4337975m). 14 April 2002. J. E. Petzing. Verified by C. A. Phillips. INHS 18050. DOR individual collected on a gravel road; FULTON CO.: S of Marietta on the Toledo, Peoria and Western RR tracks (Zone 15: E721647m, N4485198m). 17 September 2004. J. K. Warner and J. E. Petzing. Verified by C. A. Phillips. INHS 19508. Male collected under piece of wood on the railroad.

Thamnophis proximus (Western Ribbonsnake). Cass Co.: W of Beardstown (Zone 15: E717980m, N4432104m). 08 April 2001. J. K. Tucker, P. Owen, and B. Wilson. Verified by C. A. Phillips. INHS 17902. New county record. Adult.

Virginia valeriae (Smooth Earthsnake). FULTON CO.: S of Marietta, forest along Toledo, Peoria and Western RR tracks (Zone 15: E721898m, N4484722m). 17 September 2004. J. K. Warner and J. E. Petzing. Verified by C. A. Phillips. INHS 19507. Adult male collected under rock and debris on a forested hillside.

Acknowledgments.—Field work by JEP, JMM, MJD, and CAP was partially supported by a contract with the Illinois Department of Transportation. We thank Anne Readel for permission to publish the Whiteside County Western Chorus Frog record and Valerie Olinik for permission to

publish the Lee County Northern Cricket Frog record.

We found several new locality records in the course of reviewing museum holdings of amphibians and reptiles from northeastern Louisiana. All the specimens reported here represent either new parish records (Dundee and Rossman 1989), or clarification of parish records. The majority of these help fill in distributional gaps for parishes in northeastern Louisiana, particularly in the Mississippi Alluvial Valley. Museum acronymns follow Leviton et al. (1985). Taxonomy and vernacular names used follow Crother (2000) and Crother et al. (2003). Unless indicated otherwise, specimens were verified by J. L. Carr.

Anura

Hyla chrysoscelis/versicolor (Gray Treefrog). Franklin Par: 7 mi S of Hwy 33 & Hwy 84 intersection at Roxie. 06 June 1989. M. Farr. NLU 70172–70182. New parish record.

Pseudacris crucifer (Spring Peeper). Caldwell Par: Columbia, 1.1 mi N, 0.5 mi E of Copenhagen. 08 April 1997. LSUMZ 58347. New parish record. Tensas Par: 8 mi W of Newelton. 27 February 1965. M. Carnaham. AMNH A-123120. New parish record.

Rana catesbeiana (American Bullfrog). Franklin Par: Big Creek at Baskin. 12 September 1992. Seltzer and Boudreaux. NLU 70047. New parish record.

Rana sphenocephala (Southern Leopard Frog). LaSalle Par: Hwy 460 between Nebo and Whitetail. R.Wallus, J. Hatten. 03 August 1968. NLU 19360; 5 mi W of Nickel. 12 June 1950. TU 12603. Hemphill Creek at Hwy 460, R3E, T7N, Sec. 14. 27 September 1985. TU 22018. Both verified by Harold Dundee. New parish records.

Caudata

Ambystoma maculatum (Spotted Salamander). CALDWELL PAR: 12 mi SE Chatham. 30 January 1950. F. Cagle. One clutch of eggs, TU 19523. Verified by H. A. Dundee. New parish record.

Testudines

Kinosternon subrubrum (Eastern Mud Turtle). EAST CARROLL PAR: 6 mi S Lake Providence, Hwy 134. 09 April 1966. C. B. Coburn, Jr. LSUMZ 30011. New parish record.

Graptemys pseudogeographica kohnii (Mississippi Map Turtle). CALDWELL PAR: no specific location. 13 March 1953. LSUMZ 34032. New parish record.

Terrapene carolina triunguis (Three-toed Box Turtle). RICHLAND PAR: 3 mi S of Dunn. 13 June 1966. H. Stegall. NLU 10338. New parish record.

Trachemys scripta elegans (Red-eared Slider). FRANKLIN PAR: 8 km SW of Winnsboro. 1 April 1966. D. D. Smith. KU 177218. Verified by E. Greenbaum. New parish record.

Lacertilia

Eumeces laticeps (Broad-headed Skink). CONCORDIA PAR: Slocum, ~10 mi N abandoned farm off Hwy 15 along Mississippi River levee. 03 March 1987. J. W. Tamplin. TNHC 55988, 55998, 56004. New parish record.

Sceloporus consobrinus (Prairie Lizard). RICHLAND PAR: 7 mi S Mangham in woods. CM 44166–44174. New parish record.

Scincella lateralis (Little Brown Skink). FRANKLIN PAR: 7 mi S of Hwy 33 & Hwy 84 intersection at Roxie. 29 May 1989. M. Farr. NLU 70185–70187. New parish record.

Serpentes

Agkistrodon piscivorus (Cottonmouth). FRANKLIN PAR: SE of Winnsboro. April 1969. D. D. Smith. KU 177035-177039. 17 April 1965. D. D. Smith. KU 177040–177049. Verified by E. Greenbaum. New parish record.

Crotalus horridus (Timber Rattlesnake). EAST CARROLL PAR: no specific location. 1 September 1956. J. L. Herring. FMNH 245315–245316. New parish record.

Lampropeltis getula holbrooki (Speckled Kingsnake). CALDWELL PAR: Columbia Lock and Dam sight [sic] on the Ouachita River. 3 April 1966. LSUMZ 41364. New parish record. LASALLE PAR: 2 mi E of Nickel. 12 June 1950. TU 12611. Verified by Harold Dundee. New parish record.

Lampropeltis triangulum amaura (Louisiana Milksnake). MADISON PAR: Hunter's Bend Club. 28 May 1985. K. Lofton. NLU 53792. New parish record.

Nerodia cyclopion (Mississippi Green Watersnake). CALDWELL PAR: S of Columbia. 06 April 1973. C. Corkern. NLU 36400. New parish record. RICHLAND PAR: Clear Lake. 15 April 1963. R. F. Cox. NLU 874 and 01 May 1963. R. F. Cox. NLU 875. New parish record.

Nerodia sipedon pleuralis (Midland Watersnake). OUACHITA PAR: Russell Sage about 1/4 mi off Hwy. 80 at exit 2. 3 November 1972. S. G. Walmsley. NLU 35886. Verified by Jeff Boundy. New parish record. This is the first vouchered specimen reported from northern Louisiana (Dundee and Rossman 1989; Gibbons and Dorcas 2004).

Regina grahamii (Graham's Crayfish Snake). LASALLE PAR/ CATAHOULA PAR: Gibbons and Dorcas (2004) attribute this species to LaSalle Parish. The basis for their literature record was Dundee and Rossman (1989), in which a dot straddles the border between Catahoula and LaSalle parishes. The basis for the dot was "Walters" (fide J. Boundy; LSUMZ 4824). Specimen identification has been verified by Jeff Boundy. Walters is a place name found approximately 1.1 km E of the parish line in Catahoula Parish (Anon. 1997). The same specimen was correctly used to document the Catahoula Parish museum record (Gibbons and Dorcas 2004).

Storeria dekayi (Dekay's Brownsnake). TENSAS PAR: Chicago Mills Game Management Area. 27 March 1965. E. D. Keiser. Verified by Jeff Boundy. LSUMZ 23774. New parish record.

Virginia valeriae elegans (Western Smooth Earthsnake). FRANKLIN PAR: Extension 0.5 mi SE off LA Hwy 356. 24 March 1971. D. Dosher. NLU 35430. New parish record.

Acknowledgments.–We thank the following curators and collection managers who provided assistance in obtaining museum records and specimens: L. Ford (American Museum of Natural History), J. A. McGuire (Louisiana State University Museum of Natural Science), D. Cannatella and J. Rosales (Texas Natural History Collection), and F. Pezold (NLU), J. E. Simmons (KU), H. K. Voris and A. Resetar (FMNH), and J. J. Wiens and S. Rogers (CM). We thank the following individuals for verification of museum records and specimens: Jeff Boundy (Louisiana Department of Wildlife and Fisheries, LSUMZ specimens), Eli Greenbaum (KU), and Harold Dundee (Tulane University).

New Records for Anurans from Lawrence County, Tennessee

HELEN A. MESSER
and
BRIAN P. BUTTERFIELD
Department of Biology, Freed-Hardeman University
Henderson, Tennessee 38340, USA
e-mail (HAM): mandy.messer@students.fhu.edu
e-mail (BPB): bbutterfield@fhu.edu

The geographic distribution of the amphibians of Tennessee is well documented (Redmond and Scott 1996). However, many counties in west and south-central Tennessee have not been adequately sampled. Here we provide records of four common anurans not previously recorded from Lawrence County, Tennessee (Redmond and Scott 1996). All specimens were collected while compiling a herpetofaunal list for use by park personnel at David Crockett State Park. All voucher specimens are deposited in the Austin Peay State University Museum of Zoology (APSU) and were verified by A. Floyd Scott. Collections were made under the authority of TWRA Permit No. 1494 to BPB.

Bufo fowleri (Fowler's Toad). Found on main park road adjacent to an open field and Lake Lindsay. UTM 16S, 0467005E, 3903059N. 22 July 2006. Collected by H. A. Messer. APSU 18217 (color photo). First county record.

Rana catesbeiana (American Bullfrog). Found in a small spring that feeds a millpond located behind David Crockett State Park Visitor Center. UTM 16S, 0467540E, 3902521N. 26 July 2006. Collected by H. A. Messer. APSU 18218 (color photo). First county record.

Rana clamitans (Green Frog). Found in a small spring that feeds a millpond located behind David Crockett State Park Visitor Center. UTM 16S, 0467724E, 3902577N. 14 July 2006. Collected by H. A. Messer. APSU 18219 (color photo). First county record.

Rana sphenocephala (Southern Leopard Frog). Found on the main park road adjacent to a wooded area near Crockett Falls. UTM 16S, 0467563E, 3902436N. 10 August 2006. Collected by H. A. Messer. APSU 18220 (color photo). First county record.

Acknowledgments.—We thank the David Crockett State Park personnel for their cooperation in the survey. R. Bridges and J. Walsh assisted on numerous occasions during the survey. We especially thank H. Phillips for allowing HAM to conduct this survey during work hours.

New Geographic Distribution Records of Amphibians and Reptiles in South Arkansas

HENRY W. ROBISON
Department of Biology, Southern Arkansas University
Magnolia, Arkansas 71754, USA
e-mail: hwrobison@saumag.edu

and
CHRIS T. McALLISTER
Department of Physical and Life Sciences, Chadron State College
Chadron, Nebraska 69337, USA
e-mail: cmcallister@csc.edu

In the three short years since the seminal publication of Trauth et. al. (2004) on amphibians and reptiles of Arkansas, numerous new county records have been published for species in the state (Milanovich et al. 2005; Plummer and McKenzie 2005; Solis et al. 2006; Stanley and Trauth 2005; and many others). Between February 2005 and May 2006, we discovered 12 additional, new county records for four amphibians (one salamander, three frogs) and eight reptiles (one turtle, seven snakes) from south Arkansas. Specimens were verified by Stanley E. Trauth. Township, section, and range are provided for each locality. Voucher specimens were deposited in the Arkansas State University Herpetological Museum (ASUMZ), State University, Arkansas.

Caudata

Siren intermedia nettingi (Western Lesser Siren). Ashley Co.: 3.2 km S Crossett on St. Hwy. 133 (Sec. 5, T19N, R8W). 30 May 2006. H. W. Robison. ASUMZ 30256. New county record that completely fills in hiatus in extreme southern part of state between Chicot and Union counties.

Anura

Hyla chrysoscelis/versicolor complex (Gray Treefrog). Chicot Co.: 4.8 km SE Lake Village on US 82 (Sec. 23, T16S, R2W). 07 April 2006. Dan Thomas. ASUMZ 30257. New county record that fills a gap in extreme southeast part of state; this sibling species complex has now been reported from all but three counties of Arkansas (Trauth et al., *op. cit.*, pp. 149–151, fig. 187).

Hyla cinerea (Green Treefrog). Cleveland Co: Saline River at US 79 (Sec. 27, T9S, R11W), 5.6 km NE Kingsland. 28 April 2006. H. W. Robison. ASUMZ 30254. New county record. Partially fills hiatus but species has yet to be recorded from adjacent Dallas and Lincoln counties.

Pseudacris triseriata (Western Chorus Frog). Calhoun Co.: 1.6 km E Locust Bayou at US 278 (Sec. 31, T13S, R15W). 23 Feb. 2005. H. W. Robison. ASUMZ 30253. New county record filling gap in distribution between Bradley and Ouachita counties. Robison and Rader (2005a) recently reported this frog from nearby Cleveland County.

Testudines

Sternotherus odoratus (Stinkpot). CLARK CO.: 1.6 km N Whelen Springs on St. Hwy. 53 (Sec. 22, T10S, R20W). 15 October 2005. Patrick Daniel. ASUMZ 30261. New county record that partially fills a hiatus between Dallas and Pike counties.

Serpentes

Agkistrodon contortix contortrix (Southern Copperhead). HEMPSTEAD CO.: 3.2 km SE Washington (Sec. 35, T11S, R25W). 15 October 2005. Patrick Daniel. ASUMZ 30264. New county record that fills a gap in distribution in southwestern Arkansas between Little River and Nevada counties.

Carphophis vermis (Western Wormsnake). UNION CO.: 1.6 km N Cairo on St. Hwy. 172 (Sec. 21, T17S, R17W). 27 October 2005. H. W. Robison. ASUMZ 30255. New county record. This secretive species is relatively uncommon in the southern part of the state and has been reported from only four counties: Clark, Columbia, Drew, and Hempstead (Trauth et al., *op. cit*.).

Crotalus horridus (Timber Rattlesnake). UNION CO.: 6.4 km W El Dorado (Sec. 30, T17S, R10W). 13 November 2005. Patrick Daniel. ASUMZ 30263. New county record filling a hiatus between Bradley and Columbia counties.

Lampropeltis triangulum amaura (Louisiana Milk Snake). HEMPSTEAD CO.: 3.2 km SE Washington (Sec. 35, T11S, R25W). 15 October 2005. Patrick Daniel. ASUMZ 30262. New county record that represents the southwestern most locality for the subspecies in the state.

Sistrurus miliarius streckeri (Western Pigmy Rattlesnake). UNION CO.: 13.7 km S El Dorado (Sec. 18, T19S, R15W). 08 Oct. 2005. H. W. Robison. ASUMZ 30260. New county record that fills a distribution gap between Ashley and Columbia counties (see Robison and Rader 2005b).

Storeria dekayi wrightorum (Midland Brownsnake). CLARK CO.: 1.6 km S Gurdon (Sec. 4, T10S, R20W). 13 November 2005. Patrick Daniel. ASUMZ 30259. New county record that fills a hiatus between Hot Spring and Pike counties. Specimen appears to be an intergrade *S. d. wrightorum* × *texana*; another intergrade was reported previously from nearby Hempstead County of southwestern Arkansas (Trauth et al., *op. cit*., pp. 333–336, fig. 474).

Thamnophis sirtalis sirtalis (Eastern Gartersnake). NEVADA CO.: 11.3 km W Rosston (Sec. 35, T13S, R20W). 13 November 2005. Patrick Daniel. ASUMZ 30258. New county record that partially fills a distribution gap between Hempstead and Ouachita counties.

Acknowledgments.—We thank S. E. Trauth for curatorial assistance and specimen verification, and the various collectors noted herein for providing vouchers. Specimens were collected under the authority of Arkansas Scientific Collecting Permits issued to CTM and HWR by the Arkansas Game and Fish Commission.

New County Records of Amphibians and Reptiles from Rains County, Texas

ROBERT C. JADIN
and
JESSICA L. COLEMAN
Department of Biology, University of Texas at Tyler
Tyler, Texas 75799, USA
e-mail (RCJ): snakeman1982@hotmail.com

Rains County, a small county in northeastern Texas, has been overlooked for its amphibian and reptile diversity. Although sufficient habitat exists, many common species remain undocumented. In the spring of 2006, we sampled this county periodically and collected previously unrecorded species for the county (Dixon 2000). These records help fill gaps in the distribution of the regional herpetofauna. Our nomenclature is in accordance with Crother et al. (2000) and identifications were verified by Ronald L. Gutberlet, Jr. Voucher specimens are deposited at the Amphibian and Reptile Diversity Research Center (UTA), University of Texas at Arlington, Arlington, Texas.

Anura

Gastrophryne carolinensis (Eastern Narrow-mouthed Toad). Approximately 50 m E of County Road 1490 (1 km S of Farm Road 2324). UTM (NAD 83) 15S, 0230367 N, 3636061 W, 119 m elev. 05 May 2006. Jessica L. Coleman and Robert C. Jadin. UTA A-57308. Adult male calling among large chorus of *Gastrophryne* and *Hyla versicolor*. Collected in cattle pasture (2040 h) composed of sedges, grasses, and some shrubs. Pasture partially flooded with standing water from previous night/morning rain.

Hyla versicolor (Gray Treefrog). 62.3 m N of Farm Road 779 (0.5 km W of Highway 69). UTM (NAD 83) 15 S, 0244540 N, 3637960 W, 143 m elev. 14 April 2006. Robert C. Jadin and Jessica L. Coleman. UTA A-57311. Captured in tree (2035 h) approximately 2.4 m above the ground. Tree was approximately 10 m N of small pond. Adult male found calling among large chorus of *H. versicolor* and *Acris c. crepitans*. Species identified from *H. chrysoscelis* by call. Vocal recordings and sonograms were made for verification.

Pseudacris feriarum (Southeastern Chorusfrog). Just off County Road 1490 (1.5 km W of County Road 1495). 17 May 2002. Ronald L. Gutberlet, Jr. and Carol Gutberlet. UTA A-57607–57608. An amplectant pair collected in a partially flooded field. On 05 May 2006 the authors heard several small choruses in the southwestern section of the county and a male was captured but not collected.

Scaphiopus hurterii (Hurter's Spadefoot). Farm Road 779 (10.0 km SE of Jct 3274). UTM (NAD 83) 15 S, 0249235 N, 3628237 W, 124 m elev. 20 April 2006. Robert C. Jadin, Jessica L. Coleman, and Allyson M. Modra. UTA A-57310. Found alive on road (2035 h) during moderate rainfall. Solitary adult with no chorus heard in background.

Testudines

Terrepene ornata ornata (Ornate Box Turtle). Highway 69 (2.0 km S of Jct 47). UTM (NAD 83) 15S, 0232823 N, 3646028 W, 157 m elev. 05 May 2006. Jessica L. Coleman and Robert C. Jadin. UTA R-54163. Adult female found recently run over with front half of body and carapace missing.

Lacertilia

Anolis carolinensis carolinensis (Northern Green Anole). 163 m W of Farm Road 514 (0.4 km N of Jct 2946). UTM (NAD 83) 15 S, 0250837 N, 3647152 W, 123 m elev. 25 March 2006. Robert C. Jadin and Jessica L. Coleman. UTA R-54164. (55 mm SVL, 160 mm TL). Captured on large branch (approx. 1200 h) in incomplete clear cut oak forest. Two additional green anoles observed within 60 m of vicinity.

Serpentes

Agkistrodon piscivorus leucostoma (Western Cottonmouth). 34 m NE of Farm Road 779 (8.0 km S of Jct 3274). UTM (NAD 83) 15 S, 0249289 N, 3629877 W, 138 m elev. 25 March 2006. Robert C. Jadin and Jessica L. Coleman. UTA R-54070. Adult male (545 mm SVL; 660 mm TL; 28 mm HW; 39 mm HL). Captured at an abandoned tin field (1640 h) in small open pasture. Found under 8 ft × 8 ft piece of tin 13.7 m W of small drainage canal. Approximately 20ºC on sunny afternoon. Hemipenis everted and stained. Recorded from all neighboring counties.

Acknowledgments.—We thank Ron and Carol Gutberlet for graciously donating two specimens of *Pseudacris feriarum* to this publication. Alan Byboth was generous in lending equipment for the *Hyla versicolor* recording and putting it into digital format.

New Records for Amphibians and Reptiles from Trousdale County, Tennessee

BRAD M. GLORIOSO
and
JAKE PRUETT
Department of Biology
Middle Tennessee State University
Murfreesboro, Tennessee 37132, USA

e-mail (BMG): bmg2g@mtsu.edu

Here we report new county records of amphibians and reptiles from Trousdale County, Tennessee. Unlike such regions as the Land Between the Lakes area in north-central Tennessee, and the Great Smoky Mountains in east Tennessee, Trousdale County has few records of amphibians and reptiles (Redmond and Scott 1996). The lack of records in Trousdale County can be attributed to the county's small size and scarcity of state and federal lands. With permission from landowners we were able to survey some expanses of private lands. Localities were determined by use of a Magellan handheld global positioning system (GPS) unit. Voucher specimens were verified by Brian T. Miller and were deposited into the Middle Tennessee State University Herpetology Collection (MTSU) in Murfreesboro, Tennessee. Photo vouchers were verified by A. Floyd Scott and deposited into the Austin Peay State University (APSU) database in Clarksville, Tennessee. Scientific and common names follow Crother et al. (2000). All specimens were collected under authorization of the Tennessee Wildlife Resources Agency (permit no. 1450) and the Tennessee Department of Environment and Conservation (permit no. 2004-018). Collectors were B. M. Glorioso and J. Pruett for all specimens except as noted.

Caudata

Eurycea cirrigera (Southern Two-lined Salamander). Adult in Rocky Creek under the overpass at Canoe Branch Road (36º20'54"N, 86º15'33"W). 27 February 2005. MTSU 352C.

Notophthalmus viridescens viridescens (Red-spotted Newt). Adult found in shallow pond on private property 550 m NW of Cumberland River mile marker 265 (36º19'32"N, 86º15'09"W). 27 February 2005. MTSU 351C.

Plethodon dorsalis (Northern Zigzag Salamander). Adult found under water meter cover 10 m E of Highway 231 in the 3200 block at private residence (36º20'44"N, 86º15'22"W). 27 February 2005. MTSU 350C.

Plethodon glutinosus (Northern Slimy Salamander). Adult found on private property under fallen timber 700 m WNW of Cumberland River mile marker 265 (36º19'27"N, 86º15'19"W). 04 May 2005. MTSU 349C.

Anura

Acris crepitans crepitans (Eastern Cricket Frog). Adult found at edge of shallow pond on private property 550 m NW of Cumberland River mile marker 265 (36'32"N, 86º15'09"W). 27 February 2005. MTSU 160A.

Rana catesbeiana (American Bullfrog). Juvenile found in spring on private property 350 m SW of Cumberland River mile marker 265 (36º19'12"N, 86º15'01"W). 27 February 2005. MTSU 159A.

Rana clamitans melanota (Northern Green Frog). Juvenile found in Rocky Creek under the overpass at Canoe Branch Road (36º20'54"N, 86º15'33"W). 27 February 2005. MTSU 158A.

Rana palustris (Pickerel Frog). Juvenile found in spring on private property 350 m SW of Cumberland River mile marker 265 (36º19'12"N, 86º15'01"W). 27 February 2005. MTSU 157A.

Rana sphenocephala (Southern Leopard Frog). Adult found on road during rainy night in the 2500 block of Oldham Road (36º22'49"N, 86º13'27"W). 28 April 2005. J. Pruett. MTSU 156A.

Testudines

Trachemys scripta elegans (Red-eared Slider). Adult found DOR in the 2100 block of State Highway 25 (36º24'16"N, 86º11'18"W). 04 May 2005. APSU Photo Voucher 18181.

Lacertilia

Eumeces fasciatus (Common Five-lined Skink). Adult found under tin 45 m E of Highway 231 in the 3200 block at private residence (36º20'43"N, 86º15'20"W). 04 May 2005. MTSU 50L.

Serpentes

Coluber constrictor constrictor (Northern Black Racer). Adult encountered on private property at edge of limestone bluff 175 m NW of Cumberland River mile marker 265 (36º19'25"N, 86º14'56"W). 4 May 2005. APSU Photo Voucher 18179.

Lampropeltis triangulum triangulum (Eastern Milksnake). Subadult found under tin 50 m E of Highway 231 in the 3200 block at private residence (36º20'46"N, 86º15'19"W). 4 May 2005. APSU Photo Voucher 18180.

Regina septemvittata (Queen Snake). Juvenile found under rock at edge of Rocky Creek under the overpass at Canoe Branch Road (36º19'32"N, 86º15'09"W). 4 May 2005. MTSU 179S.

Guia de Sapos da Reserva Adolpho Ducke, Amazônia Central (Guide to the Frogs of Reserva Adolpho Ducke, Central Amazonia), by Albertina P. Lima, William E. Magnusson, Marcelo Menin, Luciana K. Erdtmann, Domingos J. Rodrigues, Claudia Keller, and Walter Hödl. 2006. INPA, PPBio, Fundación BBVA, CNPq, Attema, Manaus, Brazil. Hardcover. 168 pp. Sent free to recognized investigators. ISBN 85-99387-01-4.

CÉSAR L. BARRIO-AMORÓS
Fundación AndígenA, Apartado Postal 210
5101-A Mérida, Venezuela
e-mail: cesarlba@yahoo.com

Amazonia is among the most well investigated areas of high biodiversity in the world. Regarding herpetology, some places have a long tradition of surveys, and thus, are reasonably well known. Unfortunately, these areas are few in comparison to the total extent of Amazonia, which is also one of the most threatened zones in the world. Some of these well-studied locations are Santa Cecilia (Duellman 1978) and Cuyabeno (Vitt and de la Torre 1996), both in Ecuador, Manu (Morales and McDiarmid 1996), Llullapichis (Schulter et al. 2004), Iquitos (Rodriguez and Duellman 1994), and Cusco Amazonico (Duellman 2005) all in Peru, and the Reserva Florestal Adolpho Ducke (RFAD) close to Manaus, in Brazil (e.g., Martins and Oliveira 1998 for snakes). The book reviewed here provides a comprehensive review of the amphibians of the last of these localities.

Guia de Sapos da Reserva Adolpho Ducke, Amazonia Central is well designed and illustrated and is printed on plasticized paper, making it very bright, attractive, and durable. The book starts with a preface by William E. Duellman, a table of contents, and an introduction placing the area into context and giving a general idea about the importance of the Reserva Adolpho Ducke and the scientists who have studied there. The occurrence of taxonomically difficult groups, such as *Colostethus* and the *Leptodactylus pentadactylus* group, in the area is also noted.

This is followed by a chapter on the general biology of anurans, including information about the confusion associated with common names, color and defence, predation, reproductive mode, and developmental strategies (aquatic – 21 species; semiterrestrial – 19 species; terrestrial – 8 or 9 species, and egg deposition and

direct development on the dorsum of the female – 2 species). Frog call types (including mating, aggressive, release and distress calls) are also explained at an introductory level. All these components of the introduction are very well illustrated by good examples taken from many of the species occurring in the area.

A short chapter on how to use the guide is also provided. This points out that the book is aimed at ecologists, tourist guides and the general public. Given the audience, the characters used for identification purposes are geared toward live identification in the field and, as the authors explain, the many photos provided, supplemented by a figure (page 47) showing the principal names of body parts that appear in the text, are intended to be adequate for that purpose.

The species accounts making up the bulk of the guide include representatives of the Bufonidae (5 species), Centrolenidae (1 species), Dendrobatidae (3 species, one unnamed), Hylidae (17 species), Leptodactylidae (16 species), Microhylidae (6 species), and Pipidae (2 species), totaling 50 species at the RFAD. Each account appears on one page of two columns (one in Portuguese, the other in English) and includes data on distribution in RFAD, general distribution, a superficial description, similar species, and natural history. The facing page usually displays four or five photos of each species, all of very high quality, including ventral views, multiple dorsal patterns (if intraspecifically variable), animals in amplexus, calling males, nests and tadpoles. The result is an excellent overview of the batrachofauna of the area.

A short bibliographic section containing all references appearing in the text follows, as well as a page introducing each of the authors of the book. The book closes with acknowledgments, and introductions to the BBVA (Banco Bilbao Vizcaya) Foundation (which financed the printing) and the PPBio (Program for Biodiversity Research).

I found no errors in the book and I only can congratulate the authors for providing such jewel for my library. The book is not currently for sale but, in a real act of philanthropy by the authors and financers, it will be sent to researchers and especially to local schools and students who could not normally afford it.

One caveat is that in books dealing with Neotropical amphibians, the names of the species can change (often as result of new phylogenetic data). In this respect, the book was probably in press when the two most recent important revisions of Neotropical amphibians, Faivovich et al. (2005) and Frost et al. (2006), appeared. Accordingly, the names listed in the book corresponding to the revised taxonomy of these authors are: *Bufo granulosus* = *Chaunus granulosus*, *Bufo marinus* = *Chaunus marinus*, *Bufo proboscideus* = *Rhinella proboscidea*, *Epipedobates femoralis* = *Allobates femoralis*, *Hyla boans* = *Hypsiboas boans*, *Hyla* cf. *brevifrons* = *Densropsophus* cf. *brevifrons*, *Hyla geographica* = *Hypsiboas geographicus*, *Hyla granosa* = *Hypsiboas cinerascens* (see also Barrio-Amorós 2004), *Hyla lanciformis* = *Hypsiboas lanciformis*, *Hyla minuta* = *Dendropsophus minutus*, *Phrynohyas resinifictrix* = *Trachycephalus resinifictrix*, *Adenomera andreae* = *Leptodactylus andreae*, *Adenomera hylaedactyla* = *Leptodactylus hylaedactylus*, *Lithodytes lineatus* = *Leptodactylus lineatus*.

Further, taxonomic issues in Neotropical amphibians are not well resolved for many species. Thus, in the book, the species *Atelopus spumarius*, *Bufo granulosus*, *Scinax ruber* (or, more likely, a *S. x-signatus* complex), both *Adenomera* species (now *Leptodactylus*), and *Elachistocleis bicolor*, are members of complexes that could soon be subject to name changes as species boundaries become established through systematic research.

Taxonomic issues aside, I have only two minor criticisms of the work. First, the general distribution section of the species accounts is too general and sometimes does not include all confirmed species in adjacent regions. For example, there is no mention of the presence of *Hyla boans*, *Hyla granosa*, *Osteocephalus buckleyi*, *Phyllomedusa bicolor*, *P. tarsius*, *P. vaillanti*, *Scinax garbei*, *S. ruber*, *Leptodactylus petersi*, *Chiasmocleis hudsoni*, *Ctenophryne geayi*, and *Synapturanus salseri* in Venezuela, where these species are reported or well known (Barrio-Amorós 2004). On the contrary, two species (*Ceratophrys cornuta* and *Leptodactylus rhodomystax*) are listed as present in Venezuela, although neither is supported by vouchers or included in the most recent Venezuelan checklist (Barrio-Amorós 2004). Second, a local guide such a this would be an ideal place to include more detailed descriptions of species calls, even if only in an onomatopoeic way. Indeed, a future edition of this book would benefit by the inclusion of a CD with all possible calls from the area, as was provided by Ibañez et al. (1999) for the Barro Colorado area in Panama.

Tales from the Thébaïde is a collection of articles, essays, and speeches by Peter C.H. Pritchard. In the publisher's news release it is stated that "a cheloniological thread thus runs through his Tales from the Thébaïde, as he (Pritchard) expands the study of his favorite animals into commentaries upon the universe itself, and includes brilliant, erudite, and always humorous accounts of his adventures in many lands seeking further insight into the shelled reptiles." There are some golden threads within this book, but they do not run through it. In several places the thread gets snarled and in other areas an out-of-place stitch is added to try to tie a chapter to chelonians.

The book starts with a collection of stories about Archie Carr in the chapter "The Master Turtler." These stories bring new views of the greatest turtle researcher and advocate of the twentieth century, from Carr's changing views on the use of sea turtles to his opinions on personal recognition. Pritchard gathered these stories though his long friendship with Carr, first as a Ph.D. student and then as a colleague. This is followed by a chapter on "Tortoise Life" which meanders from feeding strategies, including an interesting piece on early morning forays by Aldabra Tortoises, to the learning ability of tortoises—Pritchard relates how his captive tortoises are known to ram their heater when it is not on during cold weather. This chapter has other interesting stories and bits of natural history, but does not flow well from point to point.

After the introductory chapters, the remaining 26 chapters are organized into six sections: Galápagos, Sea Turtles, Schooldays, Personalities and History, Speeches, and Essays. Pritchard, one of the leading turtle experts in the world, provides personal insights that include important information not normally provided in the turtle literature. This is especially true in the chapters dealing with the Galápagos and sea turtles.

In a Galápagos tortoise chapter, "Whatever Happened to the Pinta Tortoise?," Pritchard details a survey of Pinta Island to try to find a live female tortoise for Lonesome George. During their expedition they located a number of sites with tortoise shells and bones, but not live tortoises. Pritchard's conclusions on the "extinction" of this race of turtles include a discussion on how the whalers collected the smaller females because they were more easily carried and came to the lower elevations of the island for nesting. This skewed the harvest, which led to a male-dominated population that could not sustain itself.

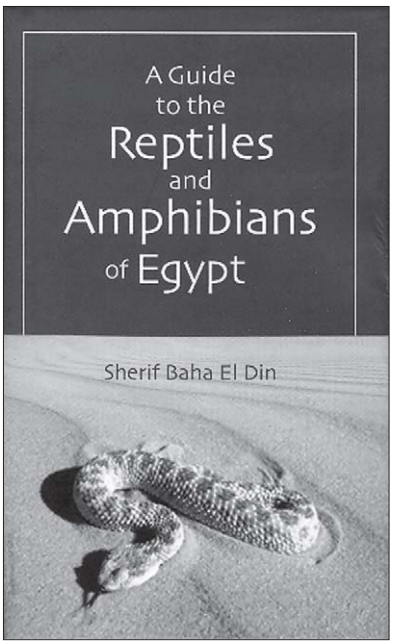
A sea turtle chapter, "Life and Death in Oaxaca," provides a very graphic, but important view of the commercial sea turtle business in Mexico during the 1970s. The efficient harvest and processing of turtles highlights how they can be easily exploited. The owner of the processing plant, Antonio Suarez, is shown to be an intelligent man with a different view on the role of sea turtles. Many turtle conservationists would not be able to see past the negative side of Suarez's business of killing sea turtles. The information contained in this chapter makes the entire book worthwhile.

The chapters "Old Masters Remembered" and "Origins" give an interesting look into 1950s Northern Ireland boarding school life and the semi-aristocratic background of the Pritchard clan, but has little connection to turtles. These chapters might have worked better earlier in the book, although the book would not have been diminished if they were omitted all together.

The chapter on "Greenie Remembered" was fun to read. We have all had a college friend similar to Greenie. They are always willing to help, provide conversation, and freeload, but normally they were not willing to tough it out in primitive field camps as Greenie did in Suriname and other locales. The description of the early Suriname field station shows the difficulty accessing remote areas. The lack of roads and expansive mud flats in front of the beach made it a challenge to get to and set up camp at the premier turtle beach in the country. Those same barriers probably also allowed the beach to persist.

The collections of speeches and essays give several different viewpoints into Pritchard's thoughts on turtle conservation, turtle conservationists, and the future of conservation in general. Several previously published papers and speeches appear in other sections of this book. In all over one third of the chapters consist of previously published material.

In the essay section, there is a long chapter on why Pritchard set up his personal Thébaïde, the Chelonian Research Institute. The publisher includes the French dictionary definition of thébaïde — "an intellectual retreat, a remote place, away from the bustle of life, where conversation, scholarship, and scientific and literary discourses are sacred." This chapter gives a history on the formation of the Institute and the diverse collection of turtle specimens, representing a greater species diversity than most major research museums. In parts of the chapter, Pritchard seems to vent on es-



tablished research institutions and their funding sources for not treating the Chelonian Research Institute as an equal. This gives the chapter a negative tone, when it should have been one of the most positive chapters highlighting Pritchard's legacy.

Peter Pritchard has provided an interesting view into his life and research. It is too bad that there is not more structure to the work as a whole. The sections about Schooldays and Personalities would have been workable had they been located at the beginning of the book and included a better thread connecting them to the overarching chelonian theme. This problem, and the general organization of the book, should have been corrected by the publisher when the early drafts of manuscript were received. However, despite some negative issues raised in this review, *Tales from the Thébaïde* is an interesting foray into the thoughts and experiences of an interesting gentleman who is one of the modern day turtle gurus.

A Guide to the Reptiles and Amphibians of Egypt, by Sherif M. Baha El Din. 2006. American University in Cairo Press, 113 Sharia Kasr el Aini, Cairo, Egypt (www.aucpress.com). xvi + 360 pp., 48 pls. Hardcover. US $34.95. ISBN 997-424-979-8.

DAVID C. BLACKBURN
Department of Herpetology, Museum of Comparative Zoology
Harvard University, Cambridge, Massachusetts 02138, USA
e-mail: dblackb@fas.harvard.edu

The herpetology of North Africa has received increasing attention during the past twenty years, mostly from European researchers. Several introductory guides to the herpetofauna have been produced for the region, which is treated variously as North Africa (Schleich et al. 1996), Northern Africa (Salvador 1996), or the Sahara (Le Berre 1989), as well as for specific countries or territories, including Morocco (Bons and Geniez 1996) and Western Sahara (Geniez et al. 2004). While not the earliest study of amphibians and reptiles in North Africa, John Anderson's (1898) zoological study of Egypt was the first major contribution to studies of the reptiles and amphibians of this region. This detailed and scholarly work firmly established Egypt as an important crossroads of the herpetofauna of Africa, the Mediterranean, and the Middle East. Nearly a century after the publication of Anderson's work, Mostafa Saleh's (1997) *Amphibians and Reptiles of Egypt* provided a synthesis of more recent knowledge of Egypt's herpetofauna, including major works such as the checklist by Hyman Marx (1968) and descriptions of new species such as *Bufo kassasii* (Baha El Din 1993). However, most species accounts in Saleh's book are very short and most details on the biology and ecology were taken from the literature rather than personal experience. Until now, Saleh's (1997) work has been the only recent summary of the study of Egypt's amphibians and reptiles.

Sherif Baha El Din's new book, *A Guide to the Reptiles and Amphibians of Egypt*, surpasses previous work on the Egyptian herpetofauna and stands as perhaps the most thorough book focused on the reptiles and amphibians of any single African country. Unlike many other treatments of the North African herpetofauna, this book is written by an Egyptian and sets an excellent precedent for future work by African herpetologists. The book builds on Baha El Din's extensive and expert knowledge of the biology and distribution of Egypt's reptiles and amphibians, which were the focus, at least in part, of his recent doctoral thesis work at the University of Nottingham. This work is of a high caliber and is an extremely important contribution to both African and Mediterranean herpetology.

As Saleh's (1997) book is the only other recent extensive treatment of Egypt's herpetofauna, it is appropriate to make comparisons between it and the recent work by Baha El Din (2006). In many ways, the layout of the two books is very similar. Baha El Din's book begins with several brief chapters introducing the reader to Egyptian herpetology, climate, geological history, patterns of herpetofaunal diversity, relevant habitats, and conservation. Each chapter is short and concise but contains sufficient details and references to enable further pursuit of the topics. These chapters build on similar sections found in Saleh's book that detail the history of Egyptian herpetological research, the relevant habitats of Egypt, and general remarks about Egypt's herpetofaunal diversity. In general, the sections of Saleh (1997) are more extensive, but the briefer descriptions by Baha El Din (2006) are very appropriate for a field guide. The photographs of representative habitat types included by Baha El Din are less numerous than those found in Saleh (1997) but still provide a general idea of diversity. Both books consist mostly of species accounts and keys for determining genera and species. For example, Baha El Din's section on lizards begins with a key to the families that occur in Egypt, which is then followed by sections on each family that contain keys to both genera and species as well as accounts for each. The keys of the two books are quite similar and those of Baha El Din's book are essentially refined versions of the other that include additional species, additional characters, and/or more precise descriptions. Several of the keys, including those for anurans, lizards in general, gekkonids in particular, and snakes, are accompanied by useful illustrations showing characters of interest; drawings of head scales are also presented for all of the Egyptian leptotyphlopid and typhlopid snake species. Brief accounts are provided for each genus and include comments on diagnostic features and geographic range.

The species accounts in Baha El Din's book are extensive and much more detailed than those of Saleh (1997). These accounts are full of useful information regarding biology and ecology, most of which Baha El Din gained from personal experience with the species. Each species account contains a map showing the geographic distribution on a half-degree grid, a list of synonymies, including at least those relevant to Egypt, the English and Arabic

common names, and thorough sections on taxonomy, variation, habitat and ecology, range, distribution within Egypt, and conservation status. In general, each section is well referenced. Information on the conservation status comes from the recent Global Amphibian Assessment (IUCN et al. 2004) and the ongoing, but still unpublished, Global Reptile Assessment. Except for the photographs placed in the center of the book, all information for a given species is found in the species account. The detailed species accounts and consolidation of information for each species makes this book a truly handy field resource.

Baha El Din specifically details information regarding particular museum collections on which the distribution and taxonomic data is based. In some species accounts, especially for species that are poorly known in Egypt (e.g., *Ptychadena schillukorum*, *Leptotyphlops nursii*) or those with interesting or isolated populations (e.g., *Eumeces schneideri*), museum specimens are referenced by catalogue number. In other species accounts, Baha El Din discusses and redetermines particular museum specimens that were previously assigned to a given species; some of these redeterminations result in significant changes in the distribution maps (e.g., *Acanthodactylus pardalis*). The citation of museum specimens is a welcome departure from most other books focused on the reptiles and amphibians of African countries. Impressively, all but one of the 118 species included in the book were documented based on voucher specimens (single exception: *Psammophis punctulatus*), although these are not referenced in the text.

Much of the data regarding geographic distributions comes from Baha El Din's work over more than 20 years. His extensive fieldwork and examination of museum specimens has resulted in the refinement of the species distribution maps presented by Saleh (1997) and includes many new localities. Baha El Din takes a very systematized approach to presenting geographic distribution data; each species has a map on which its presence is indicated on a half-degree base map. This is an improvement over many other works that include maps with overlapping point localities, which can be difficult to interpret. Baha El Din inferred the presence of species in areas intervening between known localities by using ecological data to refine a minimal complex polygon around the known localities. This is entirely appropriate and quite useful. However, this does not entirely explain a few distribution maps of species with discontinuous ranges in which there are seemingly isolated cells where a species is predicted to occur (e.g., *Hemidactylus turcicus*, *Stenodactylus petrii*, *Lytorhynchus diadema*). A gazetteer of localities including coordinates is an excellent accompaniment to the geographic distribution data presented in the species accounts. By explicitly presenting both known localities and predicted areas of occurrence, the distribution maps should be very useful for guiding future field research in Egypt. Scientific names are accompanied by information on synonymy that, appropriate for a guide, is restricted to that which is most relevant to Egypt. In addition, common names in both English and Arabic are provided; names in Arabic script can be found in Saleh (1997). If readers are interested in other common names for North African animals in Arabic or other languages, including Tamasheq, Tebu, or Fulfulde, they should refer to Monteil (1951) and Le Berre (1989).

Color photographs of living specimens accompany most species descriptions. These images are generally sufficient and significantly add to the species descriptions by illustrating coloration and even details of morphology such as snout shape (e.g., *Scincus scincus*, Fig. 74). In comparison to the photographs of Saleh (1997), those presented by Baha El Din are of higher quality and exhibit both greater detail and better color.

I found very few errors in the text. A very minor exception is the statement on page 145 that there are 16 lacertids in Egypt; there are actually 17 species, as correctly indicated by the number of species accounts.

Both museum and field researchers will enjoy Baha El Din's *A Guide to the Reptiles and Amphibians of Egypt*. The extensive species accounts, which include references to museum specimens, are an excellent resource for collections-based research, whereas the range maps, ecological data, photographs, and compact size ensure that this will be the single resource used by interested professional or amateur herpetologists traveling in Egypt. I highly recommend this book to anyone interested in the zoology of Africa, the Mediterranean, or the Middle East. It will be difficult to surpass such an excellent work.

PUBLICATIONS RECEIVED

Turtles in My Sandbox, by J. K. Curtis. 2006. Sylvan Dell Publishing, 976 Houston Northcutt Blvd., Suite 3, Mt. Pleasant, South Carolina 29464, USA (www.sylvandellpublishing.com). 31 pp. Hardcover. $15.95. ISBN 78-0976882374.

I shared this book with a member of its target audience, an el-

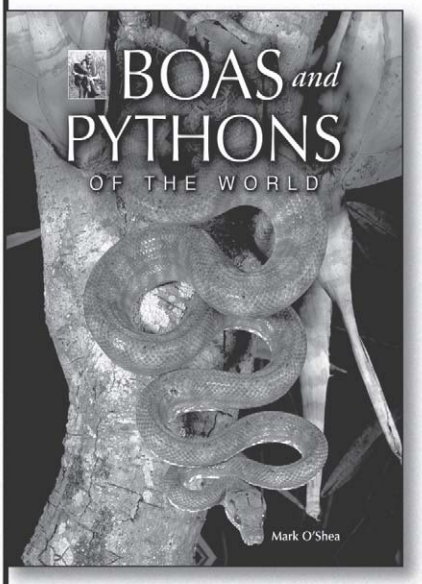
ementary school level child, as well as two younger children, and it was well received in every case. The brief text and excellent illustrations tell the story of a little girl who finds a diamondback terrapin nest in her sand box and then with the advice of experts she and her mother headstart the hatchlings for nine months. The youngsters are then released into the ocean under the watchful eye of terrapin conservationists. The controversies regarding headstarting are, of course, not mentioned, but the text is biologically accurate. I liked that the eggs were incubated *in situ*, and that the hatchlings were fed somewhat natural foods. It would have been advisable to recommend hand washing to a child maintaining turtles. The text implies that it is difficult to find good advice on terrapin husbandry and conservation, so the book could have listed some of the good sources that are available on the web and in print. The last three pages of the book contain outlines for making fun turtle cut-out toys. A great gift for the 4–8 year old you know.

***Russell Burke**, Department of Biology, Hofstra University, Hempstead, New York 11549, USA; e-mail: russell.l.burke@hofstra.edu.*

Bibliotheca Cordyliformium, by Klaus Adolphs. 2006. Squamata Verlag, Sankt Augustin, Germany (www.squamata.de). 304 pp. Hardcover. € 42,00 (approx. US $55.00). ISBN 978-3-9805086-1-2.

This book is intended as a reference work on the lizard families Cordylidae and Gerrhosauridae. It begins with an up-to-date listing of the 120+ species and subspecies in these groups, complete with synonyms and a short statement (in German) of their distribution. The bulk of the work is occupied by a comprehensive bibliography, with over 1370 numbered entries listed alphabetically. The entries span the period from Seba's *Thesaurus* in 1734–35 to mid-2006 and include even the most obscure references in all languages. An extremely valuable feature is the inclusion of the complete (unabbreviated) titles of journals—a feature lacking in most bibliographies of any kind and one that is especially critical for those working with early systematic literature. For all references for which the content of the paper is not self-evident from the title, a short summary of the taxa dealt with and the nature of the data presented is provided. This is usually in German, but some references are accompanied by their original English abstracts. Separate indices are provided to authors, co-authors and editors, species and subspecies, and subjects (more than 100 keywords). This handsomely produced volume will be invaluable for those interested in cordylids and gerrhosaurs and is recommended for herpetobibliophiles and those studying African herpetology.

Avian and Exotic Animal Hematology and Cytology, 3rd Edition, by Terry W. Campbell and Christine K. Ellis. 2007. Blackwell Publishing (www.BlackwellVet.com). ix + 287 pp. Hardcover. US $149.99. ISBN 978-0-8138-1811-5.



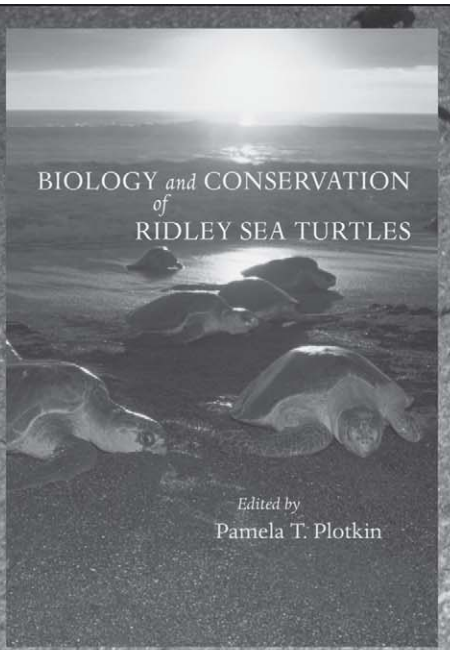
This is the third edition of a standard veterinary work on the hematology and cytology of a diversity of vertebrates, including amphibians and reptiles. Herpetological information is included chiefly in chapters 2 (Hematology of Reptiles, 31 pp.), 3 (Hematology of Amphibians, 9 pp.), and 6 (Comparative Cytology, 83 pp). Topics covered include blood sample collecting and handling, cytological sampling techniques, morphology, laboratory evaluation and disease responses of erythrocytes, leucocytes, and thrombocytes, blood parasites, hematopoiesis, and normal and abnormal cytology. Most examples are drawn from species commonly kept as pets, but others derive from sea turtles, crocodilians and other, more exotic taxa. Also, there is an extensive section dealing with the hematology of birds and shorter chapters treating fish and small mammals (exclusive of dogs and cats). A separate chapter on diagnostic microscopy using wet-mount preparations focuses on fish, but is relevant for amphibian disease detection and treatment. Two appendices provide a useful guide to stains and solutions and give hematologic values for selected taxa, including 33 reptile and eight amphibian species. A 27-page bibliography of over 1000 references completes the book, which is illustrated throughout by color cytological, parasitological, and blood film micrographs. Of obvious direct relevance to veterinarians dealing with herpetological patients, this book will also be valuable to those academics, zoo professionals, and very serious herpetoculturists with an interest in amphibian and reptile diseases and parasites. However, the treatment of some relevant topics with an extensive literature, such as lizard malaria, is relatively superficial; other topics, such as chytridiomycosis in amphibians, which one might expect to be treated in the cytological and/or wet-mount preparation sections of the book, are not mentioned.

Ecology and Ecosystem Conservation, by Oswald J. Schmitz. 2007. Island Press, 1718 Connecticut Avenue, NW, Suite 300, Washington, D.C. x + 166 pp. Hardcover. US $40.00, ISBN 978-1-59726-048-0; Softcover. US $19.95. ISBN 978-1-59726-049-7.

This small book is aimed at a broad audience and is part of the series Foundations of Contemporary Environmental Studies. It uses specific examples from conservation biology to present underlying principles of modern ecology and to explain why ecosystem and biodiversity conservation are crucial to dealing with current environmental problems. Among the topics included are climate change, carrying capacity, habitat fragmentation, and population dynamics. Amphibians and reptiles are mentioned in several places, with sea turtles serving as a focal taxon in the chapter "Viability of Threatened Species." This book is perhaps most appropriate for an undergraduate audience in introductory courses in environmental science or conservation biology, but its clear, simple style and real-life examples make it accessible to laypeople in general. Biologists whose research interests are far removed from ecology might also find this a convenient introduction to some of the main issues in conservation biology.

Back Issue Clearance for Publications of The Herpetologists' League

In an effort to reduce the need for storage space, The Herpetologists' League will be holding a clearance sale of back issues of its publications at the Joint Meetings in St. Louis in July 2007. Single issues of *Herpetologica* or *Herpetological Monographs* ($5°°) or complete volumes of *Herpetologica* ($20°°) will be available for purchase as long as supplies last. Only cash or checks (USD$, drawn from a US bank) will be accepted, and these sale prices are valid only when purchasing back issues in person at JMIH'07. Sale hours will be from 1330–1700 h on 12–15 July. Please contact Steve Mullin (<sjmullin@eiu.edu>) with any questions.



Boas and Pythons of the World
MARK O'SHEA

In *Boas and Pythons of the World*, renowned snake expert Mark O'Shea takes readers on an exciting continent-by-continent journey to look at these snakes in their native habitats. Stunning color photographs and intriguing stories from O'Shea's encounters with these snakes in the wild bring these reptiles to life. Addressing the dire risks they face, O'Shea discusses what can be done to help save what are among our most fascinating reptiles.

160 pages. 155 color plates. 2 maps. 9 1/2 x 12 1/2.

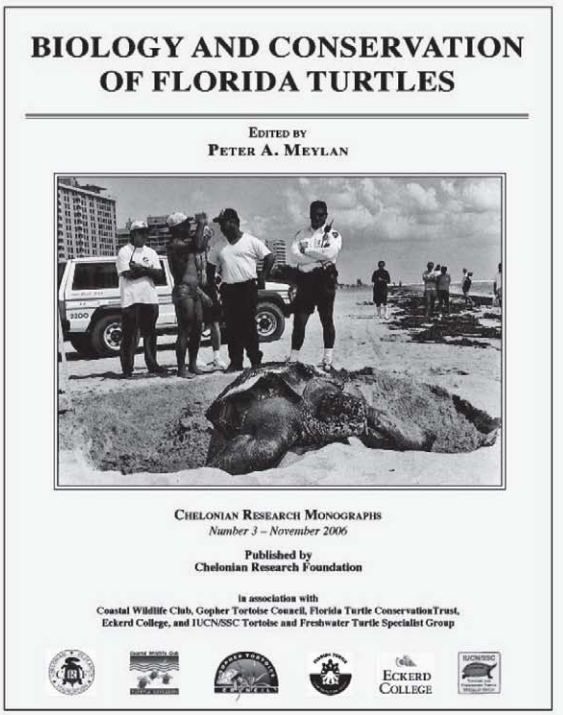
BIOLOGY AND CONSERVATION OF RIDLEY SEA TURTLES
edited by Pamela T. Plotkin

"An excellent book that fulfills a real and substantive need in the areas of marine biology, vertebrate biology, and conservation biology. A 'must read' for anyone interested in marine turtles."
—James R. Spotila, author of *Sea Turtles: A Complete Guide to Their Biology, Behavior, and Conservation*



"An excellent overview of these two species, this long-awaited volume provides a wealth of information."
—Karen A. Bjorndal, University of Florida

Pamela T. Plotkin brings together the world's experts on the genus *Lepidochelys* to present the first comprehensive, book-length examination of these fascinating animals. Featuring the writings of noted experts including Peter C. H. Pritchard, Jack Frazier, Rene Márquez-M., and Donna J. Shaver, the volume synthesizes over a half century of research. With chapters focused on evolution, development, genetics, physiology, reproduction, migration, and conservation, this book combines a wealth of knowledge and describes an agenda for further research.

$60.00 hardcover

Now Available

Chelonian Research Foundation is pleased to announce the publication of Volume Number 3 of *Chelonian Research Monographs*, published November 2006:

BIOLOGY AND CONSERVATION OF FLORIDA TURTLES

Edited by
PETER A. MEYLAN

Comprehensive summary of all 25 freshwater turtle, marine turtle, and tortoise species occurring in Florida, including descriptions, distributions, habitats, ecology and natural history, threats, status, and conservation. Thorough species accounts and family overviews by 39 leading turtle biologists with extensive field experience with Florida turtles. Foreword by Anders G.J. Rhodin. 376 pages, 235 figures, including 163 full-color photographs and 32 color maps.

Both hard and soft cover editions are available for immediate delivery.

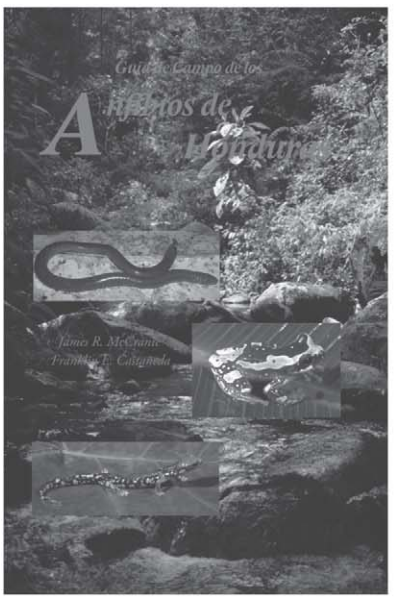
A New Herpetological Circular from the Society for the Study of Amphibians and Reptiles

Herpetological Circular 36

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
A FIFTY YEAR HISTORY: 1958 TO 2007



John J. Moriarty and Breck Bartholomew

The SSAR History provides highlights of the first 50 years of the Society's existence. This publication includes complete listing of 50–yr, 40+–yr, and 25+–yr members, Society Officers, Publications, Editors, Annual Meetings, and Committee Chairs. The history is illustrated in color with meeting photos and publication covers. A must have for anyone interested in SSAR. iv + 60 pp. July 2007, in conjunction with 50th Annual meeting. ISBN 978–0–916984–72–4

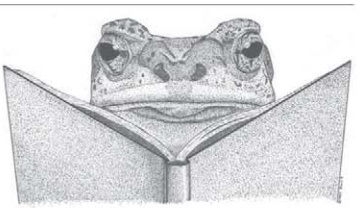
Prices: Prepublication (*SSAR members only*)		After December 31, 2007	US $10.00
first copy -	US $7.00	**USA Shipping** : First copy	US $2.00
additional copies	US $5.00	Additional copies	US $1.00

Send orders to: Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158-0517, USA. *Telephone / fax* 801-562-2660; *email*: ssar@herplit.com. Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may be charged to VISA or MasterCard (Account number and expiration date must be provided). SSAR membership details and a complete list of Society publications can be obtained on request from the Publications Secretary.

Guia de Campo de los

Anfibios de Honduras

James R. McCranie & Franklin Castañeda



This first Spanish edition of the *Amphibians of Honduras* is completely revised and updated with description of 124 species in 38 genera and 10 families. Taxonomic keys are provided in English and Spanish. The color plates include photographs of 121 species and 24 habitats. Eighty-five dot distribution maps cover the distribution of all 124 species. An additional 8 maps illustrate physical and political characteristics of Honduras.

Published with the financial support of the World Bank and RANA.

Specifications: 320 pages, 80 color plates, 6 x 9 inches. Hardcover (ISBN: 1-932871-11-1) $20.00. **Shipping:** $4.00 within the USA, $9.00 non-USA addresses.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution or Natural History notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order form will be sent prior to publication. These are also available upon request from the Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pdf/Adrates.pdf).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Central Michigan University, Department of Biology, 217 Brooks Hall, Mt. Pleasant, MI 48859, USA. Periodicals postage paid at Mt. Pleasant, MI 48859 and at additional mailing offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Breck Bartholomew, PO Box 58517, Salt Lake City, UT 84158, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Please notify Breck Bartholomew, SSAR Publications Secretary (contact information below), regarding missing or damaged issues.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 760		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 760	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2007 in the Society for the Study of Amphibians and Reptiles are as follows: **REGULAR** membership US$60 (Student $30)—includes *Journal of Herpetology* and *Herpetological Review*; **PLENARY** membership US$80 (Student $45)—includes *JH*, *HR*, and annual subscription to the *Catalogue of American Amphibians and Reptiles*; **INSTITUTIONAL SUBSCRIPTION** $115—includes JH and HR. Additional fee for airmail postage outside USA $35 for one year. Additional membership categories available on the SSAR webpage: http://www.ssarherps.org/pages/membership.html.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its newsjournal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Breck Bartholomew, SSAR Membership Office, P.O. Box 58517, Salt Lake City, Utah 84158, USA. Fax: (801) 453-0489; e-mail: ssar@herplit.com.

Future Annual Meetings

2007 — Saint Louis, Missouri, 11–16 July (with ASIH, HL)
2008 — Montreal, Canada (with ASIH, HL)
2009 — Portland, Oregon (with ASIH, HL)

About Our Cover: *Cruziohyla craspedopus*

Amazon and Western Leaf Frogs were recently placed in the phyllomedusine genus *Cruziohyla* (Faivovich et al. 2005. Bull. Amer. Mus. Nat. Hist. 294:1–240). The Amazon Leaf Frog, *Cruziohyla craspedopus* (Funkhouser, 1957), occurs in the upper and central Amazon Basin where it is locally common but seldom observed by humans owing to its habitat, the understory and canopy of primary and transitional rainforest. Syntopic anurans include *Phyllomedusa bicolor*, *Ecnomiohyla tuberculata*, *Trachycephalus resinifictrix*, and *Nyctimantis rugiceps*. Amazon Leaf Frogs possess the remarkable ability to alter the color on the periphery of the iris from tan to yellow. Dermal fringes adorn the lips and shanks, and the dorsal pattern is reminiscent of a leaf laced with fungi or lichens. They rest by day on leaf surfaces with their appendages tightly adpressed and the eyes concealed by reticulate palpebra. This crypsis is advantageous in evading two of their principal predators: monkeys of the genus *Pithecia* and *Cebus*.

In the upper Amazon Basin, *A. craspedopus* is most easily observed in *várzea*, seasonally flooded forest (including *bajial* and *tahuampa* in Peru), comprised of *Ficus* sp. (*Renaco*) – *Attalea butyracea* (*Shapaja)* associations, and marginal habitat (*restinga)* where alluvial soils support an understory of *Guadua, Heliconia, Phytelephas*, and *Bellucia*, and a mixed canopy including *Pourouma, Clusia, Pausandra*, *Couma*, and *Couratari*. The advertisement call, a soft "wort," is produced infrequently as males converge upon communal nesting sites during the dry season. Suitable sites include stagnant water in buttress pans and branch axils of *Renacos*; hollow stumps; logs with catch basins; rot holes; isolated pools; and artificial habitats caused by cutting. Up to two dozen large eggs are deposited in adhesive masses on twigs, bark, and over-hanging vegetation. The larvae grow in water stained with tannin from rotting leaves. Adults and eggs are consumed by Cat-eyed Snakes, *Leptodeira annulata*. Tadpole predators include larval odonates, lycosid and ctenid spiders, and aquatic hemipterans and coleopterans. Metamorphs are tan, pale lavender, or bluish dorsally. Upon emerging, they ascend to the canopy, where they feed on diminutive arthropods.

The cover image was made in 1993 in the río Chambira drainage system, Loreto, Peru, by **William W. Lamar** with a Pentax LX 35mm SLR camera, a Vivitar Series 1 105mm macro lens stopped down to f/22, and a Vivitar Series 1 flash with Fujichrome Velvia film pushed to ISO 100. Lamar's fieldwork in the Neotropics spans 35 years, and his efforts in northeastern Peru have produced nearly 400 species of amphibians and reptiles. Lamar is an Adjunct Professor of Biology at the University of Texas at Tyler. He coauthored *The Venomous Reptiles of Latin America* and *The Venomous Reptiles of the Western Hemisphere* with Jonathan A. Campbell. He leads natural history tours for GreenTracks, Inc., http://www.greentracks.com. Recent travel has taken him to Amazonian Brazil and several islands in the tropical Pacific.

PHOTO BY AUSTIN STEVENS

SSAR BUSINESS

Open Letter to Membership

SSAR will celebrate its 50th Anniversary in 2007. Special activities will take place during the Joint Meeting of Ichthyologists and Herpetologists (JMIH) in St. Louis, 11–16 July. The major events associated with SSAR's Anniversary are scheduled for 13 July. These events feature a symposium organized by Jonathan Losos entitled "Herpetology in the Age of Genomics." Jim Murphy and Kraig Adler will be the Masters of Ceremonies for a special SSAR Banquet that evening. The SSAR/HL auction will follow the banquet. And, of course, everyone is invited to attend the Business meeting on July 15. A link to registration on our website (http:www.ssarherps.org) will be available in January. Registration can be for the entire meeting or only for the day of the SSAR celebration.

—Roy McDiarmid, SSAR President
—Robin Andrews, SSAR Immediate Past President

SSAR Election Results

Results of the 2006 SSAR election are as follows:

President-Elect: Brian Crother
Secretary: Marion Preest
Treasurer: Kirsten Nicholson
Board Members (Regular): Paul Chippendale, Tiffany Doan
Board Member (Conservation): Stephen Richter
Board Member (Regional Society): Travis LaDuc

Thanks to all of the nominees who agreed to stand for positions and to Maureen Kearney (Elector).

Student Travel Awards Silent Auction

The SSAR STAC announces the Twelfth Annual Frameable Art Silent Auction to be held at the 2007 SSAR meeting in St. Louis, Missouri from 11–16 July. Preferred donations include herp-related photos, line drawings, prints, paintings, plates, engravings, or anything frameable, if not already framed. If you are interested in donating an item (tax deductible for U.S. residents), please email ALDRIDGE@SLU.EDU. If you will be bringing silent auction items with you to the meeting, you may drop them off at the service desk with Sharon Brookshire. Make sure you specify SSAR silent auction.

SSAR Student Travel Awards: Call for Applications

Ten awards of US $200 each are available. An applicant for a travel award must be a student and a member of SSAR, must not have previously received a travel award from SSAR, and must be the first author of a paper or poster to be presented. Application package must include: 1) letter signed by his/her major advisor or

department chair that states: he/she is not completely funded for travel from another source; 2) an official copy of the poster or paper abstract to be presented; 3) a self-addressed, stamped envelope. If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. Qualified applicants are pooled and winners are drawn at random. Students from local meeting site and current members of the SSAR Travel Awards Committee are excluded from applying for a travel award. Applications must be postmarked by 15 April 2007. Award checks will be disbursed at the meeting. Send application package to: Dawn S. Wilson, Southwestern Research Station, P.O. Box, 16550, Portal, Arizona 85632, USA, or for further information email: dwilson@amnh.org.

NEWSNOTES

NAI Honors Conant and Stebbins in Albuquerque

The National Association for Interpretation (NAI) is an organization made up of 5000 members dedicated to advancing the profession of heritage interpretation. Individual members include those who work at parks, museums, nature centers, zoos, botanical gardens, aquariums etc.

Interpreters of natural history have relied on the two herpetological Peterson Field Guides for decades. For this and many other reasons, at its 2006 meeting, held 7–11 November, NAI bestowed awards to both Roger Conant (posthumously) and Robert C. Stebbins.

NAI's president Evelyn Kirkwood decided to create the first-ever Lifetime Achievement Award for Conant. The NAI professional awards committee chose Stebbins for the Senior/Retired Interpreter Award.

At the award banquet, the 400 members in the audience enjoyed historical photos of both awardees projected on screen, and a video segment of Roger Conant accepting his David S. Ingalls, Jr. Award of Excellence at the Cleveland Museum of Natural History in 1996. Dr. Stebbins chose not to make the long trip, so his friend and colleague, Alan Kaplan of East Bay Regional Park District in California, accepted on his behalf.

For more information about NAI, visit the website at: www.interpnet.com.

Robert Inger Honored in Malaysia

Robert Inger, Curator Emeritus at Chicago's Field Museum of Natural History, was honored recently with the Panglima Setia Bintang Sarawak (PSBS) award. A special investiture was held in January 2007 at Kuching, during which Inger was presented the award from the Yang di-Pertua Negeri Tun Datuk Patinggi Abang Muhammad Salahuddin. Inger received the award in recognition for 50 years of research on Sarawak, much of which has focused on cataloguing the enormous diversity of the Bornean herpetofauna. Beginning in 1956, Inger's field work at Sarawak, often in collaboration with graduate students and fellow scientists, has resulted in the description of more than 50 new species, nearly all of which are Bornean endemics. As noted in the press release accompanying the award ceremony: "His work has been a vibrant source of inspiration to a great throng of herpetologists, students and field biologists from all over the world. His most outstanding characteristic, however, is his unflagging kindness and generosity in helping generations of young herpetologists, including many from Malaysia."

Salahuddin confers the PSBS award to Dr. Inger. Penerangan photo, courtesy of the Field Museum of Natural History.

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (rwh13@csufresno.edu) well in advance of the event.

16–20 April 2007—First Mediterranean Herpetological Congress, Marrakech, Morocco. Information available from the Congress website: www.ucam.ac.ma/cmh1.

14–18 April 2007—14th ARAV Conference, Association of Reptile and Amphibian Veterinarians, New Orleans, Louisiana, USA. Information: http://www.arav.org/.

31 May–2 June 2007—Southwest Partners in Amphibian and Reptile Conservation, First Annual Regional Meeting, Albuquerque, New Mexico, USA. Information: http://chelydra.unm.edu/swparc/.

20–23 June 2007—31st International Herpetological Symposium, Toronto, Canada. Information: http://www.kingsnake.com/ihs/.

11–16 July 2007—50th Annual Meeting, Society for the Study of Amphibians and Reptiles; 87th Annual Meeting, American Society of Ichthyologists and Herpetologists; 65th Annual Meeting, The Herpetologists' League. St. Louis, Missouri, USA. Information: http://www.dce.ksu.edu/jointmeeting/.

3–6 August 2007—5th Conference on the Biology of Plethodontid Salamanders: Symposium in Honor of David B. Wake. Instituto de Biologia, UNAM and ECOSUR, San Cristobal de la Casas, Chiapas, México. Information: http://www.ibiologia.unam.mx/barra/congresos/salamandra/salamandra.html.

3–7 September 2007—Venom Week 2007. Tucson, Arizona, USA. Information: http://www.ocme.arizona.edu.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Michele Johnson** or **Josh Hale**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can be found at: http://www.herplit.com/contents.

Ontogenetic Color Changes in Lizards Driven by Behavioral Changes

Tails with conspicuous coloration are a common feature in juveniles of reptiles, amphibians and fish, a characteristic that is usually lost in adults. Most studies have associated the presence of conspicuous tails with deflection of predators to a less vulnerable body part or with visual signaling for social behavior. The authors questioned why juveniles lose that coloration if it provides a specific advantage. Previous studies suggested that differences in threats encountered by juveniles and adults could explain the change in coloration; the authors propose a new alternative: changes in behavior may change the costs and benefits of bright coloration. They studied whether changes in body pattern and tail color in *Acanthodactylus beershebensis* are associated with behavioral differences before and soon after the ontogenetic color changes. Foraging mode and microhabitat use of one-week-old hatchlings (with bright blue tail and yellowish stripes on dorsum) and 3 week-old juveniles (that have already loss the bright coloration) were recorded in the Northern Negev desert (Israel). During 20-minute observation intervals, movements per minute (MPM) and proportion of time spent moving (PTM) were calculated to estimate foraging mode, and the proportion of time spent in open gaps between shrubs (PTO) was used to quantify microhabitat use. Two additional sympatric lacertid species (*Mesalina guttulata* and *Acanthodactylus boskianus*) that do not exhibit an ontogenetic coloration change were also studied. A MANOVA found significant differences in MPM, PTM, and PTO between hatchlings and juveniles of *A. beershebensis*; newly hatched lizards with conspicuous blue tails move more and spend more time in the open microhabitat than brown-tailed juveniles. No significant differences were found between MPM and PTM in hatchlings and juveniles of *M. guttulata*. However, a significant difference was found in PTM in *A. boskianus*: juveniles move less than adults (i.e., exhibit a safer foraging mode). The authors suggest that predation risk is a possible explanation for the behavioral change associated with the ontogenetic changes in color and body pattern in *A. beershebensis*; in addition they discuss alternative hypotheses and the possibility that multiple factors could be operating together.

Dietary Changes in the Cannibalistic Morphs of *Ambystoma* Salamanders

In salamanders, cannibalistic morphology is an example of phenotypic plasticity, expressed as the development of prominent teeth and a larger head. The benefits of cannibalism are associated with faster growth rate and larger size, while the costs are associated with the fitness loss from eating relatives and being more vulnerable to predators. In most cases studied, cannibalistic morphs ate mostly conspecifics; however, is has been found that some cannibal morphs do not eat conspecifics at all. It appears that the degree of cannibalism depends on the density of heterospecific vs. conspecific prey. Still, it is unknown if cannibal morphs are obligatory cannibals or if they can change their diet through time. The authors studied a population of *Ambystoma tigrinum nebulosum* located at Kettle Pond, Colorado, which includes cannibalistic morphs. The dietary components of cannibalistic and typical morphs were sampled four times, at one-week intervals. Each individual sampled was measured and weighed, and their stomachs were flushed. Stomach contents were identified by prey type and prey length, and later quantified by dry weight. MANOVA found differences between typical and cannibalistic forms in the consumption of chironomid larvae, mollusks, and terrestrial invertebrates; also, only cannibalistic forms ate conspecifics. However, after the second week of the study period, the diet of cannibal forms changed, decreasing the amount of conspecifics and showing a composition more similar to the typical forms. A significant difference in prey size was also found between the two groups,

but only in the first week of sampling; during weeks 2-4, there was no size difference found given the decrease of prey size in cannibal forms. In conclusion, the authors found that cannibalistic forms are not obligatory cannibals and that diet components changed through time. The authors discussed the increase of dietary niche overlap between the two morphs, the impacts on resource partitioning and the evolutionary advantages of alternative trophic morphologies.

DENOËL, M., H. H. WHITEMAN, AND S. A. WISSINGER. 2006. Temporal shift of diet in alternative cannibalistic morphs of the tiger salamander. Biological Journal of the Linnean Society 89:373–382.

Functional Trade-Off Between Swimming and Running in *Triturus* Salamanders

Structural requirements for multiple competing functions often result in a compromised morphology that does not optimize the performance of either function. Aquatic vs. terrestrial trade-offs in locomotor performance are common, as the same functional system must perform dissimilar tasks under different environmental conditions, and a single phenotype cannot maximize different traits at the same time. Theory predicts that morphological adaptations for efficient locomotion in aquatic environments will reduce terrestrial locomotor ability and vice versa. *Triturus* salamanders are an especially interesting case, given that different species spend different amounts of time in water or on land, predicting different degrees of trade-off between optimal terrestrial or aquatic phenotypes. The authors compared body elongation, head width, fore- and hindlimb length, tail length and height in females of 10 species of *Triturus*, in addition to swimming and running speed from trials performed in a linear track. Data were analyzed using non-phylogenetic correlation tests, and by incorporating phylogenetic information using independent contrasts and phylogenetic generalized least squares; morphological variables were corrected for body size using Mossimann's (1970) multivariate method. Axillary-groin distance was negatively correlated with forelimb length and head width, but no association was found between relative axilla-groin distance and tail length or height. Species with longer tails and shorter axilla-groin distances swam faster, and surprisingly, species with shorter axilla–groin distances also ran faster. No negative correlation between running and swimming speed was found; that is, there was no evidence of a trade-off between swimming and running speed at the interspecific level. The authors discuss the lack of association between body elongation and swimming speed, considering the current understanding of mechanics of movement in water. In addition, alternative scenarios are considered: the association of body elongation with a swimming characteristic other than speed, and the association of body elongation with a function outside locomotion.

Parthenogenesis in Captive Komodo Dragon Females

Parthenogenesis, the production of offspring without fusion of male and female gametes, is rarely seen in vertebrates. In this study, the authors report findings of parthenogenetic offspring in Komodo Dragons (*Varanus komodoensis*) from captive females kept in isolation from males. Genetic fingerprinting was used to identify the parentage of the offspring of two females kept in separate UK zoos, one of which had never been in contact with a male. In both, all produced offspring were homozygous for all loci, although not each other's identical clones. One of the females later resumed sexual reproduction after mating with a male, suggesting that parthenogenesis in Komodo Dragons is facultative and not a fixated state, and that asexual reproduction occurred when mating was not possible. Results provide evidence for previously overlooked threats for the Komodo Dragon populations that are already under strong extinction pressures: 1) the reduction of genetic variability, as parthenogenesis entails complete homozygosity of the entire genome, and 2) sex ratio bias in the population, in this case favoring males, as females are the heterogametic sex (WZ). The authors explore the consequences for maintaining genetic variability in the reproduction program based on captive individuals, and describe the need for further studies on the genetic load of the parthenogenetic offspring, the frequency of parthenogenesis in captivity and in wild populations, and its consequences on fitness.

Population Status of the Black Caiman: Towards a Conservation Strategy

The Black Caiman (*Melanosuchus niger*) was once an abundant, wide spread predator present in the entire Amazon basin and neighboring river drainages. In the last century there has been an estimated 90% reduction of its population due to the strong hunting pressure and habitat loss in the area. To increase the amount of information available to establish a conservation program, the authors studied microsatellite polymorphisms in 169 individuals from seven populations in Brazil, Ecuador, and French Guiana. Allelic diversity and heterozygosity levels were used to estimate current population status. Isolation by distance was measured using a Mantel test and a Reduced Major Axis (RMA) regression between genetic and geographic distances, and population structure was assessed using FIS and FST coefficients. Genetic diversity and heterozygosity was high in all populations (highest in two

populations in central Amazon of Brazil and lowest at the Ecuadorian population), despite the absence of hatchlings and large breeders in some populations, evidence of population decline. The authors discuss the difficulty of assessing loss of genetic diversity after significant but recent threats and the effect of migration on the observed results. An overall differentiation in the allelic variation was found among populations, with tests indicating a significant population structure at all loci. Even those populations in close proximity were significantly different at the genetic level, a result probably associated with differential occupation of habitats (e.g., black water swamps vs. estuarine waters) and/or sex-biased dispersal. The authors highlight the necessity of collecting more data on the biology and ecology of the black caiman and recommend concentrating the management efforts on the protection of key sites and the implementation of sustainable habitat use programs to ensure ecological functions and gene flow.

Differences in Tropical vs. Temperate Diversity: An Integrated Evolutionary and Ecological Approach

The higher species diversity observed in tropical versus temperate regions has been a pattern subject of multiple studies, but is still not completely understood. Most research addressing this pattern has focused on the differences between the two regions in ecological processes, diversification rates, and/or environmental variables. Recently, the tropical conservatism hypothesis was proposed as an explanation that combines ecological factors that are correlated with species richness patterns with the evolutionary and biogeographic processes that ultimately shape these patterns. In this paper, the authors present an empirical test for the three major predictions of the tropical conservatism hypothesis: 1) groups with high tropical diversity originated in the tropics and have dispersed to the temperate zones only recently, 2) dispersal of tropical groups in temperate areas is limited by their inability to tolerate freezing temperatures in the winter, and 3) a large number of extant groups originated in the tropics, because the tropics were more geographically extensive until ~30–40 millions years, when the temperate zones expanded. Phylogenetic analysis (based on combined mitochondrial and molecular data), ancestral area reconstruction (using parsimony and likelihood reconstructions), molecular dating methods (combining molecular branch length information and fossil calibration points, using penalized likelihood analysis) and ecological niche modeling (based on museum locality records and 19 climatic variables) were used to test these predictions in hylid frogs. Among other results, the authors found that hylids have low species richness in areas that have been colonized more recently, independently of whether those regions are tropical or temperate, supporting the time-for-speciation effect: more species accumulate in regions where a group has been present longer. No significant relationship was found between diversification rates in clades and the latitudinal midpoint of those clades. Also, they found that the northern limit ranges of many tropical clades converge in Middle America; however, the ecological niche modeling suggests that the climatic variable shaping geographical limits is not the extreme freezing temperatures, but the temperature seasonality over the year. The authors further discuss the extent and limitations of the tropical conservatism hypothesis and the caveats found based on their results.

Evolution of Acoustic Communication in Amazonian Dendrobatid Frogs

Studies on the evolution of anuran communication have examined the relationship between calling features, geographic variation, receivers' (usually females) preference, and breeding success of the senders and receivers. However, before the receivers can react to a signal, it first must be detected over the background noise, and in species that breed together, heterospecific signals can be considered as masking noise. A possible outcome of the selective effects of masking interference is the spectral partitioning between calls of co-occurring species. Yet, masking interference depends not only on the call's frequency, but the range of sensitivity of the receiver. In addition, as body size constrains calling frequency, selection of call frequency can be confounded with selection on body size. To test the masking interference effects on communication traits, the authors studied the variation in the Amazonian frog *Allobates femoralis* in relation to the presence of *Epidedobates trivittatus* (which has a similar calling activity and an overlapping call frequency). Eight sites, four with both species present and four with only *A. femoralis* were studied in Brazil, Colombia, French Guiana, and Perú. To characterize calls, the authors recorded males of *A. femoralis* and all active species at each site and calculated temporal and spectral parameters for each population. To establish response-frequency curves, the authors recorded male *A. femoralis* phonotactic reactions towards conspecific synthetic calls representing variations in frequency of the average call of the population, but keeping the temporal properties constant. In addition, they examined the correlation between variation in communication traits of *A. femoralis* and the presence of acoustically coactive species, and studied the geographic covariation between call frequency traits, response-frequency traits and body size. The authors found that the occurrence of *E. trivitattus* was a significant predictor of the variance in the traits associated with the frequency-response curve: when *E. trivitattus* was present the curve was narrower due to an increase in the response low frequency and asymmetric due to a decrease in the response of the high frequency. In addition, the variation of the communication traits was not associated with the number of coactive species and the geographic covariation was correlated with call frequency or response-frequency range.

Color Variation and Alternative Reproductive Strategies in *Lacerta vivipara* Females

In reptiles, color variation within sexes is usually associated with the existence of alternative behavioral strategies in males, and with thermoregulation or predator avoidance in females. However, as females have been observed to play an active role in mate choice, it has been suggested that their differences in coloration might also reflect different reproductive strategies. The authors studied *Lacerta vivipara* females, which exhibit a ventral color variation ranging from pale yellow to bright orange. The population studied is located on Mont Lozère, Southern France, and is divided into two adjacent zones: one with high structural microhabitat diversity and high lizard density and the other with low structural diversity and low density. Females were captured annually from 1989 to 2002 and kept in the laboratory until parturition; weight and snout-vent length of females and hatchlings were recorded. Color phenotype was determined by comparison with a color reference and then confirmed using discriminant analysis based on several parameters measured with a spectrophotometer. Color variation throughout life and heritability of this variation were estimated, and reproduction success and survival were compared between phenotypes in relation to year of capture and density of each phenotype. Results show differences in clutch size, clutch hatchling success and clutch sex-ratio among females of different phenotypes. The authors discuss the diverse responses to density and environmental conditions and suggest alternative strategies that could maintain the color variation in females in this population.

Effects of Machinery and Modern Agricultural Practices on *Glyptemys insculpta*

The expansion of the agricultural frontier has reduced natural habitats and displaced many species, while many others have become an active part of the transformed landscape. Although disturbance-resistant species have persisted in agricultural landscapes for a long time, the introduction of modern machinery has created new threats for them. The authors studied the impact of current agricultural practices on *Glyptemys insculpta* turtles in 330ha that include deciduous forest, cattle pastures and crop fields in southern Québec, Canada. Turtles were captured during 1995, 1998–1999, and marked, aged, sexed, measured and photographed. Injuries on the limbs and carapace were recorded, and a carapace mutilation index is proposed to standardize and quantify severity of injuries. In addition, a total of 30 individuals were equipped with transmitters for radio-telemetry tracking; each turtle was located once or twice a week during the 1998–1999 period. Results indicate that turtles are being strongly affected by the new machinery as determined by the type and severity of the injuries found. Six of the 30 individuals tracked died as a result of agricultural activities. Estimated annual mortality rates for adults were 0.10 and 0.13, and for juveniles 0.18 and 0.17, for 1998 and 1999 respectively. Mutilation rates in the carapace reached 90±3%, while mutilation in the limbs reached 21.2%. Differences in carapace injuries were found between juveniles and adults, probably associated with differences in body size and habitat use. In addition, most of the injuries were found on the right side, probably related with habitat preferences and movement patterns. The authors argue that estimated mortality rates are evidence that the population is unsustainable in the long term and suggest that slight changes in the height of the machinery (disc mowers) used will not only make a significant difference in the effect of harvesting in turtles, but will also provide some benefits to agricultural production.

SAUMURE, R. A., T. B. HERMAN, R. D. TITMAN. 2007. Effects of haying and agricultural practices on a declining species: The North American wood turtle, *Glyptemys insculpta*. Biological Conservation 135:581–591.

Back Issue Clearance for Publications of The Herpetologists' League

In an effort to reduce the need for storage space, The Herpetologists' League will be holding a clearance sale of back issues of its publications at the Joint Meetings in St. Louis in July 2007. Single issues of *Herpetologica* or *Herpetological Monographs* ($5°°) or complete volumes of *Herpetologica* ($20°°) will be available for purchase as long as supplies last. Only cash or checks (USD$, drawn from a US bank) will be accepted, and these sale prices are valid only when purchasing back issues in person at JMIH'07. Sale hours will be from 1330–1700 h on 12–15 July. Please contact Steve Mullin (<sjmullin@eiu.edu>) with any questions.

ZOO VIEW

Not every zoo keeper begins the day collecting rattlesnakes on the grounds of their place of employment. In this article by Jan Johnson on the Arizona-Sonora Desert Museum, one of her most interesting descriptions (in my view) is the remarkable number of rattlesnakes found over a fourteen year span (once, 177 snake encounters in a single year). What a wonderful setting for the zoo herpetologist.

Jan and I worked together at the Dallas Zoo years ago before she went to Arizona, but we never found a single rattlesnake on zoo grounds, even though Western Diamondback rattlers were relatively common in outlying areas at that time . . . no wonder she left for greener snake pastures!

Another interesting feature in Jan's article is the new daily venomous reptile presentation, which reminds me of the earlier exhibit at Tierpark Berlin-Friedrichsfelde in Germany. In 1956, the snake farm or vivarium opened, housing a large number of venomous snakes. Werner Krause started working at the Tierpark shortly after the building opened and was known as "Snake Farmer Krause." Krause accumulated many varieties of venomous snakes, some from his private collection, which were "milked" in front of zoo visitors (Fig. 1). This exhibit was unique in a zoological garden for it was a combination research center, educational display and venom extraction laboratory. The venoms extracted were made available for medical research at Leipzig University.

Herpetology at the Arizona-Sonora Desert Museum

JANICE PERRY JOHNSON
Arizona-Sonora Desert Museum, 2021 North Kinney Road
Tucson, Arizona 85745, USA
jjohnson@desertmuseum.org

The humble beginnings of the Arizona-Sonora Desert Museum (ASDM) originated with the visions of William Carr and Arthur Pack. Modeled after Bear Mountain State Park in New York, the Arizona Desert Trailside Museum, as it was originally named, was formally approved by the Pima County Board of Supervisors in March of 1952. Carr's appeal to the board stated his desires for this new museum: "…To establish Tucson Mountain Park and the buildings known collectively as 'The Mountain House' as a leading educational center for the purpose of acquainting the public with their rich but vanishing heritage in wildlife, plant life and scenic values, to the end that, through knowledge, will come appreciation and a better attitude toward all resource conservation …" (Carr 1982). The museum opened Labor Day weekend 1952. A binational institution focusing on the plants, animals, geology, and people of the Sonoran Desert, ASDM flies the national flags of Mexico and the United States at the entrance to illustrate the concept that the Sonoran Desert knows no political boundaries.

Facilities.—The original 'Mountain House' buildings, built and funded by the federal government's Civilian Conservation Corps and Works Progress Administration during the 1930's, consisted of a main building, a small house and a stable. By 1952, these buildings, formerly used for overnight camping by church groups and scout troops, had become termite ridden and dilapidated. Prior to opening day, the lounge of the 'Mountain House' was repaired and became the small animal exhibit room. It is still home to the main reptile exhibit area, although reptile and amphibian exhibits are found throughout the grounds. The original wooden, top-opening exhibit enclosures that were hurriedly built during the five months prior to the grand opening continue to house exhibit specimens to this day. For many years, adjoining areas to the main exhibit hall served as reserve holding for reptiles and invertebrates.

Since 1952 numerous new reptile and amphibian exhibits have been added. In 1953 fiberglass dioramas were incorporated into the small animal exhibit room. These dioramas depict Sonoran Desert scenes and include innovative burrows for bi-level viewing of the enclosure residents. These large dioramas sit on wheeled dollies and can be pulled away from the wall for servicing. Additionally, the hinged lobby wall can be opened to allow the diorama to be wheeled outside for extensive cleaning.

Opening in 1957, a 46-m long exhibit area, called "The Tunnel," allowed visitors to walk along an underground path to view "where the animals go when it gets too hot to be outside." Visitors

could peer at rattlesnakes face-to-face as the ophidians sought shelter in packrat middens. The tunnel closed in 1978, reopening after renovations were completed in 1989.

Unheard of in 1958, because amphibians were rarely exhibited in zoos, an amphibian room opened in another of the 1930s-era Mountain House buildings. Utilizing the best in museum and zoo exposition techniques, a variety of toads, frogs, and salamanders resided in beautiful dioramas, with painted backdrops, constantly circulating water and simulated rocks and plants. The four large amphibian dioramas represent different Sonoran Desert aquatic environments: temporary rain pool, permanent pond, Mexican river and canyon stream. Always pushing the innovation envelope, these unique, glass-fronted dioramas sit on fixed bases and have hydraulically controlled walls. To service an enclosure, a flip of a switch raises the entire semi-circular back of the diorama!

In addition to the above exhibit halls, there are several large outdoor reptile enclosures. One such enclosure houses the Desert Tortoise (*Gopherus agassizi*). Another enclosure, the showpiece exhibit at the museum's front entrance, contains several native lizard species. The lizards are quite active and provide ample opportunity for interpreting lizard behavior to the visiting public. They readily breed in this enclosure.

In the early 1990s a new master plan was created. This plan focused on representing the different habitats within the Sonoran Desert. The first of these habitats opened in 1992 and illustrates a desert grassland. While there are cages for prairie dogs and burrowing owls, the bulk of the enclosures house reptiles and amphibians, including: Mojave Rattlesnake (*Crotalus scutulatus*), Prairie Rattlesnake (*C. viridis viridis*), Desert Massasauga (*Sistrurus catenatus edwardsi*), Common Kingsnake (*Lampropeltis getula*), Desert Box Turtle (*Terrapene ornata luteola*), Tiger Salamander (*Ambystoma tigrinum*), and Green Toad (*Bufo debilis*).

Through a generous donation from the Olsen family, in memory of their son Glenn Charles Olsen, an off-exhibit facility was built in 1998 to house reptiles, amphibians, fish, and invertebrates. This modern facility has rooms along the eastern wall equipped with ultraviolet penetrating glass to provide ultraviolight light for the animals (Fig. 1). It also has a quarantine wing with separate air ventilation for each room. The Olsen building has ample room for holding reserve exhibit specimens and is spacious enough for breeding groups of animals as well as the accommodation of small research projects. Behind the Olsen building are numerous, large breeding enclosures for species such as Tarahumara Frog (*Rana tarahumarae*), San Esteban Chuckwalla (*Sauromalus varius*), and horned lizards (*Phrynosoma* spp.).

With a planned opening in Fall 2006, "Life-on-the-Rocks" will focus on the plants and animals of the Arizona Upland subdivision of the Sonoran Desert. Several large enclosures in this exhibit are outdoor, open-air enclosures with glass fronts. A few species to look for include, but are not limited to: Western Diamondbacked Rattlesnake (*Crotalus atrox*), Tiger Rattlesnake (*C. tigris*), Black-tailed Rattlesnake (*C. molossus),* and Western Lyresnake (*Trimorphodon biscutatus*). One large enclosure will have Gila Monster (*Heloderma suspectum*), Coachwhip (*Masticophis flagellum*), and Gophersnake (*Pituophis catenifer*).

Animal collection.—Animal records dating back to ASDM's first few years are scant. Carr (1982) stated that of the 35 animals exhibited on opening day, it was heavy on the side of reptiles. By

FIG. 1. Reptile holding room in Olsen Building, 2005.

ASDM's second anniversary, 80 reptiles were on exhibit. In the early years Chuck Lowe, Merv Larson, and Bill Woodin were responsible for collecting many of the reptiles, and donations from the public were widely accepted as well. For an institution focusing on the Sonoran Desert, it is odd that historical records show the following animals entered the collection at one time or another: Lance-headed Rattlesnake (*Crotalus polystictus*), Copperhead (*Agkistrodon contortrix*), Texas Tortoise (*Gopherus berlandieri*), and American Alligator (*Alligator mississippiensis*). It is unknown what became of these specimens. Several ASDM specimens may represent longevity records. One wild-caught Filetailed Snake (*Sonora aemula*) lived nearly 17 years, a wild-caught Mexican Rosy Boa (*Lichanura trivirgata trivirgata*) lived slightly over 33 years, and a wild-caught Western Green Toad (*Bufo debilis insidior*) lived 17 years. One captive born Sinaloan Milksnake (*Lampropeltis triangulum sinaloae*) lived for 30 years. Over the years the collection has grown from 97 reptiles and 13 amphibians in 1959 to its current size of 81 reptile species (464 specimens) and 21 amphibian species (112 specimens).

Because of constraints placed on the disposition of surplus animals by both the American Zoo and Aquarium Association (AZA) and the Arizona Game and Fish Department (AGFD), the ASDM staff only attempts to reproduce species where there is a demand for the offspring. In 1958 ASDM had the first known captive reproduction of a "coral kingsnake" (presumably a Sonoran Mountain Kingsnake, *Lampropeltis pyromelana*). In 1981, a reproduction program was initiated for the insular chuckwallas found in the Sea of Cortez, with a primary focus on the San Esteban Chuckwalla (*Sauromalus varius)* resulting in over 200 hatchlings. Although some hatchlings did not survive for long, many were sent out on loan to other institutions. Since 1990, ASDM has had reproductive success with several rattlesnakes including: Western Twin-spotted Rattlesnake (*Crotalus p. pricei*), Banded Rock Rattlesnake (*Crotalus lepidus klauberi*), Northern Black-tailed Rattlesnake (*Crotalus m. molossus*), and Arizona Black Rattlesnake (*Crotalus viridis cerberus*).

Staff.—Stewart Thomas served as Curator of the Small Animal Department (SAD) in 1959, leaving two years later for college. Hired, at the age of 17, to care for the fish, arachnids, and reptiles, Merritt Keasey was ASDM's youngest employee during its first year of operation (Fig. 2). Keasey left ASDM in 1954 to work at Cobra Gardens in New Mexico, returning after Thomas' departure to become ASDM's SAD Curator until retiring in 1979. Serving as Keasey's assistant, Steve Prchal worked from 1970 until 1985, when he resigned to run Sonoran Arthropod Studies Institute (SASI). Arriving in 1980, Howard Lawler, previously of Knoxville Zoo and Zoo Atlanta, took over as Curator of SAD. Lawler was instrumental in establishing accurate record keeping policies, as well as initiating captive breeding programs with insular chuckwalla species. Lawler departed the museum in 1996. Hugh McCrystal, a former keeper at the Bronx Zoo, arrived in 1985 for the position of Keeper Supervisor. When Prchal left the museum, McCrystal accepted the position of Assistant Curator. Upon McCrystal's departure from the museum in 1991, Craig Ivanyi took over as Assistant Curator. At Lawler's parting, Ivanyi became departmental curator. In 1997, the ichthyology and invertebrate zoology portion of the department became a separate department, rejoining herpetology in 2002, when the department was renamed Herpetology, Ichthyology and Invertebrate Zoology (HIIZ). As HIIZ Curator, Ivanyi has been instrumental in establishing numerous departmental research projects and collaborative projects with outside institutions. Currently, Ivanyi serves as both HIIZ Curator and General Curator for the entire museum.

The current HIIZ staff is composed of five highly trained keepers coming to ASDM from many other zoological institutions. They are: Warren (Ken) Wintin (Jacksonville and Knoxville Zoos), Renée Lizotte (Columbus Zoo), Janice Johnson (Dallas and Audubon Zoos), Bill Altimari (Philadelphia Zoo), and Stéphane Poulin (Ecomuseum, Montreal, Canada). ASDM does not have a staff veterinarian. However, the contract veterinarian for the herpetological collection, since 1979, is Dr. James Jarchow. Prior to veterinary school, Jarchow worked as a herpetology keeper under Louis Pistoia at the Columbus Zoo.

Although venomous reptile bites are rare in zoological institutions, ASDM has had two venomous reptile bites in its history. The first bite, in September 1953, was from a Gila Monster (*Heloderma suspectum*). The victim reported that he sat down, applied suction and liberal amounts of ice to the bite site, and took copious notes on the bite's symptoms. The second bite, in June 1994, was from an Arizona Black Rattlesnake (*Crotalus viridis cerberus*). Suction was applied to the bite site and the victim was transported to the nearest hospital. Neither bite had any long-term effects other than acute embarrassment on the victim's part.

Programs.—As a service to the Arizona Game and Fish Department, ASDM coordinates a "Tortoise Adoption Program" for southern Arizona. This program focuses only on the Desert Box Turtle (*Terrapene ornata luteola*) and the Desert Tortoise (*Gopherus agassizi*). Protected in 1989, it is illegal to collect Desert Tortoises. However, there are many "grandfathered" (pre-legislation exemption) tortoises in captivity born to "grandfathered" tortoises which need homes. To this end ASDM assists with the transfer of these unwanted or surplus captive tortoises to qualified private custodians. The tortoises remain the property of the State of Arizona.

In 1998, as an across-the-border educational outreach, Poulin and Ivanyi worked with the Seri Indians of Sonora, Mexico, to build an enclosure for San Esteban Chuckwallas in their native village of Punta Chueca in Sonora, Mexico. The enclosure assists the Seri in teaching their children about their cultural history as well as to encourage ecotourism in their impoverished village. The enclosure has been quite successful for breeding chuckwallas, however it is not known whether it has attracted visitors to their village.

FIG. 2. Merritt Keasey with Gila Monster, circa 1975.

As stated earlier, education has always been a primary focus of ASDM. While many of the early education programs focused on the desert and its inhabitants at large, reptiles were frequently represented. The first of these early educational outreach programs was a television show, *Desert Trails*, which first aired in 1953. This show, hosted by ASDM employee Hal Gras, featured residents of the Sonoran Desert, many of them reptiles, and continued until 1985. For several decades Gras, and his Desert Ark, made frequent visits to local classrooms. He was instrumental in introducing generations of Tucson school children to reptiles. To this day, the name Hal Gras is synonymous with the desert museum among native Tucsonans. For many years a weekly column in the Tucson newspaper featured ASDM mascot George L. MountainLion, Research Associate in Human Behavior. Readers could write to George asking questions concerning the desert and its inhabitants. His column, simple and straightforward, was initially ghost written by Carr, with the task taken on by other staff as time went by.

FIG. 3. Janice Johnson giving "Live and *sort of* on the Loose" presentation, 2005.

In keeping with its education focus, the HIIZ department takes rattlesnakes and gila monsters, as well as arthropods, on the road to many different venues. Most notable of these is the yearly safety day at Fort Huachuca Military Base. Tens of thousands of army personnel get a close up view of the rattlesnakes occurring on the base.

On Labor Day weekend in 2003, the exciting new daily venomous reptile presentation "Live and *sort of* on the Loose" (LOTL) made its debut (Fig. 3). This hour long presentation gives ASDM visitors a close-up view of venomous reptiles supplemented with a lecture about their biology, natural history, venom, and snakebite. This sometimes humorous, sometimes serious, show features a helodermatid (either Gila Monster or Beaded Lizard) and two rattlesnake species. LOTL is extremely popular, with over 200 attendees daily during peak season.

Publications.—ASDM administers three AZA North American Regional Studbooks. Janice Johnson and Craig Ivanyi are co-studbook keepers for the Mexican Beaded Lizard (*Heloderma horridum*). Janice Johnson is also the studbook keeper for the Arizona Ridge-nosed Rattlesnake (*Crotalus willardi willardi*). Stéphane Poulin is the studbook keeper for the San Esteban Chuckwalla (*Sauromalus varius*). The Bibliography details much of the staff-authored publications in recent years.

Research.—The natural desert setting at ASDM is home to several rattlesnake species. The public and staff encounter rattlesnakes every year on grounds, with 25 rattlesnakes encountered on grounds during the first year of operation. Luckily no guest has been bitten while visiting, including those visitors who actually stepped on rattlesnakes! When the public encounters rattlesnakes on the paths HIIZ staff frequently hear comments about our 'loose snakes' or, as a visitor once stated, " . . . that rattlesnake on the walk. It looked just as if it were real!" (Carr 1982). Whenever a rattlesnake is spotted on the grounds, staff members remove the snake. Records dating back to 1967 show rattlesnakes were identified by species and capture date prior to being moved out of harm's way. In 1991, a more thorough study was initiated where all rattlesnakes are identified, sexed, measured, and marked with a unique identification number. Techniques for marking the snakes varied over the years from scale clipping in the early years, to inserting PIT-tags in later years. All Western Diamond-backed Rattlesnakes and Mojave Rattlesnakes have their tail band patterns photocopied. For quick visual recognition, all rattlesnakes initially have the three anterior rattle segments painted with their unique ID number according to a color-coded system, whereby each color represents a number (0–9). This also provides information about shedding frequency as the painted segments move down the rattle with each successive shed, necessitating repainting the ID number on occasion. Capture location and date are recorded prior to release at a designated release area. Release sites varied over the years. Early in the study, release sites ranged from on property in non-public areas to 3.5 km away from grounds. Current protocol divides the grounds into four quadrants. When a rattlesnake is found in one quadrant, it is released in non-public areas within the same quadrant. Since 1991, the four species encountered are: Western Diamond-backed Rattlesnake (*Crotalus atrox*), Tiger Rattlesnake (*C. tigris*), Black-tailed Rattlesnake (*C. molossus*), and Mojave Rattlesnake (*C. scutulatus*). Snake-human contacts on grounds have numbered as high as 177 encounters a year by visitors and staff, with some individual snakes captured 35 times over the years (Fig. 4). Snakes originally captured in 1994 are still encountered. In 2005, several male *C. atrox* were fitted with radio transmitters and are tracked several times a week. Radio implanted snakes move on and off grounds at their own discretion with the most movement seen during the warmer months of the year. They have been observed out in the open, basking on winter days.

Another research project involves an introduced population of Spiny-tailed Iguanas (*Ctenosaura hemilopha*) on ASDM grounds. During the mid 1970s, staff released approximately seven lizards at the bighorn sheep exhibit. Since 1998, a volunteer staff of trained 'lizard-watchers' walk the grounds and areas adjoining the grounds, several times a week to identify all native lizards and Spiny-tailed Iguanas they encounter. These volunteers document all lizards observed on-and-off grounds. Blood for genetic analysis was also taken from several iguanas. This study is intended to demonstrate whether or not the lizards have become established into the surrounding desert, as well as determine the relatedness of the population. The lizard watchers have noted approximately 30 *C. hemilopha* currently living on grounds, however, none has been observed roaming significant distances off grounds.

The ASDM is involved with a conservation project on

FIG. 4. Stéphane Poulin and crowd around wild Western Diamondback Rattlesnake, 2005.

Tarahumara Frogs (*Rana tarahumarae*), a species extirpated from Arizona in the early 1980s. As part of a multi-agency reintroduction program begun in 1992, ASDM was critical in hatching egg masses brought from Mexico, raising them to adulthood, and subsequently breeding the adult frogs. In spring 2005 tadpoles, froglets and adult frogs raised at ASDM were released into the Santa Rita Mountains of southern Arizona. Observations the following year at the same time indicate the introduced population survived the horrific Florida fire that burned 23,183 acres in the Santa Rita Mountains during July 2005 and the anurans appear to be reproducing.

In conjunction with the beaded lizard studbook, Johnson and Ivanyi have been assisting Dr. Michael Forstner, of Southwest Texas University, in a genetic analysis to determine the subspecific status of the captive beaded lizard population. Initial results have been surprising, with *Heloderma horridum* subspecies showing a greater genetic diversity than *Cyclura* species.

The HIIZ staff assists with outside research requests when feasible. We have supplied *Crotalus* and *Heloderma* venom, as well as blood and shed skins for genetic research.

Acknowledgments.—I thank Peggy Larson for her stories about the early days of the desert museum and her assistance in locating historical photographs. Thanks also go to Craig Ivanyi for compiling a list of staff members and employment dates. Finally, I am grateful to the herpetology staff for providing the recent photos accompanying the article.

Editorial Linguistic Deficiency Causes a Superfluous Nomen Nudum in the Gekkonid Genus *Ptyodactylus* (Squamata: Gekkonidae)

WOLFGANG BÖHME
Zoologisches Forschungsmuseum Alexander Koenig
Adenauerallee 160, D-53113 Bonn, Germany
e-mail: w.boehme.zfmk@uni-bonn.de

In his "Gekkotan lizard taxonomy" Kluge (2001) listed not only all species names of gekkotan lizards but also included an alphabetical listing of all the authors of these names. Recently, I happened across the citation of Leptien (1996:20) as the author of *Ptyodactylus keinerlei*, which was considered a nomem nudum referring to *Ptyodactylus hasselquistii* Donndorff, 1798 (Kluge 2001:124). The cross-reference (Kluge 2001:54) reads: "*keinerlei* [n.n.] Leptien 1996 (see *Ptyodactylus hasselquistii* Donndorff, 1798)."

I was surprised by this obviously invalid species description because I have long known Rolf Leptien as an expert of lizards of Africa and the Middle East. Moreover, the name "*keinerlei*" is a German word meaning "not of any sort, not any." Because I could not imagine Rolf Leptien applying such a strange and senseless name, I referred to his 1996 article (which deals with the natural history and husbandry of Arabian leaf-toed geckos, genus *Asaccus*) and found the sentence: "... no difficulties arose when the *A. elisae* were housed in terraria with the larger *Ptyodactylus keinerlei*" (p. 20). Still, no sense emerged from this sentence upon which I asked the author directly. He was absolutely surprised because he was never told by the respective journal (*Dactylus*, now defunct, but then published by the International Gecko Society) that this article had been published. It was in 1994 that he had submitted a short report on *Asaccus* in the United Arab Emirates. He was told by the editor that he could submit a manuscript written in German because it would be translated into English by the journal's staff. The original German version of the respective sentence reads: "Terrarienversuche ergaben, dass sie sich auch mit dem im gleichen Biotop lebenden, größeren *Ptyodactylus hasselquistii* ausgezeichnet vertragen, auch hier kam es zu **keinerlei** Aggressionen." The correct translation is: "Terrarium experiments revealed that they were excellently sociable with the syntopic, larger *Ptyodactylus hasselquistii*; also here, **not any** aggression occurred."

This brief note aims (1) to clarify the origin of the presumed species name "*keinerlei*," (2) to note that it was not Rolf Leptien's fault to have become the involuntary author of a new albeit invalid gekkonid name, and (3) to emphasize that pet journals like *Dactylus* should maintain minimum editorial standards when handling scientific names.

Breeding Behavior of the Cane Toad *Bufo marinus* (Bufonidae): A Successfully Invasive Species

FERNANDO VARGAS-SALINAS*
Department of Biology, University of Puerto Rico
Rio Piedras Campus, San Juan, Puerto Rico

**Correspondence: Cra. 11d # 49-25 Cali, Colombia*
e-mail: vargassalinasf@yahoo.com

Habitat destruction and invasive species are the most important threats to native biodiversity. However, invasive species also provide one of the few opportunities to see population establishment in nature. Thus, the study of ecological and behavioral characteristics of invasive species can provide useful information for increasing the effectiveness of control strategies while also providing an opportunity to study basic aspects of population and evolutionary biology (Sakai et al. 2001).

The Cane Toad, *Bufo marinus* (Amphibia: Anura: Bufonidae), has been introduced in several countries around the tropics for the control of insect plagues in agriculture yet has resulted in negative impacts to native fauna (Lever 2001). For example, native populations of snakes and birds in Australia have declined or disappeared following the expansion of *B. marinus*. These predators are possibly being poisoned when they prey upon this introduced toad (Lever 2001, 2003). However, *B. marinus* also offers an excellent opportunity for understanding the population and evolutionary dynamics of invasive species. This is due to: 1) the history of *B. marinus* invasions is known (date, number, and origin of

individuals introduced; Easteal 1981; Lever 2001); 2) aspects of its natural history and demography have been studied both in native and introduced populations (e.g. Lever 2001; Zug and Zug 1979); and 3) *B. marinus* is relatively abundant and easy to see, catch, and mark for monitoring.

Knowledge of the breeding behavior of *B. marinus* is largely anecdotal (except see Lee 2001; Lee and Corrales 2002). These accounts lack information on sex ratio in breeding aggregations, mating patterns, and female mate selection. Understanding these aspects is important because they affect the direction and strength of sexual selection, including the quality/quantity of offspring produced, genetic variation, population growth rate, and evolutionary dynamics of populations (Blumstein 1998; Caro 1998; Parker and Waite 1997). I studied an invasive population of *B. marinus* in a permanent pond located in northwestern Puerto Rico, West Indies. My aims were: 1) describe the breeding behaviors of males and females; 2) investigate potential mating patterns; and 3) assess relationships between toad body size and clutch size and fertilization success.

Materials and Methods.—I conducted the study in a permanent pond located in the municipality of Quebradillas, northwestern Puerto Rico (18º25.113'N; 66º54.266'W). The pond was in a grassy area, but bordered by a 4–6 m margin of high-density shrubs. Only in the southern part of the pond was the shrub margin wider (up to 20 m), where it connected to a farm with diverse second growth trees. The size of the pond varied with rainfall from <100 m^2 to >500 m^2. When the pond was small, there was a mud bank between the water's edge and the shrubs. When the pond size increased, the mud bank was submerged and the water extended several meters into the shrubs. The mean precipitation in the study area is >1500 mm/year, with the highest rainfall occurring in April–May and August–November.

From March 2003 to April 2004, except in January and February 2004, I made one or two visits per month to the study area to assess breeding activity. I also assessed breeding in May and August 2004. During wet seasons, I monitored rainfall in the study area through the web page <www.wunderground.com>. When there was heavy rain (radar reflectivity > 40 dBZ; estimates of rainfall > 75 mm/h; see web page for details), I went to the study area. During site visits I looked for breeding events (males in the pond, arriving females) and made behavioral observations.

During nights with breeding events, I first divided the pond into eight sections of similar shore length. These sections were useful to record abundance of males around the pond, and location of mating pairs and oviposition. Because the pond size was variable, those sections were redetermined on each breeding event by using several points of reference with known distances. Second, I walked along the shoreline of the pond recording a visual count of the number of individuals per pond section. Third, I caught cane toads, marked them by toe clipping, measured snout-vent length (SVL), recorded sex, and released them in pond section of capture. Lastly, I made behavioral observation for the remainder of the night.

I made behavioral observations from static points and from walks around the pond (2–4 per hour). It was possible to see most breeding individuals from any place in the shoreline of the pond. Because *B. marinus* is a large toad and its eyes turn red and conspicuous with the headlamp light, it was easy to observe individuals swimming, calling, and clasping. I captured pairs to establish their identity and sizes for mating pattern assessments.

I investigated two potential mating patterns, size-dependent mating and size assortative mating (Arak 1983), and spatial patterns of breeding toads among pond sections. First, I examined size-dependent mating by comparing the number of mating and non-mating males between small and large SVL categories per breeding event using a Fisher exact test. Small and large male size categories were determined using the median SVL of all males per breeding event as a cutoff point between small and large. While a greater number of male SVL categories can give more accurate results (Sullivan 1983), few females arriving to mate in each breeding event supported the use of two categories in my study. Second, I examined size-assortative mating by SVL with a Spearman correlation. To see if males aggregated in certain pond sections during breeding, the spatial distribution of males (number of calling and non-calling males) around the pond was analyzed per breeding event using chi-square test. Similarly, to examine whether pairs in amplexus or clutches were aggregated, the numbers of pairs and oviposition episodes in each pond section were analyzed with chi-square tests, pooling the records of all breeding events.

Toad SVL also was examined relative to clutch size and fertilization rate. To examine for a relationship between female SVL and number of eggs oviposited, clutch sizes were counted from six mating pairs collected in a breeding event and put inside containers (45 × 44 × 42 cm of high) with 18 L of water, and regression analysis was conducted. I assessed fertilization rate of mating pairs observed in oviposition in the pond by recording the identity and SVL of mating pairs and flagging their oviposition location. Eggs of each pair were allowed to develop for 24–36 h. Then, I recorded the number of embryos and the number of non-fertilized eggs in a random sample of ± 1000 eggs per clutch. Regression was used to assess relationships between the ratio of male to female SVL and fertilization success, and male SVL and fertilization success. All analyses followed Sokal and Rohlf (1981) and Zar (1999), using STATISTICA (StatSoft Inc., 2000; available at <http://www.statsoft.com> and Statistix (Analytical Software, 1996; available at <http://www.statistix.com>).

Results.—I recorded six breeding events (Table 1); each lasted only one night and occurred after heavy rains, especially at the beginning of wet seasons (March–May and August). Males were abundant during breeding events (23–52 individuals), but on other nights none or very few (1–7 males) were observed around the pond. Females were only present during breeding (Table 1), however on 16 September 2003, I recorded one pair (SVL male: 100 mm, SVL female: 134 mm). There was no evidence (heavy rains, clutches, tadpole congregations) suggesting I missed a breeding event during the period of study. During breeding events, males were observed for the first time from 1900 h, while females were observed from 2000–2330 h, with most of them in amplexus. The breeding event sex ratio was male biased (3.25 to 11.5, Table 1). One male (SVL = 120 mm) mated twice but not in a same breeding event (events 24 and 31 August 2003), and one female (SVL = 129 mm) mated twice (events 24 August 2003 and 20 April 2004).

Males exhibited behavioral plasticity between breeding events (Table 1). When the pond was small (~100 m^2), with a mud bank between the water's edge and the shrub vegetation, the males exhibited scramble competition. Males actively searched for mates, either swimming or jumping on the mud bank. Males seemed to

TABLE 1. *Bufo marinus* breeding events observed in Puerto Rico, West Indies. Each breeding event lasted one night.

Date	Pond size (m^2)	Male behavior	No. males	Mean male SVL ± SD (mm)	No. females	Mean female SVL ± SD (mm)	Male distribution around pond
9 March 2003	~170	Chorus	39	113.4 ± 7.52	8	127.6 ± 8.90	$\chi^2 = 25.6$; P < 0.01
24 August 2003	~100	Scramble	43	113.5 ± 7.86	7	122.0 ± 14.78	$\chi^2 = 6.30$; P < 0.50
31 August 2003	~190	Chorus	40	114.7 ± 7.92	8	135.5 ± 14.10	$\chi^2 = 11.8$; P < 0.10
20 April 2004	~220	Chorus	35	115.4 ± 8.84	5	132.8 ± 5.97	$\chi^2 = 12.30$; P < 0.09
7 May 2004	~160	Chorus	23	114.9 ± 7.91	2	132.5 ± 0.71	$\chi^2 = 12.11$; P < 0.10

be alert to any movement or vibration source close to them. When unpaired males detected a movement, they usually jumped or swam vigorously and attempted to clasp its source. Males clasped tree trunks, mud monticules, turtles, a dead female bullfrog (*Rana catesbeiana*) and swam to clasp birds on the water surface. The interaction between males was frequent, but clasping quickly ended when the male being clasped gave a release call. I conducted several tests which consisted of hitting the ground, moving the water and/or touching the males with my hand and several inanimate objects; males reacted quickly to approach and clasp. Occasionally, a few males (up to 6) gave advertisement calls from the edge of the pond, but only for a few minutes before stopping. During these scramble competition breeding events, the number of males per pond section followed a random pattern (Table 1).

Females arriving at the pond during scramble competition were detected and clasped as soon as they entered the water. I observed several males (up to 5) struggling for the possession of a female and those females trying to move away from the pond (Fig. 1). Unpaired males often tried to dislodge an amplectant male, but most were left behind when the females reached the shrub around the pond. Later, these pairs were immobile among stems and roots of the bank vegetation for the rest of night. The pairs remained among vegetation without going back to water for oviposition until I collected pairs at 0430–0530 h for placement into containers and determination of clutch size counts.

When the pond increased in surface area (>100 m^2), the mud bank was flooded and the water penetrated into the abundant vegetation surrounding the pond. Male searching behavior appeared disrupted by shrub vegetation along this wetted shoreline. Some males (up to 9) formed choruses that persisted for several hours during the night. These calling males were located on mounds of leaves and branches, separated from one another by > 2 m. I did not observe agonistic interactions between males for a calling place. Most males were non-calling; they were floating in the water, but with a tendency to be in the same portion of the pond as calling males (Table 1, nonrandom spatial distribution of males was observed).

The interaction between males was reduced in breeding events with choruses. Males appeared to be much more discriminating about what they clasped; in no case was a male clasping an inanimate object. I conducted the same series of tests with males in these breeding events, but males never responded by clasping objects. The SVL of calling males tended to be larger than that of non-calling males (Table 2). Pairs were observed immobile on the ground or in the water within emergent vegetation; this behavior was contrary to that recorded in scramble breeding events in which the females left the pond rapidly after being clasped. Displacements attempts were rarely seen and were always unsuccessful. Pairs were recorded in oviposition by 0430 h, and most were in the same pond section as the initial pairing record. Overall, there was no particular section of the pond with a disproportionate number of pairs ($\chi^2 = 2.248$; P = 0.938) or clutches ($\chi^2 = 1.579$; P = 0.979).

The scramble behavior and chorus formation were two extremes of a behavioral continuum in male *B. marinus*. An intermediate behavior was recorded on 13 August 2004. During this breeding event, some males formed a chorus (9 males) and others (43 males) were in the water actively searching but without a scramble behavior characterized by frequent male-male interactions and misdirected male clasping of various objects (Table 1). Also, in contrast to the other breeding events with chorus formation, the number of males among pond sections followed a random pattern (Table 1).

Size-dependent mating and size-assortative mating were not observed during any breeding event (Table 3). Large female *B. marinus* produced more eggs than small females (Y = -15390 + 206X; N = 6; r = 8.4; P = 0.023). The ratio of male to females sizes within pairs did not affect fertilization (Y = -0.9011 x + 100.15; R^2 = 0.029; F = 0.42; P = 0.528; Fig. 2a), and male SVL did not affect fertilization rate (Y = -0.0142x + 101; R^2= 0.015; F = 0.22; P = 0.649; Fig. 2b).

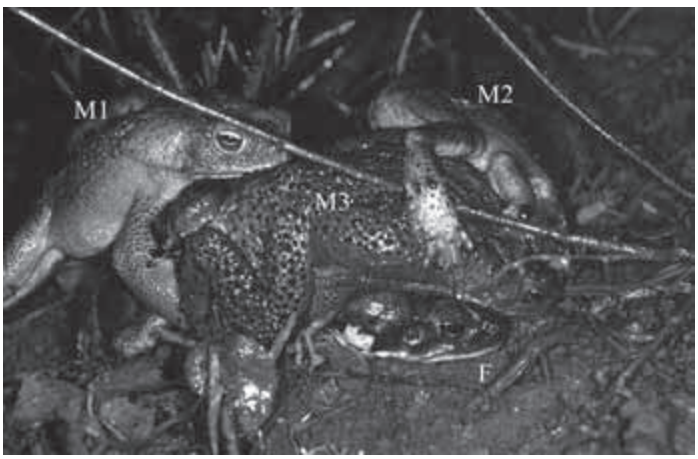

FIG. 1. Mating struggles in *Bufo marinus*. Three males (M1, M2, and M3) compete for a gravid female (F).

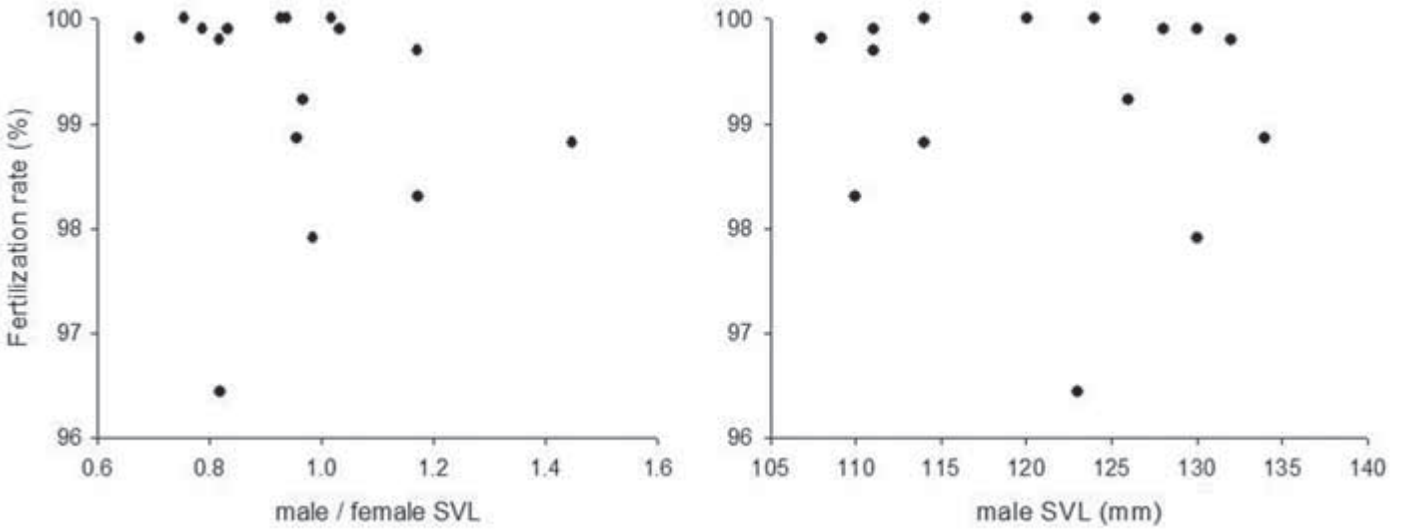

FIG. 2. The ratio of male to female body size (A) and male body size (B) did not appear to affect egg fertilization success in *B. marinus (*N = 16).

Discussion.—In anurans, when the density of males is high and arrival of females is synchronous, the active searching for mates by males appears to be favored (Arak 1983). Under these conditions, the strategy of calling from stationary places may produce very little or no reproductive success because active males intercept females and the advantage of first encountering a female likely outweighs the disadvantage of clasping mistakes (Arak 1983; Wells 1977). Males, however, may change their mating strategies from scramble to chorus formation if they experience a reduction in density (e.g., *Bufo calamita*, Arak 1988a,b; *B. bufo*, Hoglund and Robertson 1987; *B. americanus*, Sullivan 1992; *Rana sylvatica*, Woodbright et al. 1990). In my study, males were not dispersed when the pond increased in size (Table 1). Thus, a reduction in density is not likely the main factor promoting the change in behavior of males in this population; the vegetation around the pond appears to play a more important role. Calling may be favored rather than searching actively among barriers imposed by the vegetation. Other studies also point out the role of vegetation in different aspects of the mating behavior of anurans (Arak 1988a; Gerhardt 1994; Wells and Schwartz 1982).

Explosive breeding in anurans such as *B. marinus* imposes limits to male and female behavior that affect their reproductive success (Emlen and Oring 1977; Sullivan et al. 1995). In explosive breeders, males mate simultaneously. Hence, the rapid acquisition of females is crucial for male reproductive success and it is not expected that male *B. marinus* discriminate among females to further increase their fitness, such as searching for larger females with more eggs (Arak 1983; Wells 1977). Similarly, an abundance of single males actively clasping moving objects likely results in few opportunities for females to select particular males as mates (Sullivan et al. 1995). In summary, time restrictions and male-biased sex ratios during breeding events of *B. marinus* may explain the non-random mating and the non-assortative mating by size I found, and limits the opportunity for a male to mate many times. Also, male-biased breeding congregations promote a strong intra-sexual competition among males, which may promote diverse male mating strategies (Halliday and Tejedo 1995). In *B. marinus*, those strategies were associated with male spatial distribution patterns around the pond: scramble behavior (random distribution), chorus and non-calling males (aggregated distribution).

Displacement of paired males by single males is common in species of the genus *Bufo* and could produce a change from random mating to non-random mating (Lamb 1984, Halliday and Tejedo 1995). According to Lee (2001) and Lee and Corrales (2002), amplexus displacements in *B. marinus* are commonly successful and can produce non-random mating; however, commentaries by Savage (2002) suggest the contrary. Differences in breeding environment may reduce the success of amplexus displacements in *B. marinus* and thus, reduce consequent effects on mating patterns. While my results do not show a large male mating advantage in *B. marinus*, there was a tendency (P = 0.1) for non-random mating in the breeding event with scramble behavior, which is attributed to successful displacement performed by two large males (Vargas 2005a). In contrast, when pond size was large (>100 m^2) females in amplexus appeared to easily avoid intruder males by diving bellow the surface of the water, and moving in the emer-

TABLE 2. Body size, mean SVL ± SD (N), of calling and non-calling male *Bufo marinus* at a pond in Puerto Rico, West Indies. There are no data for the 24 August 2003 breeding event because the males were in scramble competition and calling males were intermittent.

Date	Male SVL (mm)		Student's t-test
	Calling	Non-calling	
9 March 2003	116.4 ± 10.26 (7)	112.8 ± 6.82 (32)	t = 1.149, P = 0.257
24 August 2003	—	—	—
31 August 2003	118.8 ± 6.85 (9)	113.6 ± 7.91 (31)	t = 1.787, P = 0.082
20 April 2004	118.9 ± 8.26 (8)	114.39 ± 8.89 (27)	t = 1.272, P = 0.212
7 May 2004	121.4 ± 9.32 (7)	112.6 ± 6.32 (16)	t = 3.043, P = 0.116
13 August 2004	122.1 ± 8.06 (9)	115.6 ± 8.56 (43)	t = 2.002, P = 0.050

TABLE 3. No size-dependent mating patterns were observed for *Bufo marinus*. There is no analysis for the 7 May 2004 breeding event because only two pairs were recorded.

Date	Median male SVL (mm)	No. small males		No. large males		Size-dependent mating (Fisher Exact test)	Size-assortative mating (Spearman correlation)
		Paired	Unpaired	Paired	Unpaired		
9 March 2003	114	5	10	3	21	P = 0.442	r_s = 0.55; P = 0.159
24 August 2003	112	2	22	5	14	P = 0.121	r_s = 0.04; P = 0.939
31 August 2003	116	4	17	4	15	P = 0.592	r_s = -0.23; P = 0.575
20 April 2004	114	2	16	3	14	P = 0.472	r_s = 0.30; P = 0.624
7 May 2004	113	1	8	1	13	—	—
13 August 2004	115.5	7	19	9	17	P = 0.382	r_s = 0.122; P = 0.651

gent vegetation. Moreover, intruder males appeared to need to lean on a hard substrate to gain sufficient leverage to dislodge the paired male (Vargas 2005a), and that load point was absent in the water.

At oviposition, larger single males may challenge smaller paired males and displace them from females (Davis and Halliday 1977, 1979). It is curious that at 0430 h females started oviposition during breeding events with choruses but not in the breeding event with scramble competition. It is possible that during chorus breeding events females started oviposition earlier because they were hidden among emergent vegetation and were not disturbed by single males. In contrast, in scramble breeding events there was not emergent vegetation for females to use as refuge if they returned to water for oviposition. It is possible that females might delay oviposition until sunrise when single males stopped activity and left the pond (F. Vargas, pers. obs.) and thus avoid risk of suffocation if multiple males were to clasp them. This hypothesis needs further study in *B. marinus* but behavioral plasticity in breeding behavior of females has been recorded in many species (Jennions and Petrie 1997).

When explosive breeders form choruses, females could have more opportunity to express their mating preferences because they are less likely to be intercepted by searching males (Sullivan et al. 1995). In my study, female *B. marinus* could be attracted to or have mating preferences for calling males with particular phenotypes, but as a female approached a calling male, non-calling males in the water had an opportunity to intercept her. However, if a female approached by ground or within emergent vegetation to a calling male, she appeared to reduce the possibility of being intercepted by non-calling males (FV, pers. obs.). From the male's perspective, calling can increase the chance of attracting females, but calling males could be susceptible to predators such as rats (Fitzgerald 1990; FV, pers. obs.). Non-calling males in the water may have a lower risk of predation, but they do not readily attract females. Non-calling males can clasp females they detect but due to the high number of non-calling males the probabilities of mating may be low for each male in the water. A possible difference in the reproductive success between calling and non-calling males is still an unresolved aspect in *B. marinus* (Lever 2001).

Mate choice is expensive, and it is expected that the level of female's selectivity will correspond to the benefits obtained if mated with particular males (Andersson 1994; Grafe 1997). The absence of direct benefits in *B. marinus* such as territories with abundant resources, parental care (Vargas 2005b) and/or differential egg fertilization rate (Fig. 2) does not suggest high selectivity by females. Female *B. marinus* might move to the male that is easiest to find (Arak 1988a; Parker 1983). This behavior may be beneficial if it reduces the risk of predation, disease and/or parasitism, which may be associated with time spent in the water. In many anurans, more time in the pond also increases the risk of dangerous interactions with unpaired males (Arak, op cit.). These take-over attempts imply a cost to females in terms of energy, and also expose them to death by suffocation by the conspecific males (e.g., *B. bufo*, Davis and Halliday 1979). I did not observe this extreme case in *B. marinus* but it cannot be discarded due to the physical constraints multiple male clasping could have on a female (Fig. 1). Also, the hypothesis of beneficial rapid pairing is supported by the random spatial pattern of pairs and clutches around the pond.

Studies of breeding behavior in different populations of a same species under different environmental characteristics are useful for understanding ecological determinants of the breeding behavior, the strength and direction of sexual selection (Sullivan et al. 1995), and the role of reproduction in the population ecology, which is particularly relevant for invasive species. This study shows how characteristics of breeding locations can change in just days or weeks, and affect breeding behavior. Behavioral plasticity may increase adaptability to novel breeding conditions (Sakai et al. 2001), such as those conditions experienced by invading species as they enter new areas. Also, low female selectivity could reduce the strength of the Allee effect (reduction in fitness of individuals in small populations) when few individuals invade new habitats (Blumstein 1988; Møller and Legendre 2001). Lastly, high female fecundity and the high fertilization rate can optimize the recruitment of abundant juveniles with the subsequent positive effect on population growth rate and recovery of genetic variation (Nei et al. 1975). The Cane Toad, *B. marinus*, appears to have all these attributes, contributing to its successful invasion of many tropical areas worldwide.

Acknowledgments.—Special thanks to Richard Thomas, Tugrul Giray, Alberto Sabat, David Bruck for their advice on study design and implementation, and for comments on the manuscript. Robert Jaeger provided editorial help. Deanna H. Olson, Leslie Dyal, and an anonymous reviewer substantially improved first versions of the manuscript. I am grateful to Wilfredo Hernandez Aguiar and Ivan, Irvin and Edsel Igartua Butler for their support and help in the field. Thanks to Claudia Patricia Ruiz, Neftali Rios, Johanna Delgado, Jaime Fuertes, Sherryll Mitchell, Cristina Jimenez, Zaira Rios and Ivania Ceron for their invaluable assistance with both field and lab work. This research was supported by the Graduate Program

in Biology and the Decanato de Estudios Graduados of the University of Puerto Rico, and IdeaWild. The Department of Natural and Environmental Resources of Puerto Rico issued the collection permit (01-IC-084).

Reference Hematology and Serum Chemistry Values for the Diamondback Terrapin (*Malaclemys terrapin)*

RALPH E. WERNER
Richard Stockton College of New Jersey
Pomona, New Jersey 08240, USA
e-mail: ralph.werner@stockton.edu

Health assessment of turtles is important in order to successfully manage wild animal populations and knowledge of hematologic and serum chemistry values for apparently normal wild individuals are an essential part of this evaluation (Jacobson et al. 1999; Werner et al. 2002). Evaluation of blood samples can provide information on red and white blood cell distribution, electrolyte levels, waste products, and selected enzyme activity. An apparently healthy looking turtle could have serious internal disease that would likely be missed without examining a blood profile. In order to accurately evaluate turtle blood samples, a reference range of values must be established for each species. Blood reference values have been established for less than 5% of all known turtle

species (McArthur et al. 2004). The present study was undertaken to establish reference ranges for various blood parameters in the Diamondback Terrapin, *Malaclemys terrapin*. It should be emphasized that the term "reference" is preferred over the mostly obsolete term "normal" since it is virtually impossible to determine whether or not each sampled individual in a wild population is "normal" (Solberg 1994). The goals of the present study were: to establish reference ranges for diamondback terrapin hematology and serum chemistry values, to determine if differences in blood values exist between males and females, to determine if variations exist due to the time of year, and to find out if the blood parameters reported by veterinary clinical pathology laboratories are of any diagnostic value in *M. terrapin*.

Malaclemys terrapin is found in brackish marshes of the eastern and Gulf Coasts of the United States. Although seven subspecies have been identified, this study only looked at the Northern Diamondback Terrapin. Various factors have led to a decline in the numbers of Diamondback Terrapins over the years and conservation efforts are now needed to protect this species. It has been well known as one of the best tasting turtles in the world, which almost led to its extinction at the beginning of the 20th century (Garber 1990a). This turtle is once again resurging as a desirable food delicacy in Asian communities (Garber 1990b). Exhibitors and hobbyists are also attracted to this colorful, intriguing reptile and it often appears in both public and private collections. Oil spills (Burger 1994), heavy metals (Burger 2002), traffic (Wood and Herlands 1993), commercial crabbing (Garber 1990b), predation (Feinberg and Burke 2003) and coastal development have taken their tolls on local diamondback populations. Regulations to protect diamondbacks vary widely among the coastal states and range from limited hunting seasons to designations such as special concern, threatened, or endangered.

An extensive search of the literature uncovered two references for blood values in *Malaclemys terrapin*. One paper examined hemoglobin values in two specimens (Goin and Jackson 1965). The other reference evaluated red blood cell (RBC) counts that were obtained from three animals (Hutchison and Szarski 1965).

Other studies have examined a few parameters of Diamondback Terrapin blood. One paper reported on the percentage of RBCs in blood smears from one individual (Englebert and Young 1970) and another article evaluated changes in hemoglobin and RBC counts for one to six captive terrapins over a one year period (Gilles-Baillien 1973). Changes in sodium, potassium, and urea were noted in three different experiments involving salinity manipulations (Bentley et al. 1967; Dunson 1970; Gilles-Ballien 1970). Serum chemistry reference values for *Malaclemys* are not available.

Materials and Methods.—From June through August of 2003 and May through August of 2004, 103 apparently normal *M. terrapin* were captured, bled, and released in Stone Harbor, New Jersey (ca. 39.05°N, 74.80°W) and Wellfleet (Cape Cod), Massachusetts (ca. 41.90°N, 70.03°W). Salinity at both collection sites was a constant 28–30 parts per thousand (ppt). The sample population consisted of 76 females and 27 males of various sizes (Table 1). In Stone Harbor, all terrapins were captured in baited crab traps that were checked within six hours of being set. The terrapins in the Wellfleet group were caught with hand nets from a kayak. In both locations, the turtles were transported in dry, plastic pails to a laboratory for blood collection and then released the same day or the following morning at the area of capture. Blood samples were obtained from one to fourteen hours following capture. In May 2004, only three terrapins were sampled. For June 2003–2004, 23 blood specimens were obtained while July 2003–2004 produced 33 specimens and August 2003–2004 yielded an additional 44 blood samples. All turtles were examined, weighed, and the carapace length was recorded.

Blood was obtained from the femoral vein using a disposable one milliliter syringe with a 26 gauge 3/8 inch needle. The collection site for blood testing must be carefully selected because of the extensive lymphatic network in turtles (Ottavaini and Tazzi 1977). In a study by Werner and Lindley (2005) on the effects of lymph dilution on blood samples in *Malaclemys*, the femoral vein was found to be the most accessible and reliable collection site for obtaining undiluted blood samples.

Part of the sample was immediately placed into one or two heparinized microhematocrit tube(s). Two drops of blood were used two make two blood smears, and a drop of blood was hemolyzed by vigorous stirring for hemoglobin analysis. The remainder of the sample (ca. 0.3–0.6 ml) was placed in a Microtainer® lithium separator tube and immediately spun down in a Statspin RP® centrifuge. Only one sample was hemolyzed and it was discarded. All samples were immediately refrigerated and remained that way until processed.

A commercial laboratory (Antech Diagnostics, 1111 Marcus Avenue, Lake Success, New York 11042, USA) did white blood cell counts (WBC) from blood smears, hematocrits, and serum chemistries, which included glucose, serum urea nitrogen (SUN), total protein (TP), albumin, aspartate aminotransferase (AST), calcium, phosphorous, sodium, potassium, chloride, globulin, creatine phosphokinase (CPK), and uric acid (UA). This panel of tests is offered by Antech as a Comprehensive Reptilian Profile. Hemoglobin was measured by the author utilizing a BMS® hemoglobinometer.

Means, medians, standard deviations, ranges, and histograms were calculated for each blood value. The only subset analyses performed were male versus female and time of the collecting season. The males and females were compared by two-tailed t-tests ($\alpha = 0.05$). The blood values were tested for correlations with collection date (Spearman Rank Correlation test).

Results.—Of the total 103 terrapins sampled there was not always enough blood to perform all tests on each individual. There were 56 serum chemistries, 61 hematocrits, 87 white blood cell (WBC) counts, and 85 hemoglobins that made up the final results. The values are given as means, standard deviations, and ranges.

The mean hematocrit value for 61 samples was 31.8% ± 7.5.

TABLE 1. Size data for male (M) and female (F) *Malaclemys terrapin* from New Jersey (NJ) and Cape Cod (CC).

Sex	Site	Carapace L (cm)			Weight (gm)		
		mean	median	range	mean	median	range
M (N = 26)	NJ	10.8	10.7	8–13	216	216	114–351
M (N = 1)	CC	10.9			218		
F (N = 60)	NJ	15.6	13.1	9.8–19.8	537	369	166–1600
F (N = 16)	CC	17.3	17.4	13.2–21	851	885	349–1705

The range was from 15–55%. Hemoglobin concentration averaged 9.6 g/dL ± 1.1 with a range of 7–11.7 g/dL. The WBC counts for 87 terrapins had a mean of 11.3 × 10^3/μL ± 4.5 and a range of 3.5–28 ×10^3/μL (Table 2). Males (N = 21) had significantly higher WBC values (P < 0.05) with an average of 13.9 × 10^3 /μL ± 4.8. Female (N = 66) WBC values had a mean of 11.3 × 10^3/μ/L ± 4.5 (Table 3). The predominant WBC was the heterophil (74.6%). The next most common cell type was the lymphocyte (17.7%). Azurophils averaged 3.8% and the mean for monocytes was 2.3% (Table 2).

Serum chemistry values for 56 terrapins are tabulated in Table 4. Analysis of male (N = 8) and female (N = 48) values using a two tailed t-test revealed that males had significantly lower (P < 0.05) calcium, phosphorous, chloride, total protein, and albumin levels than females (Table 3). A significant positive correlation (values increased as the season progressed) was demonstrated for SUN and CPK, while a negative correlation was seen for both calcium and phosphorous.

Discussion.—Establishing reference blood and serum chemistry values for a species presents several problems. Reptiles do not precisely regulate serum constituents as do mammals so results from free living reptiles must be evaluated in light of age, reproductive status, environment, and overall condition (Mautino and Page 1993). The data presented here were obtained from 76 female and 27 male wild Diamondback Terrapins. One reason for this sex disparity is that obtaining femoral vein blood from smaller specimens, which were mostly males, was often unsuccessful. In *M. terrapin* the femoral vein is not visible so venipuncture was "blind" and, at times, unproductive. The second reason that there were fewer males in the sample group is that in both collecting areas captured females outnumbered males by approximately two to one.

Hematocrit, hemoglobin, and WBC ranges were very similar to published values for other turtle species (Anderson et al. 1997; Dessauer 1970; Dickinson et al. 2002; Frye 1991; Fudge 2000; Gaumer and Goodnight 1957; Marks and Citino 1990; Mader 1996; McArthur et al. 2004; Rosskopf 1982). One exception was a hematologic study of Aldabra Giant Tortoises (*Aldabrachelys gigantea)* where hemoglobin, hematocrit, and WBC means were lower than for most other species (Hart et al. 1991). This disparity was most likely the result of lymph dilution, as previously noted, because blood was taken from the dorsal coccygeal vein and a clear fluid was often noted in the syringe prior to obtaining blood (Hart et al. 1991). No differences were seen in the hematocrits and hemoglobins of males and females nor were there any significant differences as the collecting season progressed as have been reported in some other turtle species (Anderson et al. 1997; Dickinson et al. 2002; Gilles-Baillien 1973; Lawrence and Hawkey 1986; McArthur et al. 2004; Pages et al. 1992). Male *M. terrapin* in this study had higher average WBC numbers than their female counterparts. A similar disparity was noted in Desert Tortoises (*Gopherus agassizii)* (Dickinson et al. 2002). A possible explanation is a more pronounced stress response in captured males but it might also just be due to variation in a small sample size. While azurophils were the third most commonly observed WBC type, their function in turtles in unknown (Christopher et al. 1999) and even their existence in chelonians is clouded (McArthur et al. 2004). Eosinophils and basophils were not found very often and, combined, only made up about 2.7% of the total WBC popula-

TABLE 2. Values for red blood cells (RBC) and white blood cells (WBC) for *Malaclemys terrapin* from New Jersey and Cape Cod. RBC values based on 16 males and 45 females; WBC values based on 21 males and 66 females.

Test	Mean	SD	Range	Units
Hematocrit	31.8	7.6	15–55	%
Hemoglobin	9.6	1.1	7–11.7	g/dL
WBC	11.3	4.5	3.5–28	10^3/μL
Heterophils	74.6	13.4	29–91	%
Lymphocytes	17.7	12.6	4–63	%
Monocytes	2.3	3.0	0–16	%
Eosinophils	1.1	1.9	0–7	%
Basophils	1.6	2.1	0–14	%
Azurophils	3.8	3.5	0–14	%

TABLE 3. Blood and chemistry values significantly different between male and female *Malaclemys terrapin* (P < 0.05).

	Male		Female		
Test	Mean	SD	Mean	SD	Units
WBC	13.9	4.8	10.6	3.9	10^3/μL
Calcium	9.2	1.3	13.6	5.1	mg/dL
Phosphorous	4.1	0.7	5.5	1.7	mg/dL
Chloride	99.7	11.2	108.0	9.1	mEq/L
Total protein	3.6	1.1	4.2	0.7	g/dL
Albumin	1.0	0.3	1.3	0.3	g/dL

TABLE 4. Serum chemistry values for male (N = 8) and female (N = 48) *Malaclemys terrapin* from New Jersey and Cape Cod. Refer to Table 3 for gender differences.

Test	Mean	SD	Range	Units
Glucose	100.9	69.0	10–267	mg/dL
SUN[1]	104.7	54.0	27–258	mg/dL
Uric acid	1.3	0.9	0.3–5.3	mg/dL
TP[2]	4.1	0.8	1.8–5.7	g/dL
Albumin	1.3	0.3	0.4–2	g/dL
Globulin	2.8	0.6	1.4–3.9	g/dL
Calcium	13.0	5.0	6.6–30	mg/dL
Phosphorous	5.3	1.7	2.8–11.1	mg/dL
Sodium	148.7	11.0	120–174	mEq/L
Potassium	4.9	1.0	3.4–7.5	mEq/L
Chloride	106.9	9.7	86–123	mEq/L
AST[3]	218.1	130.1	75–681	U/L

[1]Serum urea nitrogen
[2]Total protein
[3]Aspartate aminotransferase
[4]Creatine phosphokinase

tion. This agrees with other published values for turtles (Anderson et al. 1997; Dickinson et al. 2002; Fudge 2000; Marks and Citino 1990; Mader 1996; Mader 2000; McArthur et al. 2004; Rosskopf 1982).

Serum chemistries in many instances had extremely large ranges. A lack of references on normal *M. terrapin* physiology makes interpretation of these data difficult.

In this study glucose levels fluctuated widely. Frye (1991) summarized glucose concentrations for 12 species of turtles. The average was 65 mg/dL with a range of 33–99 mg/dL. Glucose levels in chelonians do not seem to be related to diet (Anderson 1997) but they might be related to reproductive activity. In *Lissemys punctata,* the Indian Soft-shelled Turtle, fasting glucose values in reproductively active males were 91.4 ± 2.8 mg/dL while in females the glucose values were 119.3 ± 1.7 mg/dL (Chandavar and Naik 2004). The reverse was seen in the Pancake Tortoise (*Malacochersus tornieri*), where glucose levels were reported higher in males than in females (Raphael et al. 1994). In addition, seasonal glucose variations have been shown to occur in turtles from temperate zones (Christopher et al. 1999; McArthur et al. 2004). An experiment with Argentine Sideneck Turtles (*Phrynops hilarii*) found that plasma glucose was not affected by starvation or re-feeding (DaSilva and Migliorini 1990). It seems that glucose levels in chelonians are not well understood (Chandavar and Naik 2004) and therefore are difficult to interpret.

Urea nitrogen levels in this study varied widely. Similar results were found in 30 *Aldabrachelys gigantea* (Ghebremeskel et al. 1991). Raphael et al. (1994) found that urea nitrogen in *M. tornieri* was below the limit of sensitivity of their test method. Other studies have reported SUN values that ranged from <1–80 mg/dL (Anderson et al. 1997; Dickinson et al. 2002; Pages et al. 1992; Rosskopf 1982). A five year study of *G. agassizii* noted that urea nitrogen concentrations were highest when the turtles emerged from hibernation and then decreased significantly (Christopher et al. 1999). The present study showed the opposite—a significant ($P = 0.002$) increase in SUN from June through August. The reason for this increase is unknown. In a study of osmoregulation in *M. terrapin*, urea was found to be one of the major regulators of osmolarity and was likely reabsorbed from the bladder or excreted as the surrounding water salinity changed (Gilles-Ballien 1970). Serum urea nitrogen does not seem to be very useful for assessing renal disease in reptiles and this would seem especially true in *M. terrapin* (Fudge 2000; Mader 1996; McArthur et al. 2004).

The uric acid levels of *M. terrapin* were similar those of eight other species of chelonians (Mader 1996). Uric acid is primarily the end product of protein and purine metabolism, and thus increases following a meal. Uric acid is influenced by other variables precluding its use as an indicator of renal failure in turtles (Fudge 2000; Mader 1996; McArthur et al. 2004).

The mean total protein results in this study are similar to values reported for 13 different turtle species (Frye 1991). I found that albumin was lower in males but globulin levels were the same in both sexes. The reference laboratory (Antech) uses a colorimetric assay for total protein and the bromcresol green dye (BCG) method for albumin determination. Globulin is then calculated as the difference. The BSG method of albumin determination can overestimate this protein due to lack of specificity (Clase et al. 2001; Stokol et al. 2001) so it is possible that albumin values for both sexes are artificially elevated. Dessauer (1974) noted that the highest reptilian protein values are most likely to be found in females during estrous. Estrogen has been shown to increase serum protein levels (Clark 1967) and one study has reported higher TP values in female Gopher Tortoises (*Gopherus polyphemus*) (Taylor and Jacobson 1982). The plasma protein, vitellin, can also alter plasma protein values in egg-producing females (Dessauer 1974). Since most of the blood in the present study was collected during the egg-laying season, it seems probable that the higher TP concentration in females was probably due to albumin and vitellin.

Although sodium concentration was similar for both sexes, chloride values were higher in female *M. terrapin*. Another study noted the same male/female chloride disparity in *Elseya novaeguineae,* the New Guinea Snapping Turtle (Anderson et al. 1997). The sodium, potassium, and chloride values for 14 other turtle species were comparable to this study (Frye 1991). Because these three electrolytes and urea are involved in the regulation of osmolarity in *Malaclemys* their concentrations should increase or decrease as local water salinity increases or decreases (Bentley et al. 1967; Dunson 1970; Gilles-Baillien 1970). Diamondback Terrapins also possess a "salt gland" that helps to rid the body of excess sodium in a saline environment since their kidneys lack the ability to excrete hyperosmotic urine relative to blood plasma (Dunson 1970). In a study by Dunson (1970), sodium averages went from 100.7 mEq/L for terrapins spending a year in fresh water to 154.0 mEq/L for those in sea water. Gilles-Baillien (1970) found similar results. The conclusion is that sodium values (along with potassium, chloride, and urea) must be interpreted in light of environmental salinity. Although the salinity of both collecting sites was similar (28–30 ppt) little is known about the water routes of this species. Preliminary radio telemetry studies at the Stone Harbor collecting site indicate that individual *M. terrapin* travels between areas of varying salinity during the day (pers. obs.).

The sex disparity in chloride may be due to the low number ($N = 8$) of males in this part of the study. Another possibility is that nesting females leaving the water to lay eggs become somewhat dehydrated.

Calcium and phosphorous were both significantly elevated in female *M. terrapin*. The samples collected during this two-year study were during the breeding/nesting season and often were from females that were producing (or had just deposited) eggs. Several other sources have documented increased calcium levels in ovulatory chelonians (Anderson et al. 1997; Christopher et al. 1999; Clark 1967; Dessauer 1970; Dickinson et al. 2002; Fudge 2000; McArthur et al. 2004; Raphael et al. 1994). It was found however that as the season progressed the calcium and phosphorous values declined, which may be the result of continual egg production from June to August.

The two serum enzymes, AST and CPK reported by the diagnostic laboratory are included in their Comprehensive Reptilian Profile. Antech does not provide reference values for either of the two enzymes and they do not seem to be of much diagnostic value. Aspartate aminotransferase (AST) is present in all body tissues so it is not specific for any particular organ (Duncan et al. 1994; Mader 1996). Creatine phosphokinase (CPK) is primarily found in skeletal and cardiac muscle. The average AST values were similar to those observed in pancake tortoises (*M. tornieri*) (Raphael et al. 1994). Aspartate aminotransferase values for Desert Tortoises (*G.*

agassizii) were much lower (Dickinson et al. 2002). The Radiated Tortoise (*T. radiata*) also had relatively low AST values (Marks and Scott 1990). Such a large range and standard deviation of AST and CPK in the present study of apparently healthy Diamondback Terrapins makes interpretation difficult. The highest ten values for AST and CPK were scattered throughout both populations and collection days so specific capture and/or handling techniques did not seem to be a factor. The most likely explanation for the high enzyme values in the Diamondback Terrapin and Pancake Tortoise studies is that probing for a vein with a needle caused tissue trauma and resulted in the release of these two enzymes which in turn contaminated the blood sample (Duncan et al. 1994; McArthur et al. 2004). It is unlikely that the relatively high diamondback values were due to massive muscle (or other tissue) damage since all terrapins appeared healthy at the time of capture and were not obviously injured during handling. The significant (P = 0.03) increase in CPK with the time of year is hard to explain. It would seem that blood collection techniques would improve as the season continued which should lower CPK values.

Stress is reported to cause an increase in heterophils (Fudge 2000) but changes in other blood parameters due to stress are mostly unknown (McArthur et al. 2004). An inspection of the highest ten values for heterophils, glucose, and SUN showed no pattern with regards to collection date or site. This would tend to preclude specific capture, holding, or collection techniques as being responsible for the elevations. It is reasonable to assume that all wild chelonians are under stress when captured, restrained, and sampled for blood and thus all results are going to be "stress" values to some degree.

The reference ranges reported here are for terrapin populations in two areas of the northeastern United States. Blood testing of terrapins throughout their natural range will provide information on any differences that may exist in various geographic locations or subspecies. Finally, examination of blood from diseased diamondbacks may uncover valuable diagnostic markers to aid in assessing health status.

Information on the basic life histories of many species of amphibians is lacking in the literature. This deficiency can hinder comparative studies and contribute to a poor understanding of broad patterns of life-history variation. A striking example of this deficiency is the minimal amount of published information on egg clutch characteristics of *Hyla gratiosa*. Published data for this species consists of an estimate of 2084 eggs from a single clutch collected in 1921 in the Okefenokee Swamp in southern Georgia (Livezey and Wright 1947; Wright 1932). In addition, a study evaluating the influence of time spent in amplexus on oviposition behavior of *H. gratiosa* in northern Florida found an average clutch size of 867.2 (SD = 330.5, N = 11) for females in the longest amplecting group, which were allowed to remain in amplexus for 1.5 h prior to separation (Scarlata and Murphy 2003). Here we report characteristics of egg clutches for *Hyla gratiosa* in two areas in the southeastern United States: Scotland Co., North Carolina and Leon Co., Florida, and evaluate relationships between female body size and clutch size and geographic variation in clutch size. These data contribute to baseline reproductive information for this species and suggest some interesting questions for future studies.

Materials and Methods.—Seventeen clutches were collected from two localities in Leon Co., Florida (FL; 30.375°N, 84.37°W, elevation 7 m and 30.389°N, 84.329°W, elevation 9 m) from April through June 2003, and 13 clutches were collected from Grassy Pond in Scotland Co., North Carolina (NC; 35.009°N, 79.422°W, elevation 80 m, Travis 1983) in 1979. Amplexed pairs were collected, transported to the laboratory, and placed in separate covered buckets filled with well water (FL) or pond water (NC) for oviposition (as described in Gunzburger 2006). The following morning, adult size was measured using wet mass (g) in NC or tibio-fibula length (TFL, in mm) in FL. Number of eggs in each clutch was counted (NC) or photographed in a small container and eggs counted later from the photograph (FL). Diameter of the vitellus of 9–18 eggs from each clutch collected in NC was also measured using a dissecting microscope. Vitellus diameter data are presented, but no analysis was performed, because a small proportion of the eggs in each clutch were measured and variation in vitellus diameter may have arisen due to variation in development time. All analyses were performed for each population separately because the data for the two populations were collected at different time intervals separated by almost 30 years.

TABLE 1. Summary data (± SD, minimum – maximum in parentheses) of clutch characteristics and adult size [tibio-fibula length (TFL, mm) or mass (g)] from two populations of *Hyla gratiosa*. ND indicates no data was collected on that characteristic for that location.

Location	Sampling Interval	N	Clutch Size	Egg Diameter	Female TFL	Female Mass	Male TFL	Male Mass
Scotland Co., North Carolina	1979	13	2826 ± 842 (1825–4381)	1.39 ± 0.10 (1.19–1.55)	ND	14.72 ± 2.40 (11.01–17.28)	ND	15.71 ± 2.60 (13.50–20.28)
Leon Co., Florida	2003	17	1008 ± 249 (459–1492)	ND	22.63 ± 1.01 (21.5–25)	ND	24.00 ± 1.47 (22–26.4)	ND

Results.—Clutch size of *H. gratiosa* ranged from 459–4381, covering a two- to three-fold range even when considered among females from a single location (Table 1). Clutch size was significantly larger in NC than FL (t-test, t = -8.48, P < 0.001, Table 1). For the FL population, TFL of female *H. gratiosa* was significantly smaller than males (t-test, t = -3.13, P = 0.004, Table 1). Female TFL was not strongly correlated with the TFL of the male with which they were in amplexus (Pearson r = -0.08) or clutch size (r = 0.06, Fig. 1). For the NC population, mass was similar in males and females (t-test, t = -1.01, P = 0.32). Female mass was not strongly correlated with mass of the male with which they were in amplexus (Pearson r = -0.06). Larger females produced larger clutches (r = 0.59, Fig. 1). The diameters of individual eggs varied widely among the NC females, with the largest size being 30% larger than the smallest (Table 1).

Discussion.—Clutch size was larger for *H. gratiosa* in NC than in FL; this could be due to larger body sizes in NC (Travis, unpubl. data), temporal changes, or independent geographic variation, all of which are confounded in these collections. The published data on intraspecific geographic variation in body size in anurans suggests a trend toward larger sizes at higher latitude and elevation, but further study is needed to determine if this is the case for *H. gratiosa* (Ashton 2002; Berven 1982; Morrison and Hero 2003). *Hyla gratiosa* is the largest native hylid in the southeastern United States (Mount 1975), and in comparison to other closely-related hylids, has both a higher maximum and a greater range of variation in clutch size. In this study, *H. gratiosa* clutch size was found to range from 459 to 4381 eggs. In comparison, *H. cinerea* average clutch size ranges from 700 to 1472 (Garton and Brandon 1975; McAlpine 1993) and *H. squirella* average clutch size ranges from 957 to 1059 (Brugger 1984; Wright 1932). Limited evidence indicates that *Hyla gratiosa* females may oviposit more than one egg clutch each season (Perrill and Daniel 1983), so it is possible that some of the variation in clutch size for *H. gratiosa* is due to females ovipositing smaller second clutches.

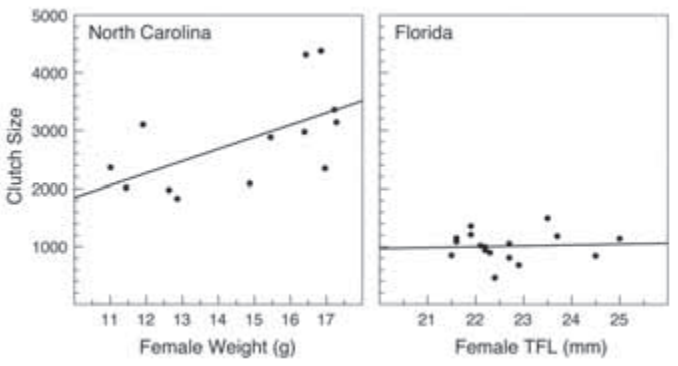

FIG. 1. Female body size and clutch size for *Hyla gratiosa* from the Florida population (N = 17) and North Carolina (N = 13).

Female size was more strongly correlated with clutch size for *H. gratiosa* from NC relative to FL. This could be due to differences in the measurement of adult size between the two data sets (mass and TFL, respectively) or differences between locations in the range of female body size. Future studies of reproductive ecology of this species should include both measurements of body size. Mean egg diameter was similar in this study in NC (Table 1) to that measured from a single clutch in the Okefenokee Swamp (mean = 1.37, SD = 0.19, N = 29, Wright 1932). The relationship between clutch size and egg size warrants further investigation as this study suggests that, at least in the NC population, larger females lay larger clutches of larger eggs. Although limited in scope, this study suggests there may be significant variation in reproductive characteristics of *H. gratiosa*.

Acknowledgments.—We thank C. G. Murphy for assistance collecting *H. gratiosa* amplexed pairs in Florida. This research was conducted under Florida State University ACUC protocol # 0115. We acknowledge the support of the National Science Foundation (grant DEB 99-03925 to JT) and the Amphibian Research and Monitoring Initiative of the USGS during research and manuscript preparation.

The Guiana region of northeastern South America is an area of high biodiversity, and the varied habitats on the tepuis of the region support a significant portion of this diversity. The zoogeography of the pantepui region has been a recent topic of interest, with several sources of published data (Duellman 1999; Gorzula and Señaris 1999; Hollowell and Reynolds 2005a; Hoogmoed 1979a; McDiarmid and Donnelly 2005).

The herpetofaunal communities of several tepuis have been described (Donnelly and Myers 1991; Gorzula 1992; McDiarmid and Paolillo 1988; Myers 1997; Myers and Donnelly 1996, 1997, 2001). Mount Roraima, the most famous of these table mountains, has been explored extensively (McDiarmid and Donnelly 2005). Although numerous specimens have been collected on Roraima, these collections have never been summarized or analyzed.

Roraima (05º12'N, 060º44'W) is one of the highest points in northeastern South America, and it marks the boundary between Guyana, Venezuela, and Brazil. The summit plateau, from 2600 to 2810 m elevation, is some 34 km^2 in area. The plateau is known for its varied rock formations, and for its very sparse vegetation. The summit is at the top of steep walls which extend from below 2000 m up to 2600–2700 m; these walls are occasionally broken by more gradual slopes. At the bottom of the vertical walls, below about 2000 m, the tepui is surrounded by forested slopes. The forest is most extensive below 1500 m, with only a narrow band encircling the mountain above this elevation. Descriptions of the physical features and vegetation of Roraima are in Huber (1995a, b).

Herpetofaunas on tepui summits often differ in species composition from faunas on tepui slopes. Summit faunas are often more depauperate than slope faunas (Myers and Donnelly 2001). Both elevation and microhabitat can affect species distributions, and many species occur over a range of elevations (McDiarmid and Donnelly 2005). It is therefore worthwhile to have a compilation of slope and summit species, for comparison with faunas on other mountains.

The first aim of this paper is to compile a list of the known herpetofauna of Roraima, from both summit and slopes. The second aim is to compare the Roraima herpetofauna with those of other tepuis in the Guiana Shield (following Hollowell and Reynolds 2005b, p.1); this consists of 1) comparison using criteria developed by McDiarmid and Donnelly (2005), and 2) the hypotheses of tepui zoogeography of Myers and Donnelly (2001), who enumerated five general points about the composition of tepui herpetofaunas. Such comparisons can provide valuable insight about the zoogeography of the region.

Methods.—Information was taken from museum records or published literature. Amphibian taxonomy follows Faivovich et al. (2005), Frost et al. (2006) and Grant et al. (2006); reptile taxonomy follows Avila-Pires (2005). Institutional abbreviations follow Leviton et al. (1985), with the following additions: CSBD – Centre for the Study of Biological Diversity, University of Guyana, Georgetown, Guyana; MHNLS – Museo de Historia Natural La Salle, Caracas, Venezuela (formerly SCNLS); ULABG – Laboratorio de Biogeografia, Universidad de Los Andes, Mérida, Venezuela.

The aims of this study require that two points be defined. First, what are the boundaries of Roraima? Second, what are highland species? These questions were resolved as follows:

Roraima: We defined the boundaries of Roraima as that part of the mountain which is above 1500 m. Although some studies of the Guiana Shield region have used 1000 m as a minimum elevation (e.g., Hoogmoed 1979a), the use of this criterion at Roraima would necessitate the inclusion of the extensive surrounding uplands, and would increase the boundaries of Roraima to an unrealistic extent. We therefore adopted the 1500 m criterion, as have other studies of the Guiana fauna (Gorzula and Señaris 1999; McDiarmid and Donnelly 2005).

Because of the potentially great difference between faunas on tepui summits and faunas on forested tepui slopes, we have indicated the location from which each species was recorded, in order to determine whether each is part of the summit or slope faunal assemblages. The habitat on the slopes of Roraima is varied, ranging from steep rocky walls to more gently sloping forested areas (Huber 1995a, b).

Highland Species: Highland species are those which typically occur above 1500 m; any such species is here considered a highland species, although it may have been occasionally collected below 1500 m. McDiarmid and Donnelly (2005) followed a similar procedure. Although a highland species may occasionally occur at elevations below 1500 m, it will not be widespread below that elevation. Table 1 contains all species reported from above 1500 m, plus several highland species collected slightly below

TABLE 1. Amphibians and reptiles collected from Mount Roraima. G = Guyana, V = Venezuela. Species marked with (h) are considered to be highland species, seldom occurring below 1500 m.

1500 m (between 1400 and 1500 m) on Roraima.

Comparisons: Not all species in Table 1 are included in that part of the Discussion concerning comparisons among tepui faunas. In order to make the comparisons as valid and accurate as possible, we used the same criteria as those used by other studies to which we compare the Roraima fauna. Two types of comparisons are made. The first is based on elevational and distributional ranges of species occurring on each mountain as defined by McDiarmid and Donnelly (2005). These authors (2005, p. 483) examined the elevational ranges (ER) and distribution patterns (DP) of tepui species. Elevation ranges and distribution patterns are weighted according to their extent, and the weighted results are added to produce two values: Sum of elevational ranges (SUMER) and Sum of distribution patterns (SUMDP), which reflect the composition of each tepui community. Only those species which occur above 1500 m are used in this comparison. The second type of comparison is based on the hypotheses of tepui herpetofaunas proposed by Myers and Donnelly (2001); only those species which fit the above definition of highland species are used in this comparison.

Results.—The search of institutional records and published literature turned up 14 amphibian and 8 reptile species in 18 genera and 13 families occurring on Roraima. These taxa are shown in Table 1. Where data such as coordinates, elevation and precise location are known, they are provided in the table.

Several changes have been made to information from the literature. These are as follows:

1) Phelps (1938) determined that the specimens collected by McConnell and Quelch, reported in Boulenger (1900a, b) as being from Guyana, were actually collected in Venezuela. Table 1 follows this determination.

2) Rivero (1961) reported two species of *Leptodactylus* from the summit of Roraima in the AMNH collection: *L. sibilatrix* AMNH 39752 and *L. podicipinus petersi* AMNH 39753. However, according to AMNH records, 39752 is *L. fuscus* from Philipp Swamp and 39753 is *L. sabanensis* from a location below 1500 m. Table 1 follows this determination.

3) Gorzula and Señaris (1999, p. 255) reported *Tepuihyla edelcae* from Roraima. However, although *T. edelcae* is reported from Roraima on p. 255, the more detailed species account (p. 49) contains no mention of its presence on Roraima. This species has been collected only from several tepuis to the west of Roraima (Auyán, Chimantá, Los Testigos). Table 1 follows this determination, as do McDiarmid and Donnelly (2005).

4) The latitude given for the north slope of Roraima in Duellman and Hoogmoed (1992) corresponds to a location some 35 km N of Roraima. Following Warren (1973) we have amended this latitude to 05º17'N.

In addition to *Norops chrysolepis*, which has also been recorded above 1500 m (Table 1), 39 additional species, *Chaunus granulosus, C. marinus, Rhinella margaritifer, Anomologlossus* sp., *Stefania scalae, Dendropsophus minutus, Hypsiboas boans, H. crepitans, H. multifasciatus, Scinax ruber, Adelophryne gutturosa, Eleutherodactylus* sp., *Leptodactylus bolivianus, L. pallidirostris, L. petersi, L. sabanensis, Otophryne robusta, Synapturanus* sp., *Lithobates palmipes, Norops auratus, N. fuscoauratus, Polychrus marmoratus, Mabuya nigropunctata, Ameiva ameiva, Arthrosaura guianensis, Cnemidophorus lemniscatus, Kentropyx calcarata, K. striata, Neusticurus rudis, Boa constrictor, Leptodeira annulata, Liophis lineatus, Liophis typhlus, Mastigodryas bifossatus, M. boddaerti, Oxybelis aeneus, Tantilla melanocephala, Micrurus lemniscatus,* and *Bothrops atrox*, were collected on the slopes of Roraima below 1500 m (Barrio 1998; Boulenger 1900a, b; Campbell and Clarke 1998; Heyer 1994; Hoogmoed 1979b; Rivero 1961).

Discussion.—Seventeen species have been collected from above 1500 m on Roraima. Numbers of species collected on Roraima are compared to collections from some other tepuis in Table 2. In order to ensure that such comparisons are as meaningful as possible, only large, frequently-visited tepuis in the eastern Guiana region are included in the table. There are few such tepuis; for this reason we include Guaiquinima, even though it does not reach 1500 m.

Roraima's diversity is lower than that on other comparable tepuis (Table 2), despite having been visited by collectors at least as often as have other tepuis. While other large tepuis have forested slopes which support considerable faunal diversity, Roraima's slopes are mostly steep rocky walls, with only a narrow forested band above 1500 m. The summit of Roraima also supports little vegetation, and its area is smaller than the summits of other tepuis (Huber 1995a). Thus, the limited amount of suitable habitat on Roraima may account for its low faunal diversity.

Faunal composition on the slopes of Roraima changes with elevation, and there is no overlap between the slope and summit faunas. The faunal changes are summarized in Table 3. Specimens have never been collected systematically along an elevational transect on the slopes of Roraima; most are from the vicinity of locations which are suitable for camping. It is possible that elevational changes in faunal composition are partly an artefact of

collecting efforts. For example, the Hylidae, which are very diverse at lower elevations, are not represented above 1500 m. However, several highland species (*Hyla warreni*, *Hypsiboas roraima*, *H. sibleszi*, *Myersiohyla kanaima*, *Stefania roraimae*) were collected between 1400 and 1500 m on Roraima. All of these have been collected above 1500 m on other tepuis, and it is possible that they occur above 1500 m on Roraima as well.

Only four species (*Oreophrynella quelchii*, *Eleutherodactylus marmoratus*, *Eleutherodactylus* sp. [USNM], *Riolama leucosticta*) are known from the summit of Roraima, with *Anomaloglossus roraimae* collected from a location just below the summit. Tepui summit faunas are typically depauperate, but nonetheless this number is somewhat lower than the numbers of species collected on the summits of other frequently-visited tepuis (McDiarmid and Donnelly 2005; Myers and Donnelly 2001).

The remaining species (Table 1) were recorded from a variety of habitats on the slopes of Roraima. Some slope species have been reported only from higher elevations elsewhere, such as *Hyla warreni* (MacCulloch and Lathrop 2005), *Stefania roraimae* (MacCulloch and Lathrop 2002) and *Otophryne steyermarki* (Barrio 1999; Campbell and Clarke 1998; Myers 1997), but many reptile species have been reported from a broad range of elevations.

Some genera which have been collected in several other highland locations in the Guiana Shield (e.g., *Hyalinobatrachium*, *Tepuihyla*, *Thamnodynastes*) have not been collected on Roraima.

McDiarmid and Donnelly (2005, p. 512) listed elevation ranges for many Guiana Shield species. Table 1 increases the elevation ranges for *Oreophrynella quelchii*, *Otophryne steyermarki*, and *Tropidurus hispidus*.

Comparisons: Elevational ranges (ER) and distribution patterns (DP) of tepui species were examined by McDiarmid and Donnelly (2005). Elevational ranges and distribution patterns for the Roraima community are in Table 4; SUMER = 648 and SUMDP = 739. These values are similar to those presented by McDiarmid and Donnelly (2005) for other large tepuis. SUMER and SUMDP for Roraima, and for other tepuis, will undoubtedly change as knowledge of the fauna increases.

Myers and Donnelly (2001, p. 79) established five general statements concerning tepui herpetofaunas. The assembled data from

TABLE 4. Elevational ranges and distribution patterns for the 17 species which occur above 1500 m on Mount Roraima. Distribution patterns (from McDiarmid and Donnelly 2005): HR = highly restricted (occurs on only one tepui); MR = moderately restricted (two or more tepuis); GE = Guiana endemic; WS = widespread.

Species	Elevational Range (ER) (m)	ER Weighting Factor	Distribution Pattern (DP)	DP Weighting Factor
Anomaloglossus praderoi	1800–1950	1	HR	1

Tepuihyla sp.					X	Villarreal et al. 2002
Riolama leucosticta	X	X		X		Gorzula and Señaris 1999

Roraima are examined below to determine the extent to which they support these five points.

Point 1: tepuis have relatively depauperate herpetofaunas. This is true for summit faunas. The Roraima summit fauna consists of four species; the fauna on other tepui summits ranges from zero to 15 species (McDiarmid and Donnelly 2005; Myers and Donnelly 2001, see also Table 5). Herpetofaunas on the slopes of tepuis are usually more diverse.

Point 2: neighboring tepuis are likely to have significantly different faunas. Although Myers and Donnelly (2001) did not quantify the definition of neighboring tepuis, they used Auyán and Chimantá, which are 50 km apart, as examples. Therefore we use this distance as a criterion, and consider tepuis within 50 km of Roraima to be neighboring tepuis.

Four tepuis within a 50-km radius have been visited: Kukenán (05º13'N, 060º51'W, 2650 m elev.), Yuruaní (05º19'N, 060º51'W, 2300 m elev.), Ilú (05º25', 060º59'W, 2700 m elev.), and Wei-Assipu (05º13'N, 060º42'W, 2400 m elev.). Although some specimens have been collected on the slopes of Kukenán (Gorzula and Señaris 1999; Rivero 1961), collections from Ilú, Yuruaní, and Wei-Assipu were made only on the summits, accessed by helicopter (Gorzula and Señaris 1999; Villarreal et al. 2002). Therefore only the summit faunas will be used for comparison among these five tepuis (Table 5). Collections from Kukenán contained one amphibian species (*Oreophrynella nigra*) which has not been collected on Roraima. Specimens from Wei-Assipu include four species which have apparently not been collected on Roraima, although three of these are identified only to genus. The Wei-Assipu community also includes one genus (*Tepuihyla*) which has not been reported from Roraima.

The herpetofauna of Wei-Assipu is more diverse than those of the neighboring tepuis Roraima, Kukenán, Ilú, and Yuruaní. This may be because of summit habitat; on the latter four tepuis the summit is rocky and vegetation is sparse (Señaris et al. 1995, 1997), while the summit of Wei-Assipu supports more vegetation (Villarreal et al. 2002).

Only three species, *Oreophrynella nigra*, *O. quelchii*, and *Riolama leucosticta*, occur on more than one tepui. The ten remaining species are found on only one of the five, although two also occur at more distant locations (*Eleutherodactylus marmoratus* and *Hyla warreni*).

Although *Oreophrynella* are found on all five tepuis, and *Riolama* on three, other genera and even families exhibit little overlap. The summit faunas of these neighboring mountains are quite different. This situation is similar to that observed on Auyán and Chimantá (Myers 1997).

Point 3: tepui endemics outnumber widespread highland species. Expanding on the criterion established in Point 2, we consider any species from Roraima which also occurs in one or more locations more than 50 km distant from Roraima to have a widespread distribution. Using this criterion, seven of the highland species occurring on Roraima have been reported from locations at distances of 50–200 km from Roraima, and are therefore considered widespread species. These are *Stefania roraimae* (MacCulloch and Lathrop 2002), *Hyla warreni* (MacCulloch and Lathrop 2005), *Hypsiboas roraima* (MacCulloch and Lathrop 2005), *H. sibleszi* (Duellman 1997; Hoogmoed 1979b; MacCulloch and Lathrop 2005), *Myersiohyla kanaima* (Duellman and Hoogmoed 1992; Goin and Woodley 1969; MacCulloch and Lathrop 2005), *Eleutherodactylus marmoratus* (Frost 2004), and *Otophryne steyermarki* (Barrio 1999; Gorzula and Señaris 1999).

Of the four Roraima summit species, only *Eleutherodactylus* sp. (USNM) is endemic. Of the highland slope species only four (*Oreophrynella macconnelli*, *Anomaloglossus praderoi*, *Anomaloglossus roraimae*, *Pseudopaludicola* sp. [MHNLS]) have never been reported from elsewhere and can be considered endemic. On Roraima, widespread highland species outnumber endemics.

Point 4: some endemic species have counterparts on other tepuis. This point is supported by the Roraima data. The genera *Oreophrynella*, *Eleutherodactylus* and *Anomaloglossus* are good examples of this phenomenon.

Point 5: lowland species find their way onto tepuis in an irregular, unpredictable manner. This point is well supported by the Roraima data. Several lowland species, *Leptodactylus fuscus*, *Mabuya nigropunctata*, *Tropidurus hispidus*, *Liophis breviceps*, *Bothriopsis taeniata* and *Crotalus durissus*, occur above 1500 m on Roraima. Some of these species (*Leptodactylus fuscus*, *Tropidurus hispidus*, *Bothriopsis taeniata*, *Crotalus durissus*) have also been reported from high elevations elsewhere (Donnelly and Myers 1991; Gorzula and Señaris 1999; McDiarmid and Donnelly 2005; Means 2004).

The Roraima data support Points 2, 4, and 5 well, but provide little support for Points 1 and 3. Some points appear to apply more to summit faunas than to slope faunas.

The Roraima herpetofauna is a mixture of high- and low-elevation taxa, similar to the faunas on numerous other tepuis in the Guiana Shield region. Although knowledge of the region's amphibians and reptiles is far from complete, the situation will improve as more of the region is explored, and as previously collected locations are revisited.

Acknowledgments.—We thank the following, who generously provided or offered data from their collections: L. Ford and D. Kizirian (AMNH), J. W. Arntzen (RMNH), J. A. Campbell (UTA), E. Gilmore (ANSP), E. La Marca and L. Esqueda (ULABG), J. Simmons and D. McLeod (KU). R. W. McDiarmid, G. Köhler, and two anonymous reviewers made valuable comments on an earlier version of the manuscript. This is contribution 332 of the Centre for Biodiversity and Conservation Biology, ROM and number 111 in the Smithsonian's Biological Diversity of the Guiana Shield Program publication series.

Invertebrates are known predators of both aquatic and terrestrial stages of amphibians (reviewed in McCormick and Polis 1982; Toledo 2005). Seventy-three percent of reported predation events in and out of the water on anurans involved spiders (ca. 48%) and water bugs. The remainder included crabs, leeches, and various insect groups (Toledo 2005). A review of the published information on predation of juvenile and adult amphibians by beetles revealed reports on predation by adult carabids (Huheey and Stupka 1967; Littlejohn and Wainer 1978; Ovaska and Smith 1988; Robertson 1989; Smith 1946), dytiscids (Hinshaw and Sullivan 1990), cicindelids (McCormick and Polis 1982) and staphylinids (Jung et al. 2000).

There are three reported cases of terrestrial beetle larvae preying on amphibians, all belonging to the carabid tribe Chlaeniini (= Callistini). Shiina and Tachikawa (1988) reported how *Epomis nigricans* larvae ambush *Hyla* sp. and *Rhacophorus schlegelii* on vegetation and prey upon them (shown in photographs by Tachikawa 1994). There is a preliminary report from South Africa on carabid beetle larvae associated with *Bufo* sp. (Moore 1971). That author received two preserved first instar larvae identified as Chlaeniini, which had been found attached by means of the mandibles to the hind leg of a toad. No further information was given as to whether the described larvae were able to kill or physically harm the toad.

While studying the population dynamics of the Green Toad (*Bufo viridis*), a species that was recently declared endangered in Israel (Gafny 2004), we encountered on several occasions a carabid larva attached to Green Toad and Yellow Lemon Tree Frog (*Hyla savignyi*) metamorphs. We describe here the predation behavior and its frequency of occurrence in the central coastal plain of Israel, together with a description of the beetle's larval development and pupation.

Methods.—We monitored *Bufo viridis* breeding populations in the central coastal plain of Israel (0–50 m elevation) at seven rain pools over a period of four years (2002–2005), at two pools for two years (2002–2003), and at one pool for one year (2006). We searched seasonally for metamorphs under cover items including logs, stones and debris, along the edge and in the vicinity of the rain pools. Each site was sampled regularly every two weeks, starting in the third week of March, until no additional metamorphs were located at the site for at least two consecutive visits. All metamorphs were transferred to the laboratory for inspection of malformations or other signs of abnormality and were then returned to the collection site. Among them we found beetle larvae

attached to metamorphs. In spring 2005 and 2006, we conducted laboratory observations to study larva-metamorph interaction.

In spring 2005, we conducted laboratory observations of three pairs of beetle larvae and toad metamorphs. Two beetle larvae (one first-instar and one second-instar) were detached from *B. viridis* metamorphs and one single larva (second-instar) was found in the collection container. Beetle larvae were placed individually in 500 ml circular semitransparent plastic containers, and kept indoors at 20–24°C, under a natural photoperiod (L/D, 14:10). Each container held about a 3-cm-deep mixture of peat and coconut fiber bedding that was kept moist. A piece of crumpled tissue paper was added to provide the larvae with substrate for successful molting and for cover. A single toad metamorph was placed into each of the three containers. When a metamorph was consumed, the larva was presented with an additional *B. viridis* metamorph. If the beetle larva did not respond within several hours, the metamorph was removed and offered again on the next day. The metamorphs in the experimental containers were left unfed. In a second set of feeding trials, to examine the diet specificity of the carabid larvae, we offered larvae a selection of macroinvertebrates that they might encounter in their natural habitat. These included house crickets (*Acheta domestica*), snails (*Xeropicta vestalis*) and earthworms (*Lumbricus* sp.). We also tested larval response to mealworms (*Tenebrio molitor*). Larval development was monitored continuously through all molting stages, pupation and adult emergence, to identify the beetle species.

In the following winter (February 2006) we collected four adult beetles (2 females, 2 males) at a rain pool site (Dora; 32°18'N, 34°11'E). We placed the beetles in a 5 L rectangular semitransparent plastic container, indoors at 24–26°C, under a natural photoperiod (L/D, 14:10). The container had bedding similar to that described for the observations in 2005. At least 45 eggs were laid, three were preserved and the rest were left to hatch (all hatched). We repeated the predation experiment following the procedure performed in 2005 with 12 beetle larvae and *B. viridis* metamorphs (reared in the laboratory from tadpoles collected from a drying pool). In addition, three first-instar beetle larvae hatched in captivity were retained in containers but not fed. The remaining hatched larvae were retained and fed metamorphs to document their development.

Results.—Predatory interactions of carabid beetle larvae on anuran metamorphs were found for both *B. viridis* and *H. savignyi* collected in the vicinity of rain pools. We examined a total of 4907 metamorphs, and 909 juveniles and adults of *B. viridis*, as well as occasionally encountered adults (N = 64) and metamorphs (N = 1894) of *Hyla savignyi*. Predation interactions were recorded for less than 0.5% of each of the above anuran species, between April 25 to May 22, at 3 of 10 sites studied. At one site (Hadera-West; 32°96'N, 34°17'E), we encountered 8 carabid larvae attached to metamorphs of *B. viridis* and one to a metamorph of *H. savignyi*. At another site (Dora), we recorded one carabid beetle larva attached to a metamorph of each of the above anurans. Upon checking cover objects in a dried pool (Qadima, 32°27'N, 34°89'E), we observed a first instar carabid larva moving around among a group of *B. viridis* and *H. savignyi* metamorphs. When introduced into a container that held a *B. viridis* metamorph, the beetle larva immediately attached to the metamorph's forelimb. Under a different cover object at the same site we observed a second instar larva attached to a *B. viridis* metamorph.

The attacked *B. viridis* metamorphs were 12–33 mm SVL, and weighed 0.24–3.8 g; *H. savignyi* were 15.5–23.5 mm SVL and weighed 0.3–1.06 g. A single beetle larva was found per anuran individual. In the case of *B. viridis*, 7 were attached to the abdominal area, one to the hind limb, one to the lower jaw and one to the back of the head. For *H. savignyi*, one larva was found attached to the back, and the other to the forelimb. The larvae were strongly attached to the metamorphs' skin by the mandibles and force was needed to dislodge them from the prey, which was left with deep skin lesions (photographs available at: http://www.tau.ac.il/lifesci/departments/zoology/Amphibia/index.html).

Analysis of predation behavior of the beetle larvae on metamorphs is based on laboratory observations of 3 larvae in 2005 and 12 in 2006. Free beetle larvae were relatively inactive during the day, but moved around on the soil surface at night. Upon presentation of a toad metamorph, each larva responded vigorously, grasping the prey's skin with its mandibles. Some toads tried unsuccessfully to rid their body of the larva, but eventually continued apparently normal behavior. Feeding of the beetle larvae on small metamorphs (< 16 mm) appeared to first entail sucking of their body fluids, which lasted less than an hour, and was then followed by chewing of soft tissue. Sucking of larger metamorphs lasted up to 32 h, during which the larvae also changed their attachment position on the prey's body. The larva's body progressively inflated and increased in size while that of the prey shrunk. The larva, which sucked the prey's fluids completely, concomitantly released liquid droplets from its anus. Only 2 of 45 metamorphs survived being preyed upon by the beetle larvae in the laboratory studies (2005–2006), and both were > 29 mm SVL. The larva either moved away from the dead metamorph, or started chewing it, leaving behind only skin and bones (photographs available at: http://www.tau.ac.il/lifesci/departments/zoology/Amphibia/index.html). In 2006, three first-instar larvae were kept without metamorphs and survived for six days.

To examine diet specificity we also presented the carabid larvae with invertebrates that they might encounter in their habitat. In only one of six trials did a larva respond to an earthworm and grab it; and this occurred only after repeated presentations directly in front of its mandibles. It sucked the worm and killed it, as observed for the toads. House crickets, snails and mealworms were ignored.

Beetles emerged in captivity in 2005 were identified as *Epomis dejeani*, Chlaeniini (Dejean 1831, cited in Makarova 2005), a species widely distributed throughout the eastern Mediterranean, the Crimea, southern Russia and central Asia (Winkler 1932). In 2006, we observed adult *E. dejeani* in moist soil in the vicinity of rain pools (Hadera West, Dora) under the same type of cover used by anuran metamorphs. The 4 adult beetles collected in February 2006 laid eggs 32 days later. Six days after spotting of the eggs the first larvae hatched. Hatching continued for another 10 days. The duration of the instar stage progressively decreased from a maximum of 7 days of the first instar to 4 of the third instar (Table 1). In 2005, larval period above-ground lasted 18–24 days (N = 3), while in 2006 it was 8–9 days shorter (Table 1). Construction of the pupation chamber was completed within a period of five days (N = 2, 2005). The pupation period lasted 8 days. The adults remained in the pupating chamber for another 3 days and then

TABLE 1. Developmental stage, duration, and size of *Epomis dejeani* larvae observed under laboratory conditions in 2006, and number of toad metamorphs consumed per larval instar stage. Number in parentheses indicates sample size. NA: not applicable.

Developmental stage	Duration (days)	Length (mm)	Consumed prey
1st instar	4–7 (12)	5–11 (7)	1 (9)
2nd instar	3–5 (10)	7–18 (10)	1 (9)
3rd instar	2–4 (7)	11–27 (8)	4 (5)
Underground period	19; 21 (2)	NA	NA
Total	31; 37 (2)	NA	6

emerged (males, 16 and 18 mm). In 2006, the underground period until emergence lasted 19 and 21 days (N = 2, females, each 19 mm).

First and second instars each consumed one *B. viridis* metamorph. Third-instar larvae presented with metamorphs larger than 16 mm SVL consumed two toadlets per larva (2005 experiment), whereas those presented with smaller prey consumed four (2006 experiment, Table 1). In one case we observed a first-instar larva attached to a second-year juvenile *B. viridis* (50 mm SVL). It completed first, second and third instar stages on the same individual, ultimately killing it.

Discussion.—This is the first detailed description of predation on juvenile anurans (*Bufo viridis* and *Hyla savignyi*) by a terrestrial beetle larva (*Epomis dejeani*). *Epomis dejeani* belongs to the carabid tribe Chlaeniini in which most species are well-known hemi-cryptobionts (i.e., organisms colonizing hidden surfaces; Makarova 2005) of humid, clay-type soils (Thiele 1977). The genus *Epomis* comprises of about 20 species, found mainly in tropical Africa and south and southeastern Asia; five species are known from the Palaearctic region, among them *E. dejeani* (Kryzhanovskij 1983). The larva of this species was first described in 2005 (Makarova 2005). Representatives of the tribe in Israel are often found around the edges of water bodies (Schweiger 1989; A. Gasith, unpubl. data). In our study, *E. dejeani* was found in clay-type and sandy soils around rain pools. These habitats are major breeding sites of *B. viridis* and *H. savignyi* in Israel. Along the coastal plain, metamorphs of both anuran species emerge from the pools in late March and early April. They seek cover in moist soil in the vicinity of the pools until leaving the breeding sites in late May through June (E. Elron, unpubl. data). Larvae of *E. dejeani* are also active during this period. Most carabid larvae and adults are polyphagous, feeding on a wide range of soil invertebrates (Ekschmitt et al. 1997; Lövei and Sunderland 1996). Larval feeding behavior resembles parasitism in the initial phase (sucking body fluids) and can develop into typical predation (tissue ingestion) at the end. They encounter and attack anuran metamorphs on the ground near breeding sites during a relatively short window of opportunity, from late April to late May. Encounters between the beetle larvae and anurans are inevitable because both use the same moist habitats at the same time. Whereas *E. dejeani* larvae attack the prey on the ground, larvae of *E. nigricans* were reported to ambush amphibians on vegetation (Shiina and Tachikawa 1988). Our findings on *E. dejeani* together with the reports on predation of anurans by *E. nigricans* in Japan (Shiina and Tachikawa 1988; Tachikawa 1994) and South Africa (Moore 1971), indicate that this phenomenon is not a peculiar predation behavior of a single Chlaeniini species. Such predators can be categorized as "temporary specialized predators," a term used by Toledo et al. (2007) for vertebrate predators "who look specifically for anurans in a determined phase of their life cycle or for a determined purpose."

Epomis dejeani appear to complete larval development in 40 days or less, consuming four or more anuran metamorphs. This is similar to the life history reported for *E. nigricans*, which completes its life cycle in a month, consuming three anurans (Shiina and Tachikawa 1988). In only one-third of the cases studied (N = 333) were arthropod predators smaller than their vertebrate prey (Toledo et al. 2007). This is also the case of *E. dejeani* larvae, which consumes prey many times larger than their size (5–20 fold in weight). This allows the predator to efficiently supply its energetic needs while impacting a relatively small number of prey. In the present study all affected metamorphs were found with a single larva attached to their body. We have evidence for one case in which a *B. viridis* metamorph was attacked by two carabid larvae simultaneously (M. Vonshak, pers. comm.; Sde Boqer, 30°52'N, 34°46'E, Israel, July 1997).

The carabid larva is a newly reported predator of amphibians. The apparently low frequency of occurrence (< 0.5%) of this interaction and the relatively small number of prey affected per beetle suggest a limited effect on amphibian populations.

Acknowledgments.—We are grateful to P. Brandmayr, T. Zetto-Brandmayr, V. Taglianti, T. Bonacci, and V. Chikatunov for their assistance in identification of the carabid beetle. We thank L. Friedman and G. Wizen for technical assistance and M. Guershon, R.J. Brown, D.H. Olson, and an anonymous reviewer for their constructive comments on the manuscript. We also thank N. Paz for editorial assistance. The research was supported by the Porter School of Environmental Studies, Tel Aviv University (grant number 02-004). Animals were collected under permits of the Nature and Parks Authority, Israel (number 17630).

Copperheads (*Agkistrodon contortrix*) and Cottonmouths (*A. piscivorus*) are closely related species that are sympatric throughout much of their range (Conant and Collins 1998). Although these species overlap in geographic range, reported habitat use by these species differ (Gloyd and Conant 1990; Roth 2005). The differences in habitat use most likely reflect differences in prey preference between the two species (Fitch 1999). Copperheads are primarily upland species and feed on small mammals, cicadas, and upland frogs while cottonmouths are lowland species and feed primarily on fish, thus its given specific eptithet *piscivorus* meaning piscivor or fish eater (Conant and Collins 1998). Although both *Agkistrodon* species are opportunistic feeders (e.g., Lutterschmidt et al. 1996; Roth et al. 2003) and may demonstrate considerable overlap in diet, each species demonstrates unique food habits characteristic to the prey availability within their preferred microhabitat.

Because differences in diet may introduce different bacterial microflora to the oral cavity and esophageal track, we conducted an investigation to inventory the common bacterial microflora of the anterior digestive tract and to address the following questions: 1) Does the bacterial microflora in the oral cavity and esophageal tract differ between *A. contortrix* and *A. piscivorus*?; 2) Do differences in bacterial microflora support the differences in diet and food partitioning between the two *Agkistrodon* species?; and 3) Do wild caught snakes have a greater richness of bacterial microflora in the esophageal tract than captive snakes fed only a diet of laboratory mice (*Mus musculus*)?

Both freshly captured and captive snakes were obtained from populations located in Walker Co., Texas, USA. The four freshly captured snakes (two *A. contortrix* and two *A. piscivorus*) were collected from sampling sites that included FM 2821, the Center for Biological Field Studies (CBFS) and Harmon Creek. These snakes were brought back to the laboratory and immediately sampled for bacteria in their anterior digestive tracts. The four captive snakes used in this study were from the captive snake colony housed in the Lutterschmidt Physiological Ecology Research Laboratory at Sam Houston State University. Theses snakes were housed and fed only laboratory mice (*M. musculus*) for at least one year.

Bacterial microflora were sampled only once from each snake by allowing each snake to crawl into a plastic tube for safe handing and straight positioning of the snake's body for oral and esophageal swabbing. A sterile cotton swab (ca. 30 cm in length) was inserted into the mouth and slowly pushed into the esophageal tract. The swab was inserted to approximately a fourth of the snake's body length and slowly retracted. Once removed, the cotton end of the pharyngeal swab (i.e., sample of both the oral cavity and esophageal tract) was broken off into 15 ml Falcon polystyrene conical tubes (Becton Dickinson and Co., Franklin Lakes, New Jersey) containing 5 ml of Butterfield's buffer. Serial dilutions were prepared for each sample and cultured aerobically at 35°C for 24 h on MacConkey agar for the isolation of Enterobacteriaceae. Isolated colonies were subcultured onto tryptic soy agar and cultured aerobically at 35°C for 24 h. Colonies that were oxidase negative were emulsified into 5 ml of sterile 0.85% NaCl (Leboffe and Pierce 2002). API 20E strips (bioMerieux, Inc., Hazelwood, Missouri) of 20 microcupules containing dehydrated substrates were inoculated according to directions supplied by the manufacturer. All reactions were read after 24 h. Each isolate was identified by using the API 20E profile index.

Only enteric species richness was tabulated for comparison of bacterial microflora among wild and captive *A. contortrix* and *A. piscivorus*. Blaylock (2001) found that most oral bacteria (81.5%)

were Enterobacteriaceae. Jaccard binary similarity coefficients for presence/absence data were used to investigate community similarity of bacterial microflora (Krebs 1999).

We identified 21 (15 to species level and 6 to genus level) bacterial species from the esophageal tracts of the eight *Agkistrodon* snakes. The comparison of bacterial microflora from the esophageal tract of wild-caught *A. contortrix* and *A. piscivorus* indicated that only two bacterial species (*Acinetobacter baumannii* and *Citrobacter freundii*) were shared between the snake species. Five bacterial species found in *A. contortrix* were not observed in *A. piscivorus* and seven bacterial species found in *A. piscivorus* were not observed in *A. contortrix* (Table 1). Of the 14 bacterial species found in the esophageal tract of wild-caught snakes, there was little similarity ($S_J = 0.143$) between wild *A. contortrix* and *A. piscivorus*. If differences in esophageal bacteria are influenced by difference in prey ingestion between *A. contortrix* and *A. piscivorus*, this finding may provide additional evidence for food partitioning between these sympatric snake species.

Although captive and wild snakes had similar species richness in bacterial microflora (13 and 14, respectively), there were considerable differences between the bacterial communities. Wild-caught snakes had eight bacterial species that were not observed in captive snakes (Table 1). These bacterial species may be common in the environment allowing these wild *Agkistrodon* snakes to inoculate their esophageal tracks. The presence of only four bacterial species in captive *A. piscivorus* supported our hypoth-

TABLE 2. Jaccard binary community similarity indices for comparisons of bacterial microflora among snake species for both captive and wild individuals.

		Wild		**Captive**	
		A. contortrix	*A. piscivorus*	*A. contortrix*	*A. piscivorus*
Wild	*A. contortrix*	_	0.143	0.200	0.100
	A. piscivorus	0.143	_	0.167	0.182
Captive	*A. contortrix*	0.200	0.167	_	0.231
	A. piscivorus	0.100	0.182	0.231	_

esis that individuals feeding only on one prey type such as laboratory mice (*Mus musculus*) would demonstrate a lower diversity of esophageal bacterial species. These results also agree with findings of Theakston et al. (1990) where captive snakes had fewer positive bacterial cultures. Although captive *A. contortrix* had the greatest number of bacterial species, captive *A. contortrix* and *A. piscivorus* demonstrated the greatest similarity (S_J = 0.231) in bacterial microflora (Table 2).

No study has investigated the bacterial microflora of the esophageal track in *Agkistrodon*. Some clinical work has been done on the antibacterial activity of venom against the bacteria of the oral cavity in crotalid snakes (e.g., Talan 1991). Unlike such clinical investigations, we provide the first inventory and assessment of species richness for common bacteria found in the oral cavity and esophageal tract of any species of *Agkistrodon*. Placing this information in the context of differences in prey use between *A. contortrix* and *A. piscivorus* might prove interesting. If differences in bacterial microflora are correlated with differences in prey ingestion by *A. contortrix* and *A. piscivorus*, then our findings might provide indirect but additional evidence for food partitioning between these sympatric snake species.

Acknowledgments.—We acknowledge a National Science Foundation grant (DBI 0353538) awarded to Diane L. Neudorf and William I. Lutterschmidt that founded this project through the Research Experience for Undergraduates Program within the Department of Biological Sciences at Sam Houston State University. We sincerely thank microbiologists, Drs. Harold F. Foerster and Todd P. Primm, for their comments and suggestions regarding earlier reviews of this manuscript.

Distribution of the Amphibians of Honduras by Departments

JAMES R. MCCRANIE
10770 SW 164 Street, Miami, Florida 33157–2933, USA
e-mail: jmccrani@bellsouth.net

McCranie and Castañeda (2007) recently published a review of the amphibian fauna of Honduras. That review included 124 species verified to occur in the country, an increase of seven species over that published in McCranie and Wilson (2002). Despite these two reviews, a summary of distribution by departments has never been published for the amphibian fauna of Honduras. The purpose of this paper is to present such a summary, an analysis of which should point out which areas of Honduras are understudied.

Materials and Methods.—The generic taxonomy used herein follows the recent changes proposed by Faivovich et al. (2005), Frost et al. (2006a, 2006b), and Nascimento et al. (2005). Also, the taxonomy for the *Ollotis coccifer* complex suggested by Mendelson et al. (2005) is not followed for the reasons discussed by McCranie and Castañeda (2007).

Of the 499 departmental records listed in Table 1, only seven are based on literature records of specimens not examined by me in the work leading up to McCranie and Wilson (2002) and McCranie and Castañeda (2007). These seven records are: *Bolitoglossa conanti* (Santa Bárbara), *Oedipina elongata* (Cortés), *Hyalinobatrachium cardiacalyptum* (Colón), *Plectrohyla dasypus* (Santa Bárbara), *Craugastor rostralis* (Santa Bárbara), *C. stadelmani* (Atlántida), and *Rhinophrynus dorsalis* (Francisco Morazán). A list of these literature records and of all specimens examined was provided by McCranie (2006).

Results.—Examination of Table 1 indicates that two departments (Lempira and Santa Bárbara) are clearly understudied. Lempira has only 13 species verified from within its limits, whereas Ocotepeque and Intibucá, which border Lempira on either side, have 20 and 25 species, respectively. However, a better indication of Lempira's poorly-studied status is demonstrated by the absence of records for *Scinax staufferi* and *Smilisca baudinii*, both of which are otherwise known from each of the 17 remaining Honduran departments. Also, no records of *Lithobates brownorum*, or *L. forreri*, or their putative "hybrids" have been recorded from Lempira, again the only department not represented by vouchers. Santa Bárbara has only 25 species verified from within its boundaries, but its neighbor to the west, Copán, has 37 species and Cortés, its neighbor to the north, has 49 species. Thus, Santa Bárbara should be expected to have a number somewhat intermediate between those for those two neighbors. Obvious missing species for Santa Bárbara are *Bolitoglossa rufescens*, *Agalychnis callidryas*, *Craugastor charadra*, *Hyalinobatrachium fleischmanni* (although males thought to be this species were heard calling on the night of 9 October 2006 at Cerro Negro, Santa Bárbara), *Leptodactylus melanonotus*, *Tlalocohyla loquax*, and *T. picta*. Also, McCranie and Castañeda (2007) predicted two species (*Nototriton brodiei* and *Craugastor nefrens*), both of which are known from the moun-

TABLE 1. Distribution by departments of the 125 species of amphibians known from Honduras. Department abbreviations are: ATL = Atlántida; CHO = Choluteca; COL = Colón; COM = Comayagua; COP = Copán; COR = Cortés; EP = El Paraíso; FM = Francisco Morazán; GAD = Gracias a Dios; INT = Intibucá; IBD = Islas de la Bahía; LAP = La Paz; LEM = Lempira; OCO = Ocotepeque; OLA = Olancho; SB = Santa Bárbara; VAL = Valle; and YOR = Yoro. Symbols in the species lists are: X = presence recorded; I = introduced; and H = "hybrid" populations between *Lithobates brownorum* and *L. forreri*.

tains of Guatemala near the border with Santa Bárbara, should also occur in Santa Bárbara.

Colón, with its 31 species, also appears to be understudied. Atlántida, its neighbor to the west has 40 species and Gracias a Dios, its neighbor to the east, has 43 species. Several species otherwise only recorded from the Mosquitia in northeastern Honduras, should also occur in eastern Colón (e.g., *Cochranella granulosa*, *Craugastor mimus*).

The Pacific lowlands of Choluteca and Valle also appear to be understudied. Although badly denuded, there are several species that are recorded from these continuous lowlands both to the west and south, but have not yet been recorded from one or both of these departments (e.g., *Rhinophrynus dorsalis*, *Trachycephalus venulosus*).

Comparison of Clutch Size from Natural Nests and Oxytocin Induced Clutches in the Red-Eared Slider, *Trachemys scripta elegans*

JOHN K. TUCKER
Great Rivers Field Station, Illinois Natural History Survey
8450 Montclaire Avenue, Brighton, Illinois 62012-2032, USA
e-mail: jktucker@inhs.uiuc.edu

The discovery (reviewed by Ewert and Legler 1978) that oxytocin could be used to induce oviposition in captive turtles represented a major innovation for studies of reproduction in turtles. The general presumption in studies using oxytocin to induce oviposition is that the number of eggs released in the laboratory by a particular turtle is the same as the number of eggs that turtle would have deposited in a natural nest. Because of the importance that oxytocin use has assumed in modern studies of turtle reproduction (e.g., Iverson and Smith 1993; Rowe 1994, Tucker et al. 1998a, b), it is appropriate to compare clutch sizes from natural nests to clutches from female Red-Eared Sliders (*Trachemys scripta elegans*) induced to oviposit with oxytocin.

The turtles were collected at nesting areas near Stump Lake (N = 131) in Jersey County, Illinois (USA), and from Swan Lake (N = 94) and Pohlman Slough (N = 21) in Calhoun County, Illinois. These localities are on or border the lower Illinois River. Additional turtles (N = 29) were collected from Gilead Slough, a backwater of the Mississippi River in Calhoun County, Illinois. Collecting methods and study sites are detailed in Tucker et al. (1998a, b).

A total of 25 turtles were found in the process of completing natural nests. In each case, the turtle was caught and palpated to determine if any oviductal eggs were retained following nesting. Nests were excavated, and the eggs were removed and counted.

Oxytocin (0.2 ml/kg) was used to induce oviposition in all turtles not found with completed nests. Because some females retain some or all of the complement of oviductal eggs after oxytocin is administered (Congdon and Gibbons 1985), each turtle was palpated to ensure that all eggs had been laid (Iverson and Smith 1993). Palpation is an effective method to detect eggs in this species (e.g., Thornhill 1982). However, when more than one egg per oviduct remains it becomes impossible to accurately count the eggs remaining in the turtle. Thus twelve of the induced turtles that retained more than two oviductal eggs upon palpation were excluded (Tucker et al. 1998a). No turtles making natural nests retained eggs and none were excluded.

The SAS system was used for statistical tests (SAS Institute 1998). Since most egg and clutch parameters are related to measures of female size, analysis of covariance (ANCOVA; female plastron length as the covariate) was used to compare clutch sizes. The resulting least squares means (LSM) are presented in the text along with unadjusted means.

Mean clutch size for 24 natural nests was 14.6 eggs (SD = 2.81, range 9–19 eggs) whereas mean clutch size for 251 turtles induced to oviposit in the laboratory was 14.3 eggs (SD = 3.72, range = 6–30). Once adjusted for plastron length, LSM (14.9 eggs) for natural nests did not differ (p = 0.3067) from LSM (14.2 eggs) for induced clutches. Because nesting behavior or response to oxytocin might vary between locations, we also compared clutches from natural nests and clutches induced by oxytocin from Swan and Stump Lakes where the bulk (21 of 25) of the natural nests were encountered. LSM (14.9 eggs, N = 14 clutches) for Swan Lake and LSM for Stump Lake (15.6 eggs, N = 7 clutches) for clutches from natural nests did not differ from induced clutches at Swan Lake (LSM = 14.1 eggs, N = 80 clutches, p = 0.2248) nor at Stump Lake (LSM = 14.9 eggs, N = 124 clutches, p = 0.6224).

The results confirm that clutch size from clutches induced with oxytocin are statistically equivalent to clutch size for clutches laid in natural nests by *Trachemys scripta elegans*. These results may be widely applicable to other North American temperate turtles but should be confirmed. The present study supports use of clutch size values determined with oxytocin induction along with counts from natural nests, because the values are comparable.

The accuracy of palpation as a method to count eggs in turtles is questionable. However, use of palpation to determine that only one or two eggs are remaining apparently is possible. Had it yielded systematic undercounts of eggs then the means for eggs induced by oxytocin and those for eggs laid in natural nests should have reflected this. Instead means differed by only 0.3 eggs per clutch. Use of palpation may not be applicable to other species. Some species (e.g., Common Snapping Turtle, *Chelydra serpentina*; Spiny Softshell, *Apalone spinifera*) may be too big for palpation to be useful. Others that lay small clutches (e.g., Painted Turtle, *Chrysemys picta*; Stinkpots, *Sternotherus odoratus*) may be more vulnerable to error than those that lay larger clutches. Use of x-rays to determine clutch size may be more accurate in these cases but that hypothesis remains untested.

Acknowledgments.—James B. Hatcher, Moynell M. Tucker, and Jason Uttley assisted with collecting. This work was partially supported by the Illinois Natural History Survey. Collecting was done under Illinois Department of Natural Resources scientific permit authorization to the author.

Life history theory assumes that organisms endeavor to maximize fitness by making the greatest genetic contribution to their population (Begon et al. 2006; Stearns 1992). Fecundity, in turn, is often considered one of the most useful short-term measurements of lifetime fitness (Begon et al. 2006). By understanding how individual life history characteristics interact to regulate fecundity, and therefore fitness, we can draw conclusions about how those influences have shaped adaptation (Lauck 2005; Stearns 1992).

Amphibians are known for their complex and flexible life histories. Many species of amphibians lay eggs in a single mass (e.g. *Ambystoma jeffersonianum* and *A. maculatum*, Brodman 1995; *Eurycea cirrigera*, Guy et al. 2004; *Rana temporaria*, Loman 2001; *Rana sylvatica*, Starnes et al. 2000), allowing easy estimation of clutch size by inspection of natural nest-cover objects and introduced nest-cover objects (e.g., slate tiles, Guy et al. 2004). Other species, however, spread their eggs throughout the environment (e.g., *Tylototriton verrucosus*, Roy and Mushahidunnabi 2001; *Pseudacris triseriata feriarum* and *Hyla chrysoscelis*, Starnes et al. 2000), making estimation of clutch size more problematic. Furthermore, in order to determine how fecundity in amphibians is related to environmental conditions and other female life history traits such as body size, body condition, age, or size and age at metamorphosis, parentage of a clutch must be determined. In past studies, this has primarily been done by sacrificing individuals and determining clutch size via dissection (Chazal and Niewiarowski 1998; Lauck 2005; Redmer 2000, 2002). Other studies have followed individuals until they oviposit, although this typically results in a smaller sample size due to the time restrictions incurred (Giaretta and Menin 2004; Prado and Haddad 2005; Roy and Mushahidunnabi 2001).

An answer to the problem of determining parentage, as well as clutch size for amphibians that do not lay their eggs in a mass, is to capture gravid females during the breeding season and then confine them within their natural environment until they have oviposited. At this point adults can be measured, clutch characteristics determined, and both adults and eggs released without negative effects. In situ cages have been used in the past to rear tadpoles, for hatching eggs, or for containing adult amphibians, however these methodologies utilized bulky, non-collapsible frames or containers (e.g., De Solla et al. 2002; Harris et al. 2001; Hels 2002; Vorndran et al. 2002). Each of these methodologies, however, may prove too cumbersome or difficult to transport in other experimental situations. In response to our need to quantify clutch size of the Arizona Tiger Salamander *Ambystoma tigrinum nebulosum*, a subspecies that lays eggs singly (Collins 1980), we designed a lightweight and collapsible, submersible cage that allows a female to lay eggs within her native pond while permitting efficient collection of eggs. We evaluated our cage in six temporary and permanent ponds at the Mexican Cut Nature Preserve near Gothic, Colorado, USA.

Our "clutch bag" consisted of a cylindrical mesh bag and an internal PVC pipe frame (Fig. 1), which was modified from a design used by Pfennig et al. (1999). The mesh bag was 30.5 cm tall by 100 cm wide, and was made from flexible, galvanized fiberglass screening (New York Wire, Mt. Wolf, Pennsylvania). Each bag was sewn together at a local upholstery using an industrial sewing machine and had a 30.5 cm opening at the top. The supporting frame consisted of a central pipe (90 cm long) and four legs (30 cm long), all constructed from 1/2 in PVC pipe. Two legs were attached to each end of the central pipe using a three way elbow joint. The frames and bags were light to transport and easily assembled and disassembled due to the three way joints, which fit snugly with the PVC pipe without adhesive. These features are especially important when experimental set ups must be transported to remote locations.

Between June 28 and July 11, 2005, metamorphic and paedomorphic female tiger salamanders were collected using dip nets as a part of a long-term life history study of this population (Whiteman and Wissinger 2005). Swollen females were placed in individual cages along with sticks, small rocks and cut sedges from the immediate natural environment for oviposition. The opening to each bag was fastened shut using a plastic "chip clip", typically found in most grocery stores. Bags were placed so that only 2–3 cm of the cages were above water level. The cages were generally placed in the shade, however when shade was not available spruce boughs were placed on top of the cages to prevent overheating. Cages were checked for eggs every one to two days, and no female was left in their cage for more than five days. Any eggs found were counted and immediately released into the pond, except for ~15 eggs per female, which were kept for genetic analysis (Gerlanc unpublished data). In instances when females had not immediately laid eggs, the female was assumed to have not yet mated, and a sexually mature male was added to the bag for 24 h. If females still did not produce a clutch, it was assumed that females had laid prior to being captured and placed in a clutch bag.

Twenty-two of the 29 females placed in bags laid eggs, and none of the females appeared adversely affected by their containment. No salamanders escaped, and the easily manipulated bags allowed efficient counting of eggs. The frames also provided a safer enclosure than previous designs, which were propped open using sticks and often collapsed into themselves during heavy wind and wave action. When working with terrestrial amphibians an air pocket above water is necessary, and can be more consistently and safely provided with the PVC pipe frame than by propping bags open with the aforementioned sticks.

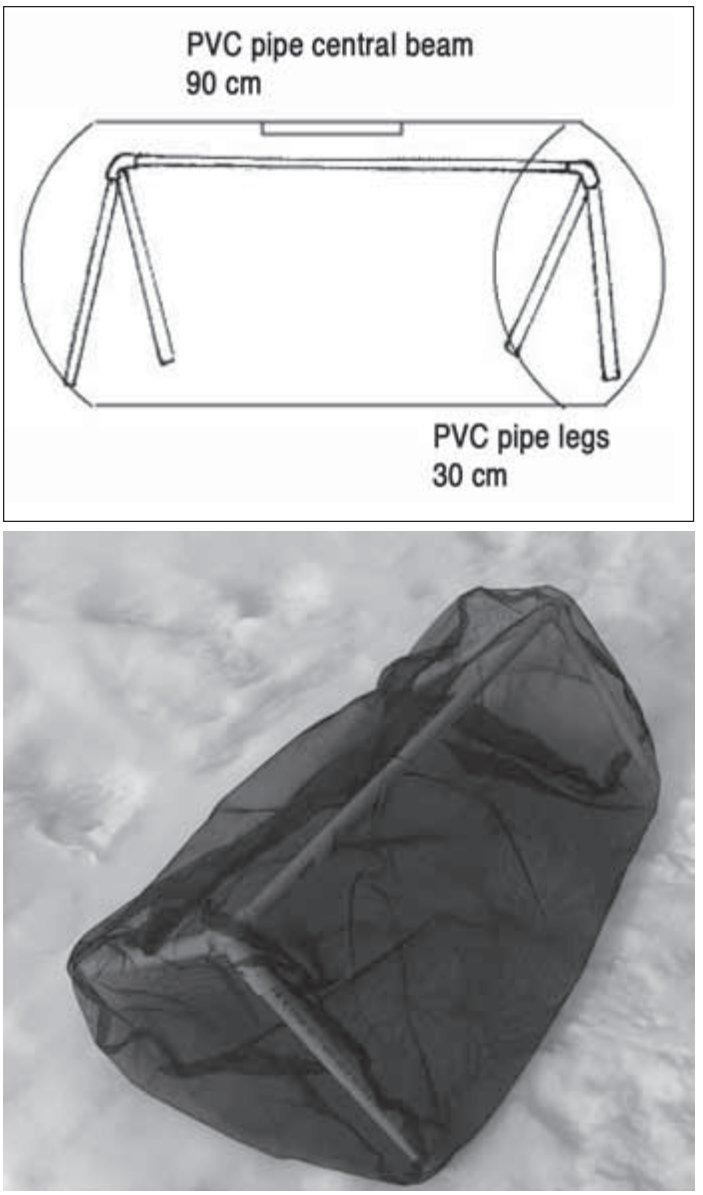

FIG. 1. PVC pipe frame and mesh bag for sampling clutch size. Images are courtesy of Barbara Doyle and Billy Barr.

These cages could be feasibly modified in size for collecting eggs of many different species of salamanders and small anurans, as well as rearing larvae of amphibian species, as has been done with smaller mesh bags and cages (De Solla et al. 2002; Vorndran et al. 2002). Clutch bags can also be used for mating experiments, e.g., to contain a breeding male and female, thereby creating known offspring pedigrees. Additionally, these bags could be used to safely contain predator species when studying the effects of predators on prey behavior in mesocosm experiments.

Materials used to create each bag cost approximately US $6.31. For each frame the budget was as follows: $1.09 for PVC pipe, $2.30 for 3-way elbows and adapters, and $2.92 for screening. Additional funds were spent for the labor to sew bags together; however this could be negligible if the bags were stapled together instead. The low cost, coupled with their versatility, make these bags a suitable and safe alternative to previous methodologies.

Acknowledgments.—This research would not have been possible without funding from the NSF (DEB-0109436 to HW) and Murray State University (Morgan Emery Sisk Memorial Scholarship to JD). We additionally thank Tynes' Upholstery, N. Gerlanc, R. Brown, J. Shaw, S. Wissinger, M. O'Brien, B. Doyle, B. Barr, I. Billick, W. Cowher, C. Priselac, and M. Gansey for support. The experiment complied with the laws of the United States.

Concern over large-scale amphibian and reptile declines and general acknowledgement of sparse baseline information for most herpetological species has prompted the initiation of several monitoring programs. These programs, as well as ecological studies focused on metapopulation dynamics and habitat associations, often use presence-absence (or probability of occupancy) as the parameter of interest. For example, the long-term monitoring design of the US Geological Survey's Amphibian Research and Monitoring Initiative (ARMI) uses multi-season models developed by MacKenzie et al. (2003) to estimate the changes in the proportion of sites occupied by a species. As a national program, ARMI has chosen occupancy as the state variable of interest (rather than abundance), because of the ease and relative cost efficiency of collecting survey data (i.e., detection or non-detection of each target species), and the ability to incorporate the probability of detecting a species to obtain unbiased estimates of occupancy (MacKenzie et al. 2002). Sampling methods may differ in their effectiveness in detecting a species at an occupied site (Bailey et al. 2004). Because a higher probability of detection means fewer surveys are needed to obtain good precision for the occupancy estimator (MacKenzie and Royle 2005), efficient survey designs should consider detection probabilities in the cost/benefit analysis of sampling methods. The goal of this study was to determine the most efficient method for estimating stream salamander habitat occupancy at a regional scale, as part of the Northeast region of the ARMI program (NE ARMI).

Several methods exist for sampling stream salamanders including area-constrained transects (Grant et al. 2005; Heyer et al. 1994), cover-controlled active searches (Heyer et al. 1994; Lowe and Bolger 2002), time-constrained searches (Barr and Babbitt 2002) and leaf litter refugia bags ('leaf litterbags'; Pauley and Little 1998). Area-constrained transect surveys may give a reliable index of the relative abundance of stream salamanders, and multiple passes can be used to estimate population sizes using removal models (Bruce 1995; Jung et al. 2000). Leaf litterbags are a uniform way to sample the leaf litter habitat and are an effective method for determining species presence, but not abundance (Chalmers and Droege 2002; Waldron et al. 2003). Leaf litterbags have been proposed as an appropriate method for determining site occupancy (Pauley and Little 1998; Waldron et al. 2003), and they may increase detection probabilities of some species or life stages.

During a survey, a species can be present but not detected (i.e., a false absence), causing the site to appear unoccupied. To estimate the true occupancy state of a species, multiple 'surveys' are required, which can be in the form of repeat site visits, multiple observers, replicate surveys, or multiple methods conducted simultaneously. Methods that increase detection probabilities of a species can reduce the optimal number of surveys of a site needed to obtain a precise estimate of occupancy (MacKenzie and Royle 2005). To determine the most efficient survey design, we compared the probabilities of detecting *Desmognathus fuscus*, *Eurycea bislineata*, and *Pseudotriton ruber* using area-constrained transects (hereafter 'transects') and leaf litterbags in twenty-five 30 m stream reaches within 12 first- and second-order streams in the Chesapeake & Ohio Canal National Historic Park, Maryland (38°59'N, 77°14'W) and Rock Creek National Park, District of Columbia (38°57'N, 77°02'W). We surveyed each site twice from 16 June to 29 July 2005. During the sample period, all age classes of *E. bislineata* and *P. ruber* were available for capture, while only adult and juvenile *D. fuscus* were available (as the previous year's larvae had metamorphosed by this time). By sampling with both methods within the same stream reach, we were able to estimate detection probabilities for each species-method combination, and determine the possible bias associated with each sampling method.

Methods.—The transects consisted of two 15 × 3 m areas (1 m in the water and 2 m on the bank), located on opposite banks and separated by 15 m. To survey each transect, one observer proceeded upstream, turning all cover objects greater than 6 cm in diameter. An aquarium net was used to facilitate the capture of salamanders. Three leaf litterbags were placed within each 15 m transect at 0, 7.5, and 15 m. The bags were placed one week prior to sampling to allow colonization by salamanders. Our leaf litterbags were constructed of two layers of 50 × 50 cm Deer Block brand plastic netting, with a mesh size of 15 × 15 mm, and filled with 50-60 grams (dry weight) of leaf litter (Chalmers and Droege 2002; Waldron et al. 2003). To maximize the likelihood of capturing larval salamanders, leaf litterbags were partially submerged (Waldron et al. 2003), using a rock to hold each bag in place. The leaf litterbags were checked after a week and again 3–4 weeks later by placing a net under the bag, and immediately placing the bag into a wash basin with water. We shook the bag in water for 15–20 seconds to loosen salamanders, then drained the contents of the basin into a net, and searched for salamanders.

We defined a site as a 30 m stream reach and used the program PRESENCE (MacKenzie et al. 2002) to estimate the proportion of sites that were occupied. For each of the following analyses we used the detection/non-detection data for each species separately, and estimated the species-specific detection probability (*p;* defined as the probability of detecting the species at an occupied site) and the proportion of sites occupied (ψ), while accounting for a species not always being detected when present (i.e., $p < 1$).

We conducted three separate analyses. First, we combined detection information from transect and leaf litterbag searches into a single survey event ('combined' dataset). In this dataset, the probability of detection represents the likelihood that the species was detected by either survey method during a survey event, and the resulting estimate of occupancy should provide an unbiased esti-

Table 1. Detection probability (*p)* and estimates of site occupancy (ψ) for the salamanders *Desmognathus fuscus*, *Eurycea bislineata*, and *Pseudotriton ruber*. The data was analyzed in three ways: using method as a covariate ('Method-covariate'), separately for each method ('Method-specific'), and combined detections from both methods for each survey event ('Combined'). Naïve occupancy estimates for *E. bislineata* (ψ = 0.68), *D. fuscus* (ψ = 0.44) and *P. ruber* (ψ = 0.28) do not account for missed detections. Occupancy could not be estimated for *D. fuscus* under the method-specific leaf litterbag model because there were too few detections for parameter estimation.

		Eurycea bislineata		*Desmognathus fuscus*		*Pseudotriton ruber*

Leaf litterbag	Method-covariate	0.5078 (0.0879)	0.7153 (0.0992)	0.1311 (0.0711)	0.4602 (0.1052)	0.2255 (0.2979)	0.5412 (0.2979)
	Method-specific	0.5476 (0.1410)	0.6669 (0.1678)	0.0612 (0.0342)	—	0.3282 (0.2465)	0.3713 (0.2699)
Both methods	Combined	0.8204 (0.0781)	0.7131 (0.1001)	0.8377 (0.0919)	0.4560 (0.1040)	0.4383 (0.2059)	0.4164 (0.1949)

mate of the true occupancy state of the site. Second, we analyzed a single dataset in which each detection/non-detection observation was separate for the two methods employed during a survey event ('method-covariate'). By modeling "method" as a covariate in the PRESENCE models, we were able to obtain detection estimates for each survey method, using knowledge of sites where the species was detected by the other method. Finally, we analyzed separate datasets ('method-specific') for each method, in which the probability of detection represents the likelihood that the species was detected by only one method. This dataset represents the data that would be collected if only one method was implemented, and thus may reveal a potentially biased estimate of the site occupancy, suggesting that the sampling method itself may be flawed.

These analyses allowed us to investigate possible heterogeneity in detection probabilities caused by sampling bias associated with each survey method. The two methods may differ in their detection probabilities, but if the methods are able to detect a species, then the detection-adjusted estimates of occupancy should be the same among all the analyses. Drastic differences in the occupancy estimates would suggest a bias in the actual sampling method (i.e., if one method was unable to detect, or had very low probability of detecting the target species at occupied sites). Comparing the method-specific estimates of occupancy with the 'method-covariate' and 'combined' datasets gives an assessment of sampling bias for each survey method (Bailey et al. 2004).

Results and Discussion.—For *D. fuscus* and *E. bislineata*, the detection probabilities were higher for transects than leaf litterbags (Table 1). For *D. fuscus* this was expected, because submerged leaf litterbags target the larval life stage (Waldron et al. 2003), which was not present during the survey period. We were therefore unable to estimate a method-specific estimate for leaf litterbags for *D. fuscus* (Table 1). For *E. bislineata* the probability of detection increased slightly when both methods were used. Both methods appear suitable for detecting this species, as the point estimates of site occupancy were similar across all datasets, though transects alone had a slightly higher probability of detection (Table 1). For both *D. fuscus* and *E. bislineata*, incorporating detection probability resulted in an estimate of occupancy that was higher than the naïve estimate (the fraction of sites where the species was detected without accounting for missed detections; naïve $\psi_{E.\ bislineata}$ = 0.68; naïve $\psi_{D.\ fuscus}$ = 0.44, Table 1).

For *P. ruber*, leaf litterbags were more effective at detecting salamanders than area constrained transects (Table 1). Using transects, *P. ruber* was detected at 2 of the 25 sites, and at one site it was found during both survey events. This resulted in a high estimate of *p*, (though with a large SE) for the method-specific transect dataset. However, when method is modeled as a covariate (Table 1; method-covariate dataset), additional information is provided from leaf litterbag detections, which were more efficient at detecting larval salamanders. Including detections from leaf litterbags reduced the estimate of *p* for the transect method (as *P. ruber* was never detected by both methods at a site). The estimate of occupancy for the method-specific dataset using transects was much lower than the known, naïve estimate of site occupancy (method-specific ψ = 0.09, naïve ψ = 0.28). These data indicate the bias in occupancy estimates which would have resulted from using only the transect sampling method, due to the very low probabilities of detecting *P. ruber* (i.e., *p* = 0.1127 for the transect survey method in the 'method-covariate' dataset). For this species, sampling with leaf litterbags in combination with transects increases the detection probability, eliminates or reduces bias in occupancy estimates that may result from using just one detection method, and also decreases the number of times a site should be visited to obtain an optimal occupancy estimate (i.e., low SE) from 19 to 4 visits (MacKenzie and Royle 2005; Table 2).

As expected, using two methods to detect the presence of a species provides a more precise estimate of occupancy than a single method alone (Table 1). For example, *P. ruber* was never detected by both methods at the same site, and the estimate of occupancy is more precise for the combined dataset (Table 1).

If one method is superior for detecting a species, then the addition of a second method provides redundant information that does not improve the occupancy estimate. The inferior sampling method can still be used, but the optimal number of visits to a site increases substantially (e.g., Table 1, 2; leaf litterbags are less suitable for detection of *D. fuscus*, and therefore inflate the optimal number of surveys from k = 2 to 17, MacKenzie and Royle 2005). Further, when the detection probability is high, the increase in detection provided by a second method does not change the esti-

mate of occupancy or the optimal number of visits to a site (e.g., Table 1, 2; *E. bislineata*).

Sampling methodologies may vary in their effectiveness of sampling different life stages. Leaf litterbags are designed to preferentially capture larval salamanders (Waldron et al. 2003), and our transect surveys are designed to sample all life stages. In our study, leaf litterbags detected adult salamanders of all three species with low probabilities, and thus leaf litterbags are not likely to provide the data necessary to estimate patterns in stream occupancy by adult salamanders with sufficient power. If occupancy of a habitat by a particular life stage is of primary interest, then the sampling program should be designed primarily using methods that target that life stage. Regardless, interpretation of results should consider that a sampling method may detect all life stages, while having different detection probabilities for each life stage.

Conclusions.—In studies designed to assess the status and trends in occupancy of a suite of species across a large area, the allocation of survey effort is a chief concern. For species that are difficult to detect on a given sampling occasion, such as *P. ruber*, the use of an additional method may increase the precision and decrease bias in estimates of occupancy. However, since we found leaf litterbags were expensive to construct (materials cost per bag was US $2.50), difficult to maintain in the field, and had lethal effects on non-target organisms (i.e., two dead snakes were found tangled in the litterbags), we suggest sampling the leaf litter at a set distance interval (i.e., 1 m) using an aquarium net, rather than deploy leaf litterbags. Incorporating leaf litter sampling into the transect surveys may be more effective than using leaf litterbags because of increased detections of species that are more likely to be captured within the leaf litter (Bruce 2003; E. Grant, unpubl. data).

Regardless, when designing a research or monitoring program, assessment of the potential bias in survey methods should be incorporated into the study design (e.g., this study; Bailey et al. 2004; O'Connell et al. 2006). In addition, pilot data can guide optimization of data collection to meet a variety of study objectives (Bailey et al. *in press*; MacKenzie and Royle 2005), and will ultimately yield estimates that facilitate comparisons among studies, provided the state variable estimates account for missed detections.

Acknowledgements.—K. Ferebee, B. Yeaman, and M. Frias-Sauter provided their valuable knowledge as biologists at the National Parks. All research was conducted under Maryland State Permit # 4086, Rock Creek Park Permit # 2004-SCI-0012, C&O Canal NHP permit # 2004-SCI-0004, and was approved by the University of Maryland IACUC (protocol R-05-41) and the Patuxent Wildlife Research Center ACUC. Our manuscript was greatly improved by comments from L. Bailey and an anonymous reviewer. The National Park Service's National Capital Region Network and the Northeast Amphibian Research and Monitoring Initiative of the United States Geological Survey provided funding for this project. A New Method for Estimating Clutch Sizes of Ambystomatid Salamanders and Ranid Frogs: Introducing the Ovagram

NANCY E. KARRAKER*

Clutch size is an important demographic trait of amphibians that is frequently used in descriptive ecological studies (Woodward 1982), biogeographic comparisons (Karraker et al. 2006), studies of population dynamics (Berven 1990) and population modeling (Vonesh and De la Cruz 2002). However, egg masses are large in many species, and clutch size cannot be easily determined visually in the field because embryos in the interior of the mass are obscured. In these instances, determination of clutch size often requires breaking clutches apart which can subject interior embryos to changes in temperature, predation, and microbial attack. Thus, it is important to develop techniques that permit collection of reliable clutch size data while minimizing impacts on study organisms.

Several methods have been used to estimate clutch sizes in Spotted Salamanders (*Ambystoma maculatum*) and Wood Frogs (*Rana sylvatica*), including direct counts of embryos (Berven 1982, Brodman 1995), visual estimation (Stenhouse 1987), photographic analysis (Harris 1980), regression estimation from dry weight (Howard and Kluge 1985), and dissection (Woodward 1982). Clutch sizes of *A. maculatum* were also determined by flattening egg masses beneath a glass plate and counting the embryos (Harris 1980). To my knowledge, none of these estimation techniques were assessed for accuracy.

Here I describe the construction and use of the "ovagram," a non-destructive device to quickly estimate clutch sizes of ambystomatid salamanders and ranid frogs. This improves on Harris's (1980) method of flattening egg masses of *A. maculatum* with a glass plate in being a lightweight, inexpensive device that is easily transported to remote locations, and the addition of grid lines increases ease of counting and probably accuracy. The ovagram is the first reported method, to my knowledge, of clutch size estimation for a ranid frog by flattening egg masses beneath a clear object. I provide results of an assessment of the ovagram's accuracy in estimating clutch sizes in *A. maculatum* and *Rana sylvatica*, and its impacts on hatching success in *A. maculatum*.

Materials and Methods.—The ovagram was constructed using two circular, 1400 ml plastic, reusable food storage containers. These containers were made of thin, clear plastic and are commonly available in supermarkets. The dimensions of the containers were as follows: top diameter 17 cm; bottom diameter 14.5 cm; circumference 53.4 cm; depth 8.5 cm. I drew a series of parallel lines, 1 cm apart, using a fine-point permanent marker, across the entire underside of one container (Fig. 1). Lines must be narrower than embryos so that embryos falling directly beneath the lines can be detected. To use the ovagram, an egg mass of *A. maculatum* was gently removed from the water and placed in the container without lines. The container with lines was placed on top of the egg mass inside the other container and pressure was gently applied to flatten the egg mass (Fig. 1). The amount of pressure applied was not great enough to physically damage the ova or the outer jelly matrix. Counts were made in a systematic pattern, for example left to right and top to bottom, counting the number of embryos intersecting the first line, then in the space between the first and second lines, and so on (Fig. 1). A similar method was used for clutches of *R. sylvatica*, except that clutches were cut into six, approximately equal-sized pieces with a sharp knife and counts were made for each piece separately. The ovagram can be used at any stage prior to hatching, but counts are more easily obtained from recently oviposited egg masses that are less turgid and smaller in size. For clutches of *R. sylvatica*, fewer embryos were damaged when cutting recently laid clutches. Estimates were made in approximately 10–20 s for *A. maculatum* and 2–3 minutes for *R. sylvatica*. Following estimation, clutches were returned to the water, and an attempt was made to return the egg mass to its original attachment point at the water depth from which it was taken.

The ovagram was used to estimate clutch sizes of 277 egg masses of *A. maculatum* from 30 ponds, and 116 clutches of *R. sylvatica* from 24 ponds in the Adirondack region of New York. It is important to note that female *A. maculatum* generally deposit 2–4 egg masses at breeding (Bishop 1941; Shoop 1974), so clutch size here refers to the number of eggs per egg mass and not the full egg complement. *Rana sylvatica* deposit one egg mass or clutch in a given breeding season (Wright and Wright 1949).

FIG. 1. Photograph (top view) of ovagram containing an egg mass of *Ambystoma maculatum* and showing parallel lines used to count embryos. Note that width of each line is narrower than that of each embryo.

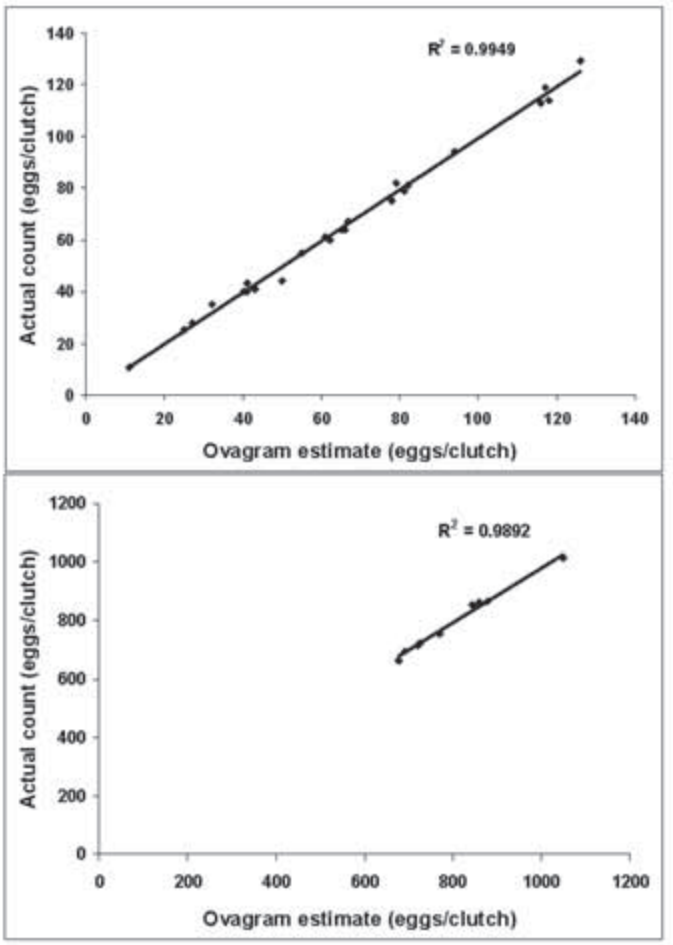

FIG 2. Relationship between estimates of clutch size using the ovagram and actual counts of 24 clutches from *A. maculatum* and 10 clutches from *R. sylvatica*.

To determine the accuracy of clutch size estimates using the ovagram, I collected 24 egg masses of *A. maculatum* from two vernal pools and 10 egg masses of *R. sylvatica* from two vernal pools in the same region. I estimated clutch size using the ovagram and then gently dissected each egg mass into easily counted sections containing 1–4 embryos each. I counted the number of embryos in the dissected portions twice for each egg mass, to ensure accurate counts. To determine the impacts of use of the ovagram on egg masses of *A. maculatum*, I compared the hatching success of embryos from egg masses manipulated by the ovagram and those not manipulated.

Results.—Average clutch size of *A. maculatum* in the central Adirondack region of New York estimated with the ovagram was 67.2 (SD = 30.5, N = 277) and clutch sizes ranged from 7–155. Mean clutch size of *R. sylvatica* was 682.4 (SD = 118.2, N = 116) and ranged from 429–1049 eggs per clutch.

In the accuracy assessment, the mean absolute difference between ovagram estimate and actual count for *A. maculatum* was 1.7 embryos (SD = 1.6, N = 24) and for *R. sylvatica* was 11.3 embryos (SD = 10.6, N = 10). In *A. maculatum*, seven of 24 ovagram estimates matched the actual counts (including four clutches that had more than 50 embryos each), 11 were overestimates (largest = 6 embryos), and 6 were underestimates (largest underestimate = 3 embryos). In *R. sylvatica*, 8 of 10 counts were overestimates (largest = 11) and 2 were underestimates (largest = 37). Clutch sizes of *A. maculatum* estimated using the ovagram averaged 65.7 embryos (SD = 31.8, range 11–126) and were comparable to actual counts which averaged 65.2 embryos (SD = 31.7, range 11–129) for the 24 egg masses evaluated in the accuracy assessment (Fig. 2). Similarly, in *R. sylvatica*, ovagram estimates averaging 798.9 embryos (SD = 107.7, range 662–1012) were comparable to actual counts which averaged 807.8 embryos (SD = 113.6, range 678–1049) (Fig. 2).

The ovagram was used to estimate clutch size in *A. maculatum* in a laboratory experiment, where survival to hatching averaged 83% (SD = 10; N = 5) in control (exposed only to filtered water) egg masses. Survival averaged 82% (SD = 17; N = 17) in egg masses not exposed to the ovagram and used as controls in another experiment (Karraker and Gibbs, in prep.), suggesting that survival of embryos to hatching was not compromised by the technique. I did not determine survival to hatching in clutches of *R. sylvatica* following use of the ovagram.

Discussion.—Variation in clutch size in this study was pronounced, ranging from at least 7–155 in *A. maculatum* and 429–1049 in *R. sylvatica*, emphasizing the need for accurate clutch size estimation for biological studies of these species. A number of other methods have been used previously to estimate clutch size in these amphibians. Egg masses have been marked in the field and frequent visits made to each clutch to monitor development. In one study (Brodman 1995), as the first larvae began hatching, all live and dead embryos were counted. Estimates using this method, as well as visual estimation at any time in the developmental period (Stenhouse 1987), may under- or overestimate clutch size because of the difficulties associated with counting interior embryos. Predation by caddisfly larvae (Stout et al. 1992) during development may also make accurate counts difficult. In addition, multiple visits must be made to egg masses, particularly as embryos near hatching, making it more difficult to obtain larger sample sizes. Female *A. maculatum* have been collected, euthanized, and dissected to determine clutch size (Woodward 1982), but this method, depending upon the numbers collected, may be detrimental to local populations. Egg masses have been photographed and embryos counted using gridded oculars on a dissecting scope (Harris 1980). This technique is minimally invasive, but if a photograph is taken from one perspective, an embryo directly in line with another may not be counted and the method can be cumbersome and protracted relative to the ovagram method described herein. Harris (1980) also flattened egg masses beneath a glass plate in a plastic tub and counted embryos, a method similar to the ovagram. However, the lines on the ovagram may improve accuracy, and the ovagram is small, lightweight, and inexpensive.

The ovagram can be used to accurately estimate clutch sizes of *A. maculatum* and *R. sylvatica*, and probably other ambystomatid salamanders and some ranid frogs, causing minimal physical damage to egg masses and without reducing survival of embryos in *A maculatum*. As all egg masses of *A. maculatum* examined in this study were clear, future research should test the efficacy of the ovagram on opaque eggs of *A. maculatum* and on the eggs of other species. To expedite counts, this method could be coupled with digital photography and an image processing and analysis pro-

gram that counts discrete objects in an image, such as has been used to measure compactness of substrates in nests of fish (Candolin and Salesto 2006). This would reduce time in the field and bias, if multiple observers are involved.

Acknowledgments.—Thanks to Jeff Alvarez, James Gibbs, Clara Wheeler, and Chris Phillips for helpful comments on previous drafts of this manuscript, and Geri Tierney for useful discussion. I am grateful for the financial support of the Declining Amphibian Populations Task Force, USGS Amphibian Research and Monitoring Initiative, and the U.S. Environmental Protection Agency (GRO Fellowship). This study was conducted in compliance with all applicable institutional animal care guidelines, and with all required state and federal permits.

An Alternative Method for Restraining Frogs

RYAN M. BOURQUE
Department of Biological Sciences, Humboldt State University
Arcata, California 95521, USA
e-mail: rmb32@humboldt.edu
e-mail: rbourquex@hotmail.com

Herpetologists use several different methods for marking adult anurans to study their natural history and ecology. Some techniques include toe-clipping, passive integrated transponder (PIT) tags, visible implant elastomer (VIE), and radio transmitters (Donnelly et al. 1994). Employing these techniques requires maintaining control of study animals, which often requires additional personnel or the use of anesthetics (e.g., MS-222). These methods of restraint are often expensive and anesthetics require recovery time and may have lasting effects on an animal. Several devices have been designed for restraining herpetofauna (Hoefer et al. 2003; Jones and Hayes-Odum 1994; Poulin and Ivanyi 2003; Quinn and Jones 1974; Walston and Mullin 2005), however, only two methods have previously been described for restraining anurans (Christy 1998; Heyer et al. 1994). While effective, these methods are either useful with a specific marking method (e.g., PIT tags) or are overly complicated and have limited durability. Consequently, there is a need for an inexpensive and more efficient means of restraining anurans to be marked. Here I present a new device for restraining anurans being fitted with radio transmitters or marked using other techniques (e.g., PIT tags and VIE) that is inexpensive, durable, waterproof, easy to use and decontaminate, lightweight, and restrains frogs safely and quickly.

The device has five basic components: the base plate, the compression plate, two anchor bolts, two compression locks, and two compression pads (Fig. 1). The base plate is a 240 × 90 × 6 mm piece of clear Plexiglas® with a pair of countersunk and threaded 4 mm holes. Each hole is positioned 8 cm from one short edge and 1 cm in from each long edge. The compression plate, also constructed of clear Plexiglas® (90 × 25 × 6 mm), has two 6 mm holes centered along its width that align with the holes in the base plate. The two anchor bolts are 4 mm fine-thread stainless steel bolts screwed into the base plate. The compression pads are two pieces of weather stripping (PVC closed cell foam, 6 × 9 × 9.5 mm), which can be purchased at most hardware stores. This material is soft and forms to the contours of the frog's hind legs without damaging the skin. The two compression locks are plastic cord locks commonly used on backpacks and stuff sacks and are available for purchase at most camping stores. All components (~ US $7.00) are durable and easy to decontaminate when moving between study sites.

Restraining frogs is simple, quick, and effective. With hind legs extended, the frog is positioned ventral side down on the base plate with the knees centered on the base plate compression pad (Fig. 2). The positioning of the frog on the device is important because controlling the knees inhibits movement of the hind legs and prevents injury to the frog. The compression plate is then slid over the anchor bolts and appropriate pressure is applied to prevent the frog's legs from moving. The cord locks are then slid

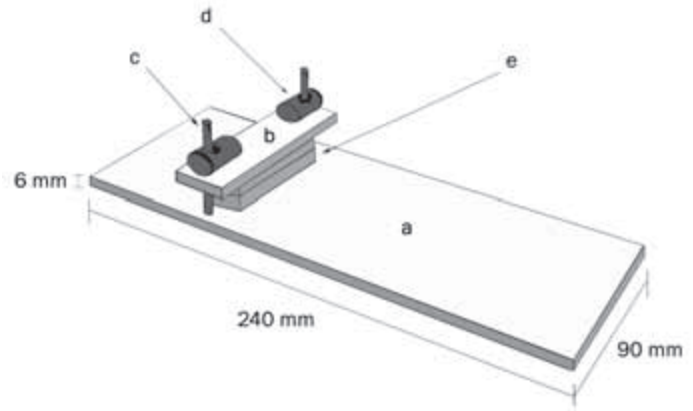

FIG. 1. The five basic components of the anuran restraining device: a) base plate; b) compression plate; c) two anchor bolts; d) two compression locks; and e) two compression pads.

over the anchor bolts and locked against the compression plate. Spinning the cord locks clockwise or counter clockwise allows fine-tuning of the pressure exerted on the frog. Care must be taken to avoid exerting excessive force, which could restrict blood flow. The amount of time required to restrain a frog using this device is approximately 15–30 seconds.

I have found this device to be invaluable when working alone and marking small to medium-sized ranid frogs (30–90 mm snout–urostyle length, SUL). To date it has been used to effectively restrain Foothill Yellow-legged Frogs (*Rana boylii*, N = 150 [R. Bourque, unpubl. data and C. Wheeler, pers. comm.]), Cascades Frogs (*Rana cascadae*, N = 711 [J. Garwood, pers. comm.]), and Mountain Yellow-legged Frogs (*Rana muscosa*, N = 15 [J. Bettaso, pers. comm.]) during PIT tag implantation, radio transmitter attachment, and/or toe clipping. I have also found this device to be effective for restraining Bullfrogs (*Rana catesbeiana*, N = 5), Pacific Treefrogs (*Hyla regilla*, N = 5), Northern Red-legged Frogs (*Rana aurora*, N = 5), and Coastal Tailed Frogs (*Ascaphus truei*, N = 5). Restraint of larger frogs (> 90 mm SUL) would require constructing a larger version of the device described here. Of approximately 148 individual frogs of three species (*R. boylii*, *R. cascadae*, *and R. muscosa*) that were restrained using this device and studied using radio telemetry for relatively long time periods (28–112 days), no visible ill effects were observed resulting from restraint. Lastly, this device has reduced handling time, and thus minimized the amount of stress experienced by the frog during marking procedures.

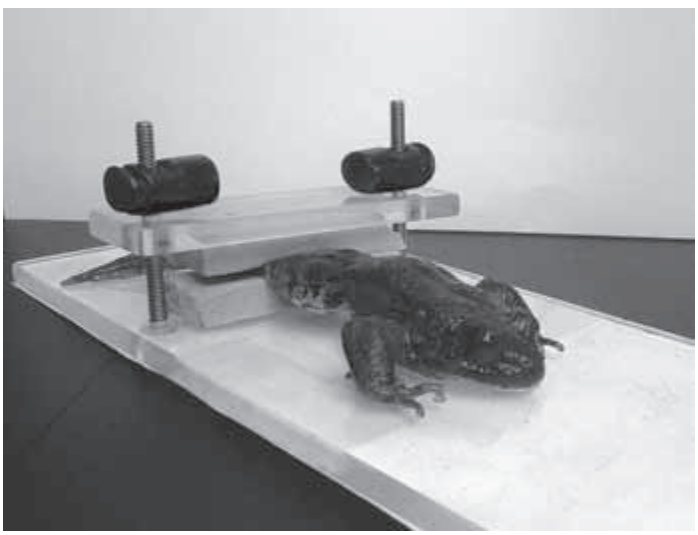

FIG. 2. Proper restraint of a frog (*Rana boylii*) with knees centered on the compression pads and immobilized using appropriate pressure, which is maintained by cord locks.

Acknowledgments.—I thank Bill Burrows, Marty Reed, Lewis McCrigler, and Don Ashton for their expertise and assistance during the development and construction of this device. I also thank Jamie Bettaso, Melissa Dean, Justin Garwood, Sharyn Marks, and Clara Wheeler for their encouragement, support, and valuable comments on earlier drafts of this manuscript. Humboldt State University Institutional Animal Care and Use Committee (log number 03/04.B.34.A) has approved this device and the required scientific collecting permit was obtained from the California Department of Fish and Game (permit number 803018-03).

The Gopher Tortoise (*Gopherus polyphemus*) is a large fossorial chelonian, averaging 23–28 cm in carapace length, that constructs extensive underground burrows in pyrogenic ecosystems of the southeastern US, especially favoring the sandhill and scrub vegetative communities (Auffenberg and Franz 1982; Diemer 1992). Because an entire community of at least 362 species of vertebrates and invertebrates use these burrows at some stage in their life or seasonal cycle (Jackson and Milstrey 1989), the Gopher Tortoise has been referred to as a keystone species (Eisenberg 1983). Gopher Tortoise burrows vary in diameter, depth, and complexity and play a critical role in the ecological processes of sandhill and scrub communities of Florida. They impact geomorphology (Butler 1995), soil dynamics (Gardner and Landers 1981), vegetation patterns (Kaczor and Hartnett 1990; Tuberville, 1998), animal community diversity (Milstrey 1987 for invertebrates, Franz 1986 for vertebrates), and possibly hydrology, at scales ranging from microsites to landscapes. Some species, such as Florida Mice (*Podomys floridanus;* Jones and Franz 1990), Eastern Cottontail Rabbits (*Sylvilagus floridanus;* Kinlaw 1999), and Armadillo (*Dasypus novemcinctus*; Guyer and Hermann 1997), will modify tortoise burrows for their own needs, adding complexity over time. Gopher Tortoise populations currently are in decline throughout the species' range (Auffenberg and Franz 1982; Diemer 1986; Estes and Mann 1996). The Florida Fish and Wildlife Commission (FWC) is currently reclassifying the tortoise from its present status as a 'Species of Special Concern' (FWC 2004) to a Threatened status (FWC 2006a), along with strengthening protection of its burrows (FWC 2006b).

Data on the internal geometry of a burrow can be obtained using simple measurement tools such as calipers, calibrated flexible rods, or by measuring dimensions of casts of burrows made from hardening agents. In the southeastern US, Gopher Tortoises are collected on sites slated for development by excavating their burrows using heavy equipment (Blankenship and Thomas 2005). Although general information about the depth and extent of burrows can be learned by this method, it destroys burrows, along with any opportunity for repeat measurements of burrow geometry. With excavation, any beneficial ecological effects of the destroyed burrow are lost. Invasive probing methods can cause burrow abandonment or behavioral disruption of the burrow inhabitants (A. Kinlaw, pers. obs.). Some success in understanding underground burrow structure for other animals has been achieved in the UK using geophysical methods. Butler et al. (1994) were successful in determining size for six badger (*Meles meles*) setts using soil resistivity but were unsuccessful using magnetmometry. Any approach to modeling changes of burrow structure over time, such as Meadow's (1991) model, which is based on tortuosity and complexity, requires a method to image burrows that is non-invasive, repeatable, and relatively quick.

Ground penetrating radar methodology.—Ground penetrating radar (GPR) is a non-invasive subsurface imaging technology which uses a surface antenna to transmit electromagnetic energy pulses in the form of radar waves, downward into the ground (Conyers 2004). Waves of varying amplitudes are then reflected back from buried interfaces to a receiving antenna, which is assembled together with the transmitting antennae on a movable sled or cart. The time elapsed between transmission and reception, the amplitude and phase of the received waves, and the frequency of those waves are recorded on the hard drive of a computer which interfaces with the antennas. Of the waves reflected back from buried interfaces, the largest amounts of energy are reflected back from highly contrasting media. In the case of air-filled burrows, a good deal of radar energy is reflected from the interface between the sandy sediment and the void of the burrow itself; other reflections can occur from tree roots, shallower burrows of other animals and sedimentary or soil beds. As the sled is slowly moved along pre-determined surface transects, a series of reflections can be collected at a programmed distance, determined by the revolutions of a survey wheel attached to the sled (Fig. 1A). All reflections are collected in radar travel times measured as two way-travel time in units of nanoseconds. These times can be converted to approximate depth in the ground when the velocity of the radar energy travel is calculated. When many hundreds of these reflections from varying depths are stacked and viewed in a two-dimensional vertical profile, a "cross-section" of the ground is produced.

Radar energy propagation occurs best in dry sandy soils, however good penetration also can occur in a number of other ground conditions (Conyers 2004). The applicability of GPR to locate cavities such as pipes or tunnels was recognized in the 1970s (Fullagar and Livleybrooks 1994). Since air-filled voids provide an excellent dielectric constant contrast (Daniels et al. 1992), GPR is used to identify animal burrows in earthen dams in the United States which might cause collapse of dams (ASDSO 1999).

Field Site Description and Burrow Selection.—Three study sites were located in the Ocala National Forest, Marion County, Florida, USA. The sandhill site (Kerr site) is located along the north shore of Lake Kerr, in the Lake George District of the Forest. The two oak scrub sites were located adjacent to the US Naval Reservation in the Seminole District of the Forest. In Florida, sandhill vegetative communities are rolling park-like woodlands of Longleaf Pines (*Pinus palustris*) rising above a continuous cover of Wiregrass (*Aristida stricta*) with other grasses and forbs, and occasional clumps of deciduous oaks, mostly Turkey Oak (*Quercus laevis*; Myers 1990). Visually, sandhills are open and one can often see for a hundred meters or so. Uncut Sand Pine scrub is a vegetative community of tall, twisted, leaning Sand Pine trees (*Pinus clausa*)

rising above a thick understory of evergreen scrub oaks (*Q. geminata*, *Q. myrtifolia*, *Q. inopina*, *Q. chapmanii*), Florida Rosemary (*Ceratiola ericoides*), interspersed with Rusty Lyonia (*Lyonia ferruginea*), Scrub Holly (*Ilex opaca* var. *arenicola*), Silk Bay (*Persea humilis*), and Scrub Hickory (*Carya floridana*; Myers 1990). However, scrub vegetation often has open areas. Our GPR scrub sites had been logged within 10 years previous to our study, thus the Sand Pine trees were between one and five meters high. The soil type in both sandhill and Sand Pine scrub vegetation is classified as entisols, dominated by gently sloping, well-drained thick sands (Brown et al. 1990). These excessively drained soils are derived from quartz sand (Brown, et al. 1990) and are mostly devoid of silt and clay.

Our plots and burrows were chosen as part of a related research project. Many sandhill plots were available, thus a map of this vegetative community was gridded into one hectare squares and each square assigned a number. The plots were then selected using a random numbers table (Steele and Torie 1980). Gopher tortoises seem to prefer sand pine scrub areas that have undergone succession three to five years after a clear-cut, so the scrub plots were chosen from the few appropriately aged plots available. We tried to select only burrows that appeared to have been recently dug or were actively being used by the tortoises, since the literature indicated that these provided the most biological insight.

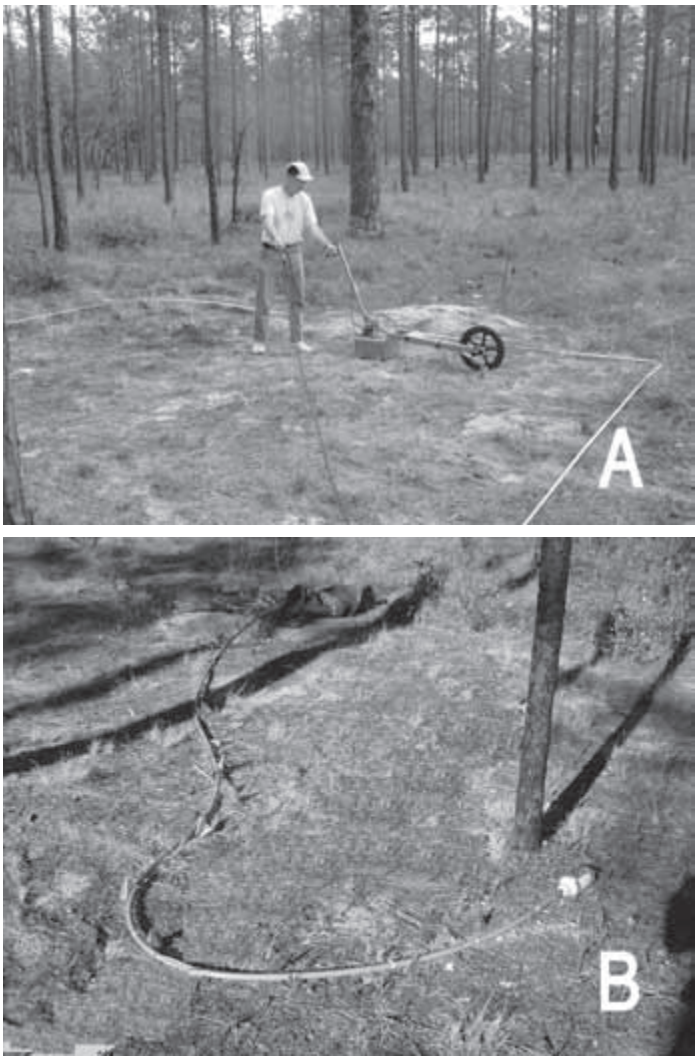

FIG. 1. A) Pulling GPR antenna in perpendicular direction across the long axis of gopher tortoise burrow in sandhills plant community, Ocala National Forest, Florida, USA. Note mound of sand behind antenna, indicating where tortoise piled up sand from digging activities. B) Two-dimensional profile of burrow Kerr6 on ground surface. The path of the burrow is outlined by the line marked by flags and spray paint, with the tube of the video camera also aligned along the path. View is opposite to the digging direction of the tortoise, with the burrow opening at the upper center of photo.

Prior to testing with GPR all burrows were examined with an infrared video probe camera attached to a 7.7 m section of polybutylene tubing (assembled by Edward E. Wester, Southern Ecosystems Research, 6485 Lee Road 54, Auburn, Alabama 36830, USA). This examination found that six of the burrows each contained a tortoise. The length of four others exceeded the length of the camera tether and occupancy could not be confirmed, but recent tracks, skid marks, and other surface signs indicated obvious use within a day or two prior to our testing. Finally, four burrows had sign that was somewhat deteriorated and did not have a resident tortoise (Table 1). Under the current scheme in use in the southeastern US to classify the status of Gopher Tortoise burrows (Auffenburg and Franz 1982), ten would be classified as "active" and four as "inactive."

GPR Collection Procedure.—The GPR antennae at our test sites were first calibrated for ground conditions that were often unique to each area. This included setting automatic range gain settings to enhance the reflection amplitudes with depth due to normal energy attenuation in the ground (Conyers 2004). A time window was selected, measured in nanoseconds, which preliminary velocity tests showed to be consistent with the maximum depth of the burrows. This time window varied between 50 and 70 nanoseconds, which corresponded to a maximum energy penetration depth of about 4–5 m. Optimal energy penetration occurs when the antennae are in direct contact with the ground surface at all times (Conyers 2004). To facilitate this, ca. 20–80 m^2 of vegetation immediately above each burrow was mowed. We then followed a two step procedure to map the burrows in the field. First, each burrow was probed with a piece of flexible electrical conduit to determine its beginning direction and maximum extent. Then, using a 900 MHz frequency antenna (Geophysical Survey Systems, Inc., 13 Klein Drive, PO Box 97, North Salem, New Hampshire 03073-0097, USA), we collected a series of "trial and error" transects at orientations estimated (from the initial probings) to be perpendicular to the burrow. In this way radar reflections when viewed in profile would produce a hyperbolic shaped reflection, with the apex of each hyperbola (Fig. 2A) denoting the top of the burrow tunnel. The location of each hyperbola apex was marked with a pin flag at the ground surface immediately over the section of tunnel that had just been crossed by the GPR antenna. This preliminary process of profile collection and immediate interpretation was continued until an approximate burrow path was delineated by flags, and then its total extent was marked with spray paint. During this preliminary step it was quickly determined that most burrows were not straight, but angled quickly from the surface as they continued down to greater depths. When many reflection profiles were collected in this way and viewed on the computer screen in "real time," the depth and orientation of the burrow void spaces could be determined. Often this process was con-

fusing, as shallower burrow reflections, tree roots and the complex nature of reflections from curving tortoise burrows that often reached three and a half meters in depth produced an array of reflections with many different orientations.

Following Stott (1996), we wanted to verify that the hyperbole reflected by the GPR antenna was in fact the subsurface tortoise burrow we believed we were imaging, not a different burrow, unknown air void, or a sampling artifact. During this pilot step, we confirmed that the GPR antenna was actually imaging the burrow path by examining the section of tunnel directly underneath with the video probe camera slid down the tunnel. By treating the vertical distance between the antenna and the burrow immediately below the antenna as side A of a right triangle, and the horizontal distance between the antenna and the burrow entrance on the ground surface as side B of the triangle, we used the Pythagorean Theorem to calculate the correct distance (hypotenuse) to slide the camera down the burrow to be immediately underneath the antenna. This confirmation step was only conducted near the entrance of the first few burrows we imaged before the burrow curved.

To accurately map the depth of the burrows, we conducted a velocity analysis to calibrate the relationship between radar travel time and depth. At several locations along the first three burrows we processed, a calibrated steel rod was inserted from the ground surface to the top of the burrow; the point of insertion into the burrow could be determined by a relaxation of insertion pressure as it entered the void space. Correct placement of the rod in the burrow chamber was confirmed by observation with the videoprobe camera. These depths were then measured and the elapsed radar time measured in the GPR reflection profile at that location was then obtained. In these tests an average radar travel velocity was calculated to be 8 cm/nanosecond. Using this average velocity a two-way radar travel time of 45 nanoseconds was equivalent to ca. 3.6 m in the ground. This velocity was used to convert all measured times of burrow reflections to depth at all test sites. For all the sites tested this average velocity appeared to be consistent, which is understandable as all the burrows tested were found in the same type of dry aeolian sand. Ground moisture conditions, which can sometimes dramatically change radar velocities, were similar during GPR data acquisition. By following this process, an accurate depth profile of each burrow was made.

In the second step, a rectangular grid was then arranged over the total extent of each burrow with tape measures and their surface extent was mapped as x and y coordinates, measured from the southwest datum of each grid. The GPR antennae were moved in four meter transects perpendicularly across the burrow to collect reflection profiles normal to the orientation of the burrow (Fig. 1a). The middle of the profile (at ca. 2 m) therefore denoted the approximate center of each burrow, no matter what its depth. Reflection transects were placed every 50 cm along each surface-outlined burrow in this second step, which was a more formal process than our preliminary trial and error step. Paint and surveyor flags were used to mark the orientation and extent of each burrow (Fig. 1b), and photographs were taken. In this fashion the x and y coordinates of the burrow were determined from the surface measurements with z values (depth) obtained for each profile by measuring from the surface down to the apex of each reflection hyperbola (Fig. 2a). On each burrow, we made a final longitudinal transect along the ground surface that followed the path of the burrow; the resulting profile illustrated the gradual vertical drop of the burrow as the antenna moved (Fig. 2B).

Image Analysis.—Data points were transferred to two programs which translate three-dimensional spatial data into visual displays. Slicer-Dicer (Pixotec, LLC, 15917 S.E. Fairwood Blvd, Renton, Washington 98058, USA) is a program that allows the user to visualize three-dimensional data as a projected volume. This program creates isosurfaces from the data, meaning that the inter-

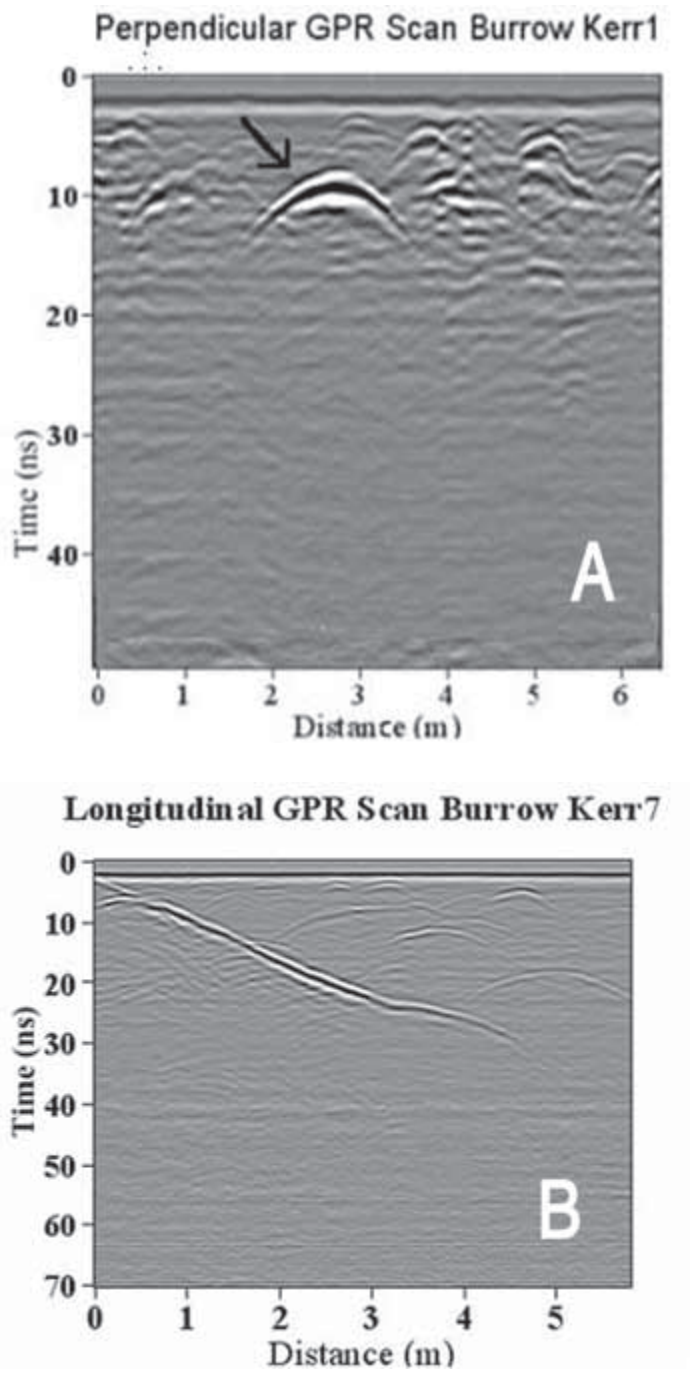

FIG. 2. A) Hyperbole (indicated by arrow) shown in GPR reflection profile, collected by moving the GPR antenna on the ground surface over the burrow at a 90° angle to the orientation of the burrow. B) GPR Longitudinal profile of burrow, collected by moving the GPR antenna on the ground surface following the path of the burrow.

faces producing the GPR reflections are placed in three dimensions, and a pattern or color is assigned to specific amplitudes in order for them to be visible (Heinz and Aigner 2003). The second program, FormZ **(**Auto·des·sys Inc., 2011 Riverside Drive, Columbus, Ohio 43221, USA), is a general-purpose solid and surface modeler with which the user can generate highly articulated renderings of most three-dimensional forms from x, y, and z data. To determine how accurately these renderings describe real burrow geometry, we compared them with physical casts of burrows prepared at a Clermont, Florida site where the burrows were being excavated for relocation purposes, with photos taken during these burrow excavations, and with one literature account.

Results.—The two dimensional outlines on the ground surface showed that nine burrows turned to the left within two to three meters of their opening, three turned right, and one was fairly straight (Table 1). Data were incomplete for one burrow which had collapsed about three m from the entrance. A 3-dimensional profile was developed for one burrow using the Slicer-Dicer visualization program, showing a downward corkscrew turn to the left (Fig. 3A). Three-dimensional profiles were developed for four burrows using the FormZ modeling program, which showed the burrow tunnels had smooth sides, some up and down loops or twists, and an overall "jagged" corkscrew shape (Fig. 3B). Examinations of hardened foam burrow casts and photos from the Clermont relocation site confirmed that those burrows had the same properties.

Discussion.—This research provided the first intact visual views of gopher tortoise burrows. The two-dimensional outlines on the ground surface show that most burrows investigated in this study turn in some fashion. The three-dimensional profile showing a corkscrew shape coincides with observations by Smith et al. (2005) for burrows that were excavated during a drought in east-central Florida. They reported burrows which angled down in a corkscrew fashion and attributed this to tortoises digging until they reached a cool hardpan layer under sand during the drought. Moreover, our comparison with the appearance and orientation of the FormZ three-dimensional renderings with actual hardened foam casts of burrows indicates that the models developed with this program accurately compares with the orientation and shape, including turns, of real burrows. Since the resolution of the GPR system we used was not detailed enough to image smaller side tunnels or rough surfaces along the side of the main tunnel, these features would not be represented in the visualization programs. Although the FormZ program smoothes the surface of a tunnel, this did not affect our results, as our burrow casts show fairly smooth surface features. These foam casts were taken in an area without shrubs or trees; we caution that the sides of burrows occurring in areas with more roots may not be as smooth. The longitudinal GPR profiles produced at each site clearly show burrows descending into the ground, sometimes leveling out, and again descending to their end. The FormZ models illustrate well both the up and down undulations of the burrows, as well as the turns, and the foam casts confirmed that these features occur in real burrows. All bio-mathematical models are approximations, and there is no reason why our three-dimensional renderings of burrows should be different. Thus, comparisons with features of real burrows show that these visualization programs using GPR data do provide reasonable models of burrows.

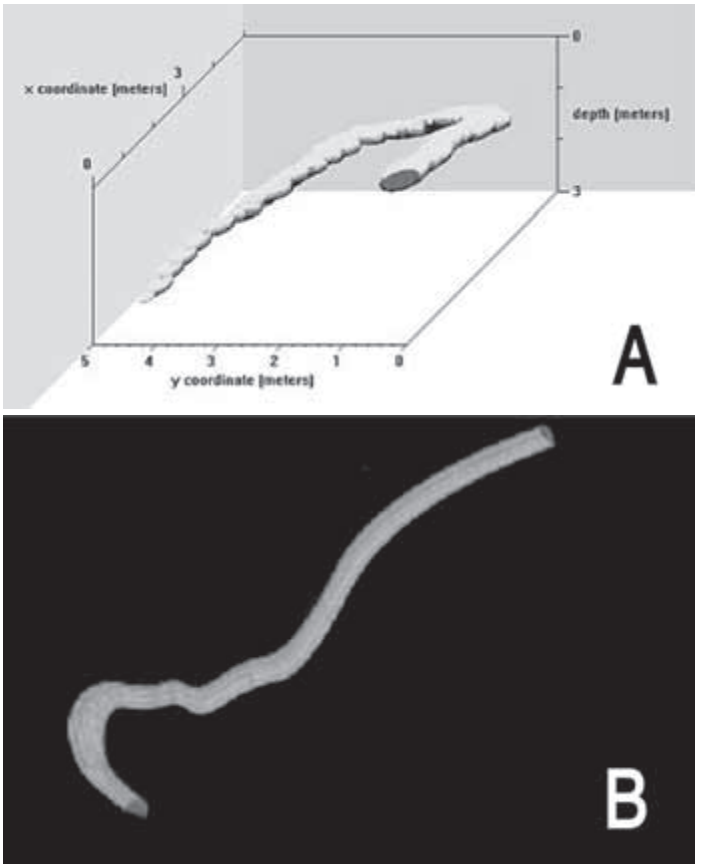

FIG. 3. A) Three-dimensional image of burrow Kerr3 developed using the Slicer-Dicer isosurface modeling program. B) Black on white three-dimensional rendering of burrow Kerr6 developed with the FormZ program.

Ground penetrating radar can assist with practical conservation efforts of the Gopher Tortoise. Gopher tortoises occur in a number of national forests and military reservations throughout the southeast. GPR could be used to assess or estimate the damage caused by heavy equipment, such as forestry skidders or military tanks, which can cause the collapse of burrow entrances. Gopher tortoises will also dig burrows in suitable soil occurring on cattle ranches. Trampling by cattle can collapse the opening or shallower sections of burrows, especially in overgrazed areas (A. Kinlaw, pers. obs.). The single collapsed burrow (NE2) found in this study was encountered very early in our study and we did not attempt to thoroughly map it. However, our subsequent mappings demonstrated that intact tortoise burrows could be imaged even if the entrance was completely sealed, because our GPR ground profiles showed other burrows underground (near our imaged burrows) that could be traced to old soil mounds.

By imaging the internal architecture of burrows, GPR technology could clarify issues relating to energy expenditure in building the burrows, flooding of burrows, respiratory environment, and amount of living space for invertebrates and commensal vertebrates. By collecting a time series of profiles at the same burrow, changes in the architecture of a burrow can be better understood, as well as changes in architecture brought about by other animals that modify a burrow.

There are many advantages of using GPR for mapping and vi-

TABLE 1. Data for Gopher Tortoise burrow study collected without and with ground penetrating radar.

	Data gathered before use of GPR			Additional data gathered with GPR			
Burrow Number	Habitat	Length Probed (m)	Tortoise Present?	Beginning Direction	Ending Direction	Configuration	Maximum Depth (m)

[c] Burrow extends beyond length of camera; gopher tortoise probably residing in burrow based on recent tracks and sign

sualization of burrows. Like any good scientific method, GPR mapping is repeatable. A major advantage is its non-destructive abilities. Although the environmental impact of mowing a small amount of vegetation at the surface immediately above a burrow is not known, none of the burrows or entrances was physically impacted in any way using this technique. The method is non-invasive to the interior of the burrow; all the work is done at the surface. Finally, the digital format allows the data to be analyzed using a variety of approaches.

Presently the only other method available to obtain an image of a burrow is to fill a burrow with some type of material that hardens into a three-dimensional mold of the burrow shape, then excavate the mold. Although excavations are normally conducted to relocate gopher tortoises, it can be part of a process to map burrows, as in our Clermont foam study mentioned above. Although the time spent in the field with each activity was roughly comparable, mapping by excavation is an inefficient and crude technique compared to GPR. With GPR, we tested 14 sites in 8 field days, spending three to four hours at each site, including set-up time. Practically any burrow could be selected; with the excavation method only burrows listed on a State-issued permit could be imaged.

There are some limitations to the GPR method as well. Stott (1996) found that his GPR system exaggerated vertical tunnel height by a factor of 1.43. In our studies tunnel height could not be determined as the reflection derived from the top of the burrow in most cases was so high in amplitude that it effectively interfered with any reflections that might have occurred from the burrow base. In addition, the suitability of GPR to survey animal burrows in media other than dry sand can not be predicted. Although sand is well known as excellent for radar transmission, silty and clay-rich soils would likely attenuate energy prior to reaching the depth of burrows. For most intermediate-sized burrowing vertebrates that inhabit dry upland sandy regions of Florida, however, this would not be a problem. There have also been no tests of this technique with smaller (e.g., rodent) sized burrows. Burrows we surveyed were ca. 25–35 cm in width and 11–18 cm high. Our burrow camera showed the existence of smaller Florida Mice (*Podomys floridanus*) burrows intersecting the main tortoise tunnels, but our GPR profiles did not discern these smaller tunnels. It is possible that antennae with very high frequencies (greater than 900 MHz) could potentially be used to image smaller burrows, following techniques discussed in this paper. Higher frequency antennae have a greater resolution, but a shallower depth of total energy penetration. Finally, we were unable to confirm the presence of tortoises in two burrows where our camera showed that they were in fact there.

In our study, a catalog of the shape, depth, and orientation of burrows was produced for 14 Gopher Tortoise burrows in central Florida. Data were collected in dense grids of reflection profiles over 8 field days, which were then interpreted to show their orientation in three-dimensions. We demonstrated that the GPR method can be accurately and cost-effectively used in these types of studies for not only burrowing reptiles such as gopher tortoises, but potentially many other burrowing organisms. This imaging technique potentially has worldwide conservation implications for the study of these structures and the medium to large-sized vertebrates that dig and use them.

Ground-penetrating radar is one of the more complex near-surface geophysical methods and there is usually a learning curve involved for all who would like to use the technique. As with most tools, manuals are only partially helpful in standard set-up and data collection methods, which must usually be adjusted for each area studied. This is because ground conditions (soil type and

moisture) as well as the nature of the targets usually vary at different geographic sites. Some systems record directly to a laptop, but most record data internally within the radar control system for later downloading. Software to process received reflected data into profiles and three-dimensional images is available for each system, written by the manufacturer. A number of competing software packages are available, some for free on the internet, and some that necessitate yearly subscription expenses of about US $1500 or so. A complete GPR system costs about US $30,000 to purchase, but can be rented from a number of companies in the U.S. and around the world for about US $250 per day. If one wished to write a grant to use this technology in a study, perhaps US $2500 should be allocated for initial training, along with US $3000 for system rental for a few weeks. One should then plan on spending at least four weeks to learn the intricacies of this system in the field. The SlicerDicer program costs about US $600 (academic version US $450) and the FormZ program costs US $400. About one or two weeks is a reasonable time period required for one to effectively learn each program.

Acknowledgments.—We thank the Resource and Land Management staff of the Ocala National Forest, especially Ms. Janet Hinshee, for providing maps and data. Listing of name brand products does not convey endorsement by the University of Florida or the University of Denver.

Aquatic-breeding habitats are essential to many amphibian species that spend most of their life in terrestrial habitats. However, outside of the breeding season, it is difficult to find salamanders such as ambystomatids, hynobiids, and salamandrids. Post-breeding adults disperse upland, find refuge in subterranean burrows or under cover objects such as decaying logs, woody debris, leaves, and stones, and therefore cannot be readily found (Duellman and Trueb 1986). Because of their "unobservability" (sensu Verrell and Davis 2003) it is a common practice to survey for egg masses deposited in aquatic habitats as a means of detecting unknown sites of hynobiids (Hasumi and Kanda 1998). However, lack of roads or poor road conditions may hinder access to potential breeding sites, forestalling surveys. Darhadyn Wetland, Khovsgol Province, Mongolia (Fig. 1: 130 × 30 km area; 50°40'–51°40'N, 99°15'–99°45'E; 1540–1580 m elev.) seemed to correspond to such an inaccessible wetland.

The Siberian salamander *Salamandrella keyserlingii* (Hynobiidae) has the widest range of amphibians worldwide (Borkin 1999; Kuzmin 1999). This species is spread from eastern Europe to Kamchatka, and occurs sporadically in China, Japan, and Mongolia (Borkin and Kuzmin 1988). The Mongolian Red Data book has shown an anecdotal point of distribution for *S. keyserlingii* in Darhadyn Wetland (Shiirevdamba 1997). However, there was no mention of where this species existed within the large wetland. There also is a description of the occurrence of *S. keyserlingii* along the Shishkhid River, which flows through this wetland (Fig. 1, Site 5), but an accurate site location was not provided (Borkin and Kuzmin 1988). During and shortly after the breeding season (estimated to be early June), potential breeding sites of this species seemed to be inaccessible, except by horseback, due to poor road conditions caused by melting of the frozen soil.

If aquatic-breeding habitats cannot be accessed during spring at a target wetland, it may be helpful to conduct a summer survey of likely sites determined by inspection of a satellite picture (remote-sensing techniques: Carey et al. 2001). While larval surveys can be conducted during summer for many species and sites, at Darhadyn Wetland, larvae were rarely captured from crescent lakes and pools during summer because of their earlier metamorphosis (mostly during July: M. Hasumi, unpubl. data). Thus, trying to capture larvae during summer when roads become fully accessible (mid-July to August) is not a useful method to search for new sites of this species in Darhadyn Wetland. After metamor-

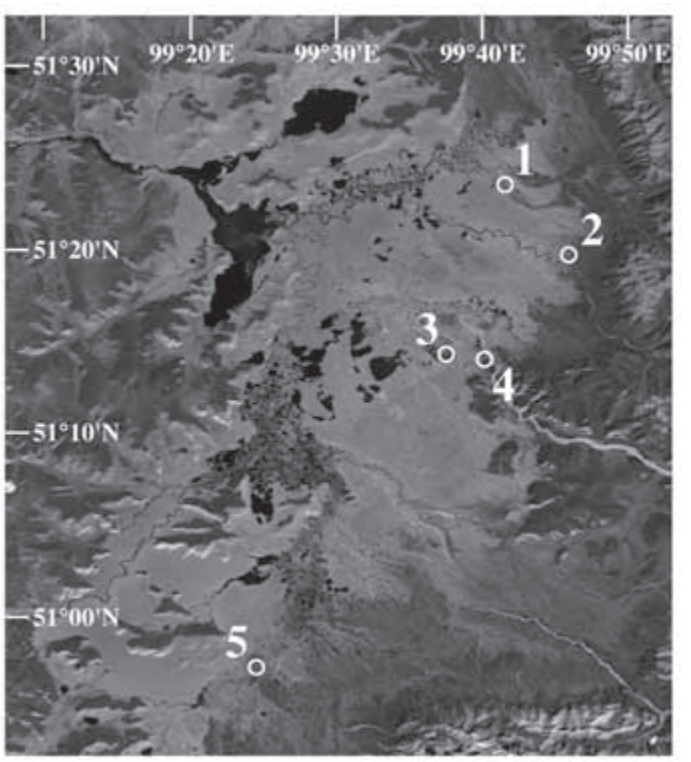

FIG. 1. A satellite picture of Darhadyn Wetland, Mongolia (excluding the northern and southern tips), photographed on 9 August 2001 from the Landsat (published by the ESDI), with five sites we examined for *Salamandrella keyserlingii* (open circles). A site was documented along the Khodon River (Site 2: 51°19'52"N, 99°45'52"E) and along the Shishkhid River (Site 5: 50°57'40"N, 99°24'30"E). No salamanders were found at three other sites proposed for salamander hunting (Site 1: 51°23'40"N, 99°41'30"E; Site 3: 51°14'20"N, 99°37'40"E; Site 4: 51°14'03"N, 99°40'10"E).

phosis, *S. keyserlingii* are nocturnal in summer (Grigoriev and Erdakov 1981); salamanders forage above ground at night and hide in cool, moist refugia during the daytime. Common refugia are decaying logs, and therefore searching forest zones adjacent to aquatic habitats may improve detectability of these salamanders. In this context, the aim of our study was to record occurrences of *S. keyserlingii* at potential sites with adjacent water bodies and forest zones, assessed by a satellite picture of the whole Darhadyn Wetland during the nonbreeding summer season, and to determine the efficiency of this method.

We utilized available Landsat pictures, which were published by the Earth Science Data Interface (ESDI) at the Global Land Cover Facility (University of Maryland, USA), and analyzed the most recent satellite picture of the whole Darhadyn Wetland, photographed on 9 August 2001. We chose Landsat pictures because of their availability and spatial scale including the entire wetland. Pictures from higher spatial resolution satellites such as IKONOS and SPOT were expensive, and while ASTER pictures were less expensive, they covered only one-third (western area) of this wetland by 2005. In band 4 of the Landsat data, having 760–900 nm wavelengths (infrared; 30 m resolution), water indicated a low value below 5% due to lack of its reflectance, but vegetation showed a high value around 40%. Thus, we could determine a site composed of both water bodies and forest zones with image processing. Where a river winds through the wetland, its track forms off-channel "oxbow" crescent lakes and pools (see Fig. 2A). In Darhadyn Wetland, the central region contained many areas like this, but these areas did not have much adjacent forest vegetation. Such areas with more forest vegetation were concentrated to the northeastern and eastern portions of the wetland. In this context, we proposed four potential habitats for salamander surveys (Fig. 1, sites 1–4).

We searched for *S. keyserlingii* at these four sites from 18–23 August 2005. At each site we conducted field reconnaissance and located bodies of water such as stream backwaters, crescent lakes, and pools by walking. We then went to the nearby forest zone and surveyed decaying logs for salamanders. We verified site locations and elevations using a Global Positioning System (GPS; eight satellites, to within 8 m), including the locations of logs. Distance between sites was calculated based on the satellite picture. We determined distance of a log that harbored any individual or the nearest water that was estimated to be suitable for oviposition, using a measuring tape and a GPS. We measured length and diameter of each log when it harbored individuals. We recorded "age class" (i.e., juvenile or adult), sex, and maturity of each individual, according to Hasumi (2001). We weighed each individual (body mass: BM, to within 0.05 g), and measured the broadest head width (HW), maximum tail height (TH), snout–anterior vent length (SAVL: distance from the tip of the snout to the anterior angle of the vent), snout–posterior vent length (SPVL: from the tip of the snout to the posterior angle of the vent), and tail length (TL: from the posterior angle of the vent to the tip of the tail) to within 0.01 mm by a modification of Wise and Buchanan's (1992) method without using anesthesia.

Additionally, at a suspected site along the Shishkhid River mentioned above (Fig. 1, Site 5; Fig. 2A), surveys were conducted from 18–23 July 2004 and from 6–17 August 2005. Previously, several individuals had been reported from this area (independent of analyzing a satellite picture) under decaying logs on land on 23 August 2002 (T. Hongorzul, unpubl. data) but related data were

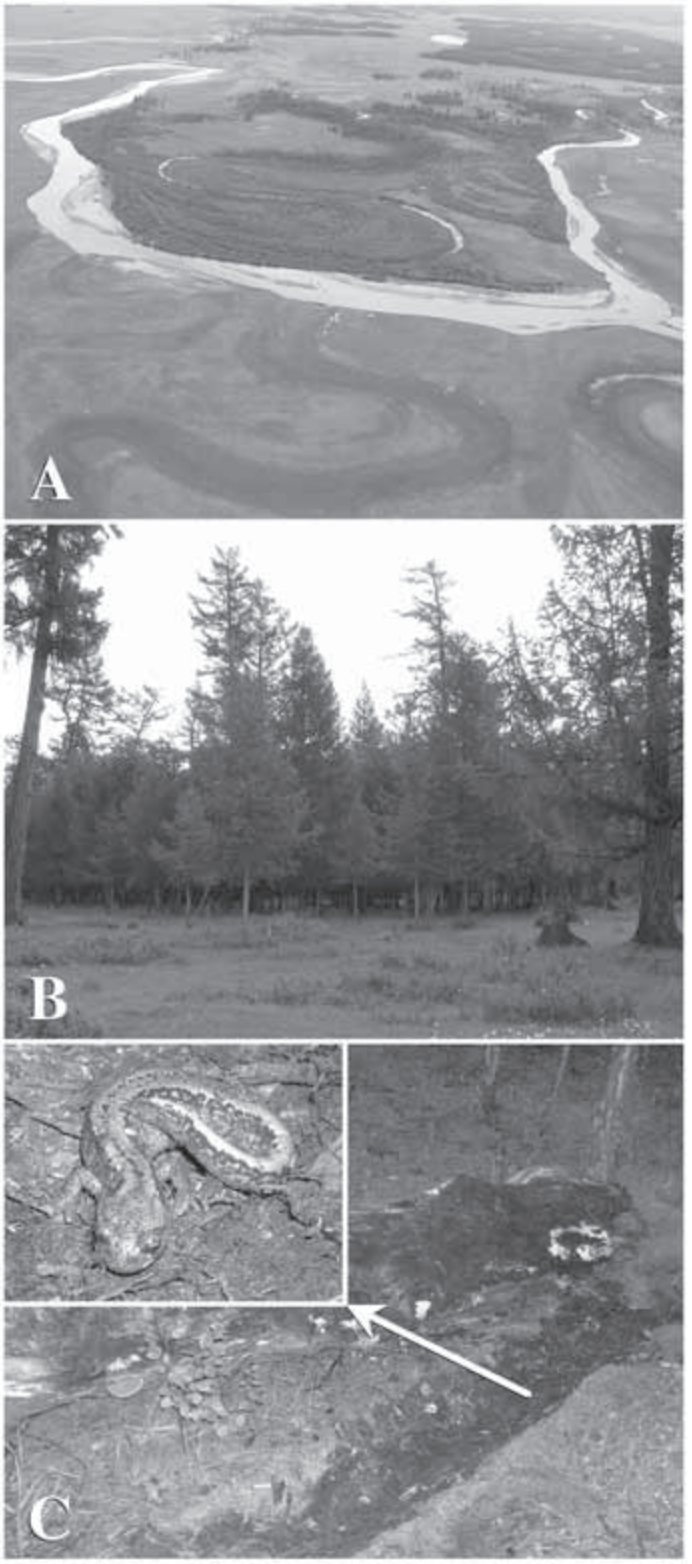

FIG. 2. Two sites of *S. keyserlingii* within Darhadyn Wetland, Mongolia: A) a bird's eye-view picture of site 5 (Fig. 1) with several off-channel crescent lakes and pools (photographed by T. Morita from a paraglider); B) a forest (*Larix* sp.) zone of site 2 (Fig. 1); and C) a decaying log under which a male was found.

not obtained at that time. This site is part of a separate mark–recapture study, and we report only occurrences here to better understand the distribution of the salamander at Darhadyn Wetland.

We detected salamanders at one of four sites selected from satellite imagery. This site occurred in a forest (*Larix* sp.) zone along the Khodon River at 1566 m elev. (Fig. 1, Site 2; Fig. 2B). In the forest, a male was discovered under a decaying log at 2010 h on 20 August 2005 (Fig. 2C). Due to near darkness at that time, this male was released after photographing, without measuring body size characteristics, and detailed site data were obtained from 1100–1320 h on the next day. The log was 3.0 × 0.4 m (length × diameter) and was 237 m from the nearest backwater (BW1). We found a stream approximately 400 m long with 20 or more backwater pools at the uppermost extent of BW1. Most of these backwaters appeared favorable for oviposition, but no larva was found. In this area, a second male (BM = 3.20 g, HW = 8.75 mm, TH = 4.85 mm, SAVL = 46.16 mm, SPVL = 49.53 mm, TL = 25.30 mm) was found under a decaying log (12.0 × 0.25 m) 5 m from the nearest backwater (BW2), located at a slope of the left bank (while looking downstream) near the water sources. There was 375 m distance between BW1 and BW2, and 439 m distance between the logs that harbored the first and second males.

We also found *S. keyserlingii* within a wetland complex in a floodplain along the Shishkhid River (40–60 m wide, 1560 m elev.; Fig. 1, Site 5; Fig. 2A). In summer surveys from 2004–2005, 299 individuals were collected by hand in and under decaying logs on land within the forest zone at this site. It is unknown whether or not this site corresponded to the site recorded previously (Borkin and Kuzmin 1988). In a follow-up survey in mid-May 2006, Site 5 (Fig. 1) could be accessed, but the water surface was frozen and no egg masses were found (M. Nakagawa, pers. comm.).

The distance between the first and second sites was 49.8 km. No salamander was found at three other sites proposed for salamander surveys (Fig. 1).

When aquatic-breeding habitats could not be accessed during spring, our summer surveys of water bodies and adjacent forest zones in the four sites proposed by a Landsat satellite picture were a relatively useful method, with a 25% detection rate of new *S. keyserlingii* sites. Although our approach was limited and we include only preliminary data, a satellite imagery method for predicting distribution of *S. keyserlingii* across huge and often inaccessible landscapes as found in Mongolia may have merits and broad applicability to other regions with similar landscapes. Our approach cannot definitely determine species absence. It is unknown whether or not a 50 km interval between the first and second sites (between the Khodon and Shishkhid Rivers) accurately reflects the distribution of *S. keyserlingii* in Darhadyn Wetland (Borkin and Kuzmin 1988). However, if this is the case, desertification or fragmentation of this wetland that now appears to be progressing due to climate changes melting the permafrost region (N. Fuji, unpubl. data), is a potential explanation for the species occurring at potentially isolated sites. Analyses of satellite images through time are needed to assess changes in wetland–forest habitat conditions, which also could be modeled into the future. While this is a broad-ranging species, its loss at specific sites across its range may be a concern for local population stability.

Acknowledgments.—We are greatly indebted to Takashi Morita for kindly providing a bird's eye-view picture, Norio Fuji for permitting us to use his unpublished data, and Masahiro Nakagawa for giving us information on road conditions and egg mass deposition. We express our gratitude for the constructive comments of Dede Olson, Leo Borkin, Klaus Richter, and Olaf Niemann. This study was financially supported in part by Grants-in-Aid for Scientific Research from the Japan Fund for Global Environment (Environmental Restoration and Conservation Agency of Japan) and the Aeon Environment Foundation (Japan).

Digital Recorders Increase Detection of *Eleutherodactylus* Frogs

LUIS J. VILLANUEVA-RIVERA
Department of Biology, University of Puerto Rico
Box 23360, San Juan PR 00931-3360

Improved methods for large-scale and long-term amphibian monitoring projects would aid species status assessments and identification of potentially declining species (e.g., Stuart et al. 2004). Acoustical surveys allow researchers to quickly determine species presence and calling activity level (Lips et al. 2001; Zimmerman 1994). The North American Amphibian Monitoring Program, a large-scale monitoring effort, uses acoustical surveys to monitor species in ponds and wetlands (United States Geological Survey 2004). A challenge of this approach is accurate species identification, which is particularly problematic in a tropical area with high anuran species diversity (e.g., anuran species richness in the Neotropics [2135] was greater than in the Neartic [90], Duellman 1999). Furthermore, abundant or loud species may lower the detection probability of other species.

An assumption that needs to be tested in acoustical surveys is that detection is highly correlated with the species presence or activity. Without an appropiate correction for detection probability, data will not accurately reflect the status of the species (MacKenzie et al. 2002). This may result in inappropriate management decisions that could waste time and money.

Digital recorders can be used as a standard method for species detection and determination of calling activity level in amphibian choruses in long-term monitoring projects. Digital recordings can be stored and transferred easily and can allow experts to analyze the recordings at their convenience. In addition, loud or abundant species can be filtered using computer software to increase the detection of other species. I tested the hypothesis that detection of species presence and calling activity level in anuran choruses will be higher when recordings are analyzed with the help of computer software compared to only hearing the recordings. The resulting increase in detection should result in improved population status data and reduced false negatives during species inventories (i.e., when a species is not detected due to interference).

Materials and Methods.—I recorded amphibian choruses at two sites in the Luquillo Experimental Forest (Tradewinds Trail site, 18.290°N, 65.798°W; Mount Britton Tower site, 18.303°N, 65.795° W), and at one site in the Carite State Forest (18.103° N, 66.035° W), Puerto Rico (Fig. 1). The Tradewinds and Mount Britton sites were located in the Lower Montane Wet Forest lifezone and the Carite State Forest site was located in the Subtropical Wet Forest lifezone (Ewell and Whitmore 1973). Recordings were made using an Automated Digital Recording System (ADRS; Acevedo and Villanueva-Rivera 2006). The recorder was a Nomad Jukebox 3 digital player and recorder (Model DAP-HD0003, Creative Labs, Inc, California), and was set to record in 16-bit wav files with a sampling rate of 48 kHz. Because the recorder had no microphone input, only a line level input, the microphone was connected to a portable preamplifier (Model SP-PREAMP, The Sound Professionals, Inc., New Jersey).

To test if digital recordings can be used to increase detection in tropical frog choruses, I compared one minute recordings, made at 2000, 2200, and 0000 h on five consecutive days, for a total of fifteen recordings per site. I analyzed these recordings using two methods: 1) listening to the recordings; and 2) listening and analyzing the recordings using computer software. For the first method I listened to the recordings with headphones, and each species heard was given an Amphibian Calling Index value (ACI; United States Geological Survey 2004). The ACI has four possible values: 0—no animals calling; 1—a few animals calling without overlap; 2—some overlap of animals calling; and 3—a full chorus of the species. For the second method, I listened to the recordings with headphones and analyzed them using computer software to detect the signal of each species' call by their sound and visual pattern in the auditory spectrum. There is little overlap in the call spectrum of the *Eleutherodactylus* frogs in Puerto Rico, and thus it was possible to distinguish each species (Drewry and Rand 1983). In addition, recordings of the calls of all the species have been published (Rivero 1998). Each recording was then filtered to remove the range of frequencies of the dominant species, *Eleutherodactylus coqui* (1–2.4 kHz), and re-analyzed. I gave each species a new ACI value for this second method. All recordings were coded and analyzed in random order to reduce bias. Each pair of results, for each recording, by species, were compared using Wilcoxon signed ranks tests.

To evaluate the differences in the level of the recorded sound of the species, which may explain why some species were not heard, I obtained the average signal level by frequency using the values of decibels full scale (dBFS), which corresponds, on a logarithmic scale, to the signal in the digital file. On this scale the maximum is 0 dB and the minimum is -96 dB, which corresponds to the maximum and minimum levels, respectively, of sound that the

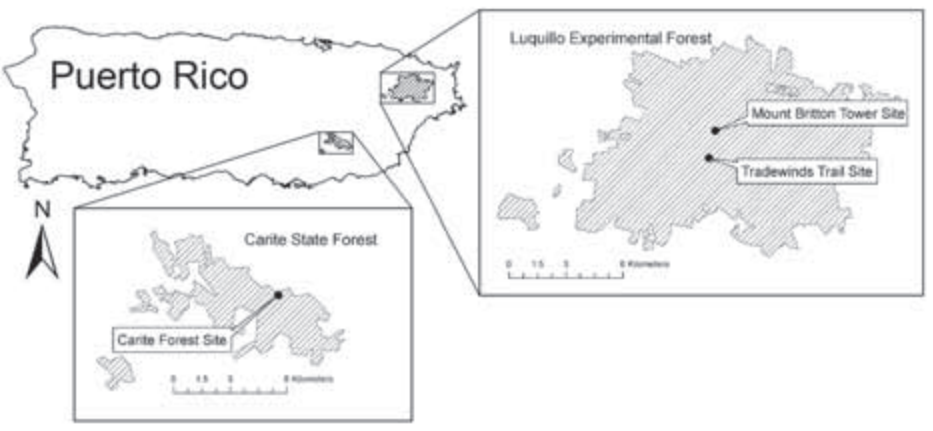

FIG. 1. Location of the three study sites in Puerto Rico.

digital file can store (Fries and Fries 2005). The recordings were analyzed using the program AUDITION (ver. 1.0, Adobe Systems, Inc., California, USA).

Results.—A total of eight species of *Eleutherodactylus* frogs were detected. Seven species were detected at the Tradewinds Trail site (Fig. 2a), where there was no difference between the methods

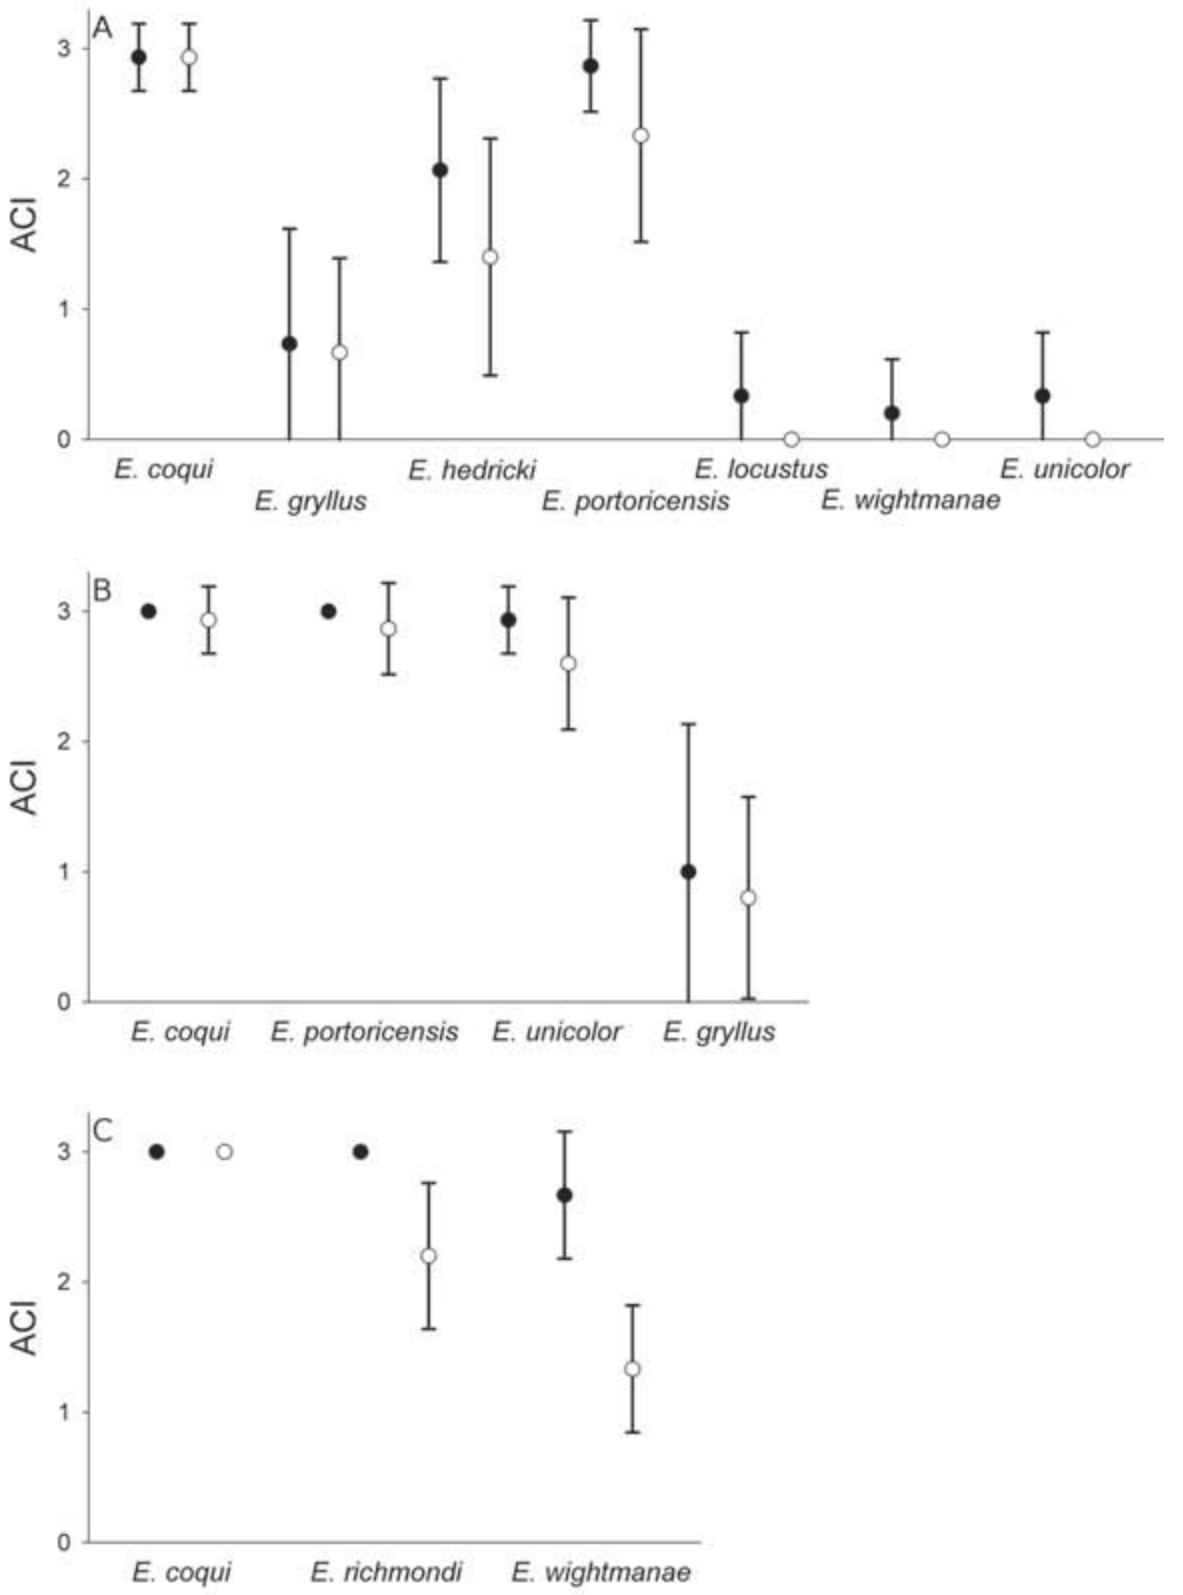

FIG. 2. ACI values (mean ± SD) per species using two methods at: A) Tradewinds Trail site; B) Mount Britton Tower site; and C) Carite Forest site. Filled circles = values for computer analysis method. Open circles = values for the listening method.

for *E. coqui* and *E. gryllus*. The ACI values of two species were higher on the computer-analyzed recordings: *E. hedricki* (P = 0.016) and *E. portoricensis* (P = 0.022). Three species were detected only when the signals of their calls were seen in the spectrogram and the recordings were filtered: *E. locustus*, *E. unicolor,* and *E. wightmanae*. I detected *E. locustus* and *E. unicolor* in five of the

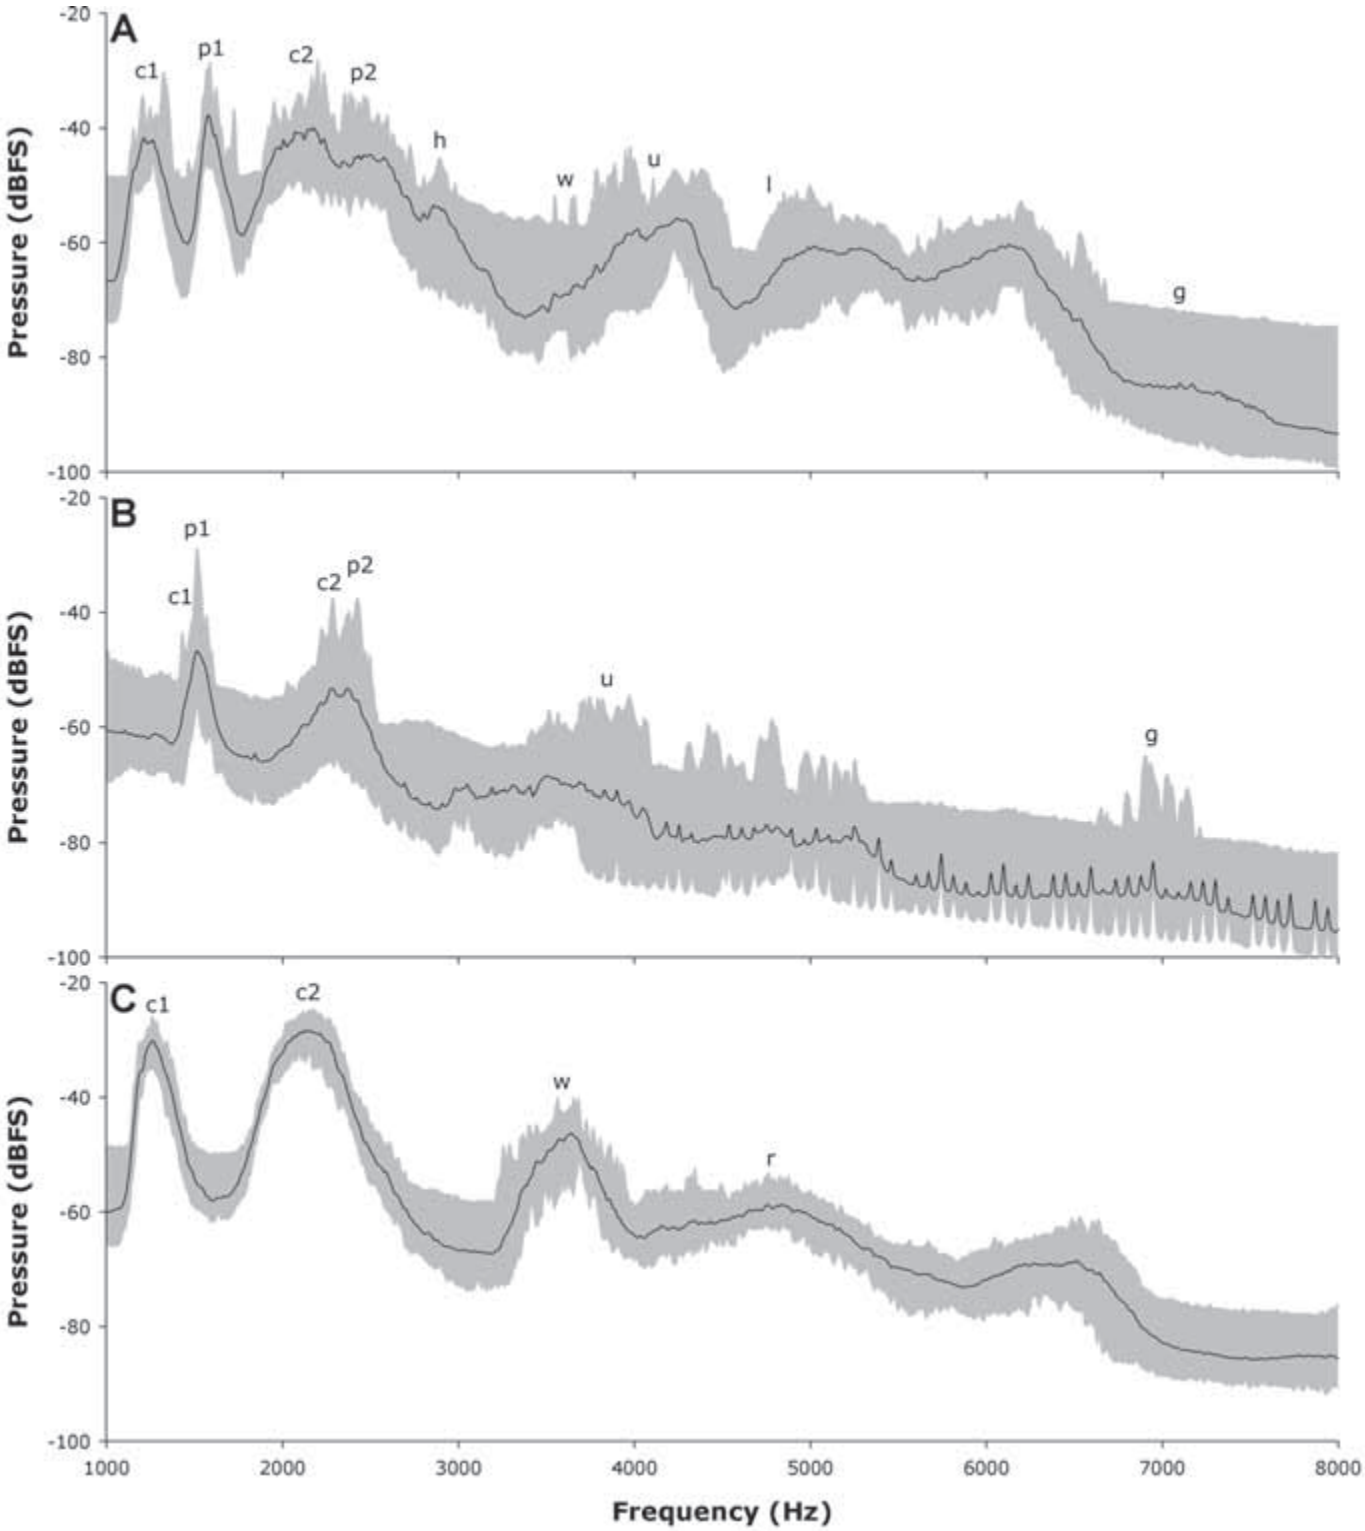

FIG. 3. Sound pressure by frequency of species of *Eleutherodactylus* frogs at the (A) Tradewinds Trail site, (B) Mount Britton Tower site, and (C) Carite Forest site. Sound pressure is measured in decibels full scale (dBFS). The black line represents the average for the fifteen recordings at each site and the shaded area encloses the range of values for each frequency. Letters above the graphs represent the dominant frequency for the species. c1 = first note of *E. coqui*; c2 = second note of *E. coqui*; p1 = first note of *E. portoricensis*; p2 = second note of *E. portoricensis*; h = *E. hedricki*; w = *E. wightmanae*; u = *E. unicolor*; l = *E. locustus*; r = *E. richmondi*; g = *E. gryllus*. Other peaks represent sounds made by insects.

fifteen recordings and *E. wightmanae* in only three of fifteen recordings. Two species had the highest sound pressures, *E. coqui* and *E. portoricensis* (Fig. 3a). The average level of the signal was -41.7 dB and -40.0 dB for the first and second notes of *E. coqui*, respectively, and -37.7 dB and -44.7 dB for the first and second notes, respectively, of *E. portoricensis*. The average maximum signal level for *E. locustus* was -50.7 dB, 13.0 dB less than the average of the loudest species, *E. portoricensis*. The average maximum signal level of *E. unicolor* was -44.5 dB and for *E. wightmanae* was -43.3 dB; these values were 6.8 dB and 5.6 dB lower than the loudest species, respectively.

There were four species at the Mount Britton Tower site: *E. coqui*, *E. gryllus*, *E. portoricensis*, and *E. unicolor*. There was no significant difference between methods for the four species (Fig. 2b).

I detected three species at the Carite State Forest site (Fig. 2c). There was no difference between methods for *E. coqui*, but the other two species had higher ACI values when analyzed by computer: *E. richmondi* (P = 0.004) and *E. wightmanae* (P = 0.002). The highest signal level was made by *E. coqui*, with -30.1 dB and -28.4 dB for the first and second notes, respectively (Fig. 3c). The average signal level for *E. richmondi* was -58.8 dB, 30.4 dB less than *E. coqui*, and for *E. wightmanae* it was -46.3 dB, 17.9 dB less than the loudest species.

Discussion.—The loudest species at the study sites, *E. coqui* and *E. portoricensis*, had a continuous chorus. In addition, the sound pressure of these species was higher than the species that were not as easily detected, up to 30 dB louder (Fig. 3). The continuous loud chorus of *E. coqui* and *E. portoricensis* caused interference in the detection of the other species.

The detection and level of activity measured using the ACI increased at two of three sites when recordings were filtered and the spectrogram was evaluated in the computer compared to only listening to the recordings. Of particular importance was the detection of three species, *E. locustus*, *E. unicolor*, and *E. wightmanae* at one of the sites only after filtering. These three species appear to be threatened or endangered since their range is restricted and few populations are known (Burrowes et al. 2004; pers. obs.).

Digital recordings, and their analysis using software, can be used as a tool to search for populations with apparently limited distributions, in areas where limited herpetological work has been conducted, and where loud species interfere with the detection of others. The ACI of four species was higher when the recordings were filtered to remove the common and loud *E. coqui*. Two of these four species, *E. hedricki* and *E. portoricensis*, have limited distribution in the highlands of Puerto Rico, and the two other species, *E. richmondi* and *E. wightmanae*, are thought to have only a few small populations (Burrowes et al. 2004; Villanueva-Rivera 2006).

Furthermore, recordings and computer analysis of choruses may advance our knowledge of anuran breeding phenology. For example, Bridges and Dorcas (2000) found that *Rana sphenocephala*, a species that was thought to be breeding only during the spring and fall, was also calling during the summer between 0200 and 0500 h. This finding, made with a cassette-based automated recording system, indicated a calling period that was missed by most herpetological work done in the area (Bridges and Dorcas 2000).

The use of digital recordings has important implications for the current discussion of amphibian declines and the need for long-term monitoring projects. In a study that tested the use of recorders to detect species of birds, several experts agreed on the identifications of the species present in the recordings, so the method was recommended as an effective avian monitoring method (Rempel et al. 2005). In another study, the number of species identified with recordings made with an ADRS was higher when compared to point counts for birds and transects for amphibians (Acevedo and Villanueva-Rivera 2006). For amphibian monitoring projects, technicians can deploy ADRS and record choruses to be analyzed by experts in the laboratory at another time. This can reduce personnel costs, especially for areas with a small temporal window of amphibian reproductive activity, areas that have high frog diversity, species that do not congregate, and species with low detection probabilities. Another important advantage is that a recording is a permanent record of the presence of a species. Lastly, as demonstrated here, digital recorders and use of computer software may help detect rare species or calls that are difficult to detect due to interference.

Acknowledgments.—I thank my thesis committee, J. Thomlinson, T. M. Aide, A. Sabat, and R. Thomas, for their help and suggestions. For analysis suggestions I thank C. Restrepo, C. Monmany, and H. Perotto. This research was conducted under the authorization of the Department of Natural and Environmental Resources of Puerto Rico (permit 02-IC-068) and the United States Forest Service (permit CNF-2038). Part of this research was funded by a fellowship from the "Attaining Research Extensive University Status in Puerto Rico: Building a Competitive Infrastructure" award from the National Science Foundation (0223152) to the Experimental Program to Stimulate Competitive Research at the University of Puerto Rico, Río Piedras Campus. I also thank the Department of Biology, the Deanship of Graduate Studies and Research, and the CREST-Center for Applied Tropical Ecology and Conservation of the University of Puerto Rico, Río Piedras Campus, for their support.

A Comparison of the Effectiveness of Recommended Doses of MS-222 (tricaine methanesulfonate) and Orajel® (benzocaine) for Amphibian Anesthesia

KRISTEN K. CECALA
STEVEN J. PRICE
and
MICHAEL E. DORCAS
Department of Biology, Davidson College
Davidson, North Carolina 28035-7118, USA

e-mail (KKC): krcecala@davidson.edu
(SJP): sjprice@davidson.edu
(MED): midorcas@davidson.edu

Traditionally, tricaine methanesulfonate (Ethyl 3-aminobenzoic methanesulfonate salt), commonly known as MS-222, has been used to anesthetize amphibians for a variety of procedures including surgery, marking, and photography (Anholt et al. 1998; Kaplan 1969; Kaiser and Green 2001). Recently, Orajel®, a widely used analgesic for oral pain in humans, has been suggested as an effective alternative (Brown et al. 2004; Chen and Combs 1999). Previous studies also have suggested that Orajel® may be a more convenient choice (Altig 1980; Chen and Combs 1999) because it may be purchased from pharmacies and convenience stores, is relatively inexpensive (Crook and Whiteman 2006) and may be easier to transport (Kaiser and Green 2001; Wright 2001).

Few studies have examined the responses of amphibians to either MS-222 (Anholt et al. 1998; Kaplan 1969; Lowe 2004) or Orajel® (Brown et al. 2004). Crook and Whitman (2006) found that benzocaine, the active ingredient in Orajel®, was more effective than MS-222 for anesthetizing *Ambystoma tigrinum*, and Cakir and Strauch (2005) found that benzocaine had more associated health risks than MS-222 in *Rana pipiens*. No other studies have compared the effectiveness of MS-222 and Orajel® among amphibian groups with dissimilar physiology that may affect their responses to anesthesia (Fellers et al. 1994). For example, factors such as rate of gas exchange across the skin vary among groups (e.g., plethodontid and ambystomatid salamanders), and may alter rates of anesthesia uptake.

We examined the effectiveness of recommended doses of MS-222 and Orajel® on four North American amphibian species (Northern Cricket Frogs [*Acris crepitans*], Mole Salamanders [*Ambystoma talpoideum*], Fowler's Toads [*Bufo fowleri*], and Northern Dusky Salamanders [*Desmognathus fuscus*]) by measuring the length of time required until induction, initial recovery, complete recovery, and the entire anesthesia process.

Methods.—We collected 54 adult *A. crepitans*, 41 adult *B. fowleri* and 46 adult *D. fuscus* from various localities within the western Piedmont of North Carolina, USA, and 16 adult *A. talpoideum* were collected on the Savannah River Site in the upper Coastal Plain of Aiken and Barnwell counties, South Carolina, USA. The snout-vent lengths ranged: 18–27 mm for *A. crepitans*; 29–64 mm for *B. fowleri*; 28–78 mm for *D. fuscus*; and 47–61 mm for *A. talpoideum*. After capture, we minimized stress by housing animals in dark containers with paper towels wetted with aged tap water. We housed *A. crepitans* and *D. fuscus* in same-species pairs in 18 × 18 × 7 cm plastic containers and housed *A. talpoideum* and *B. fowleri* in species-specific 75 × 32 × 30 cm aquariums with no more than 20 individuals per aquarium. *Acris crepitans*, *B. fowleri*, and *A. talpoideum* were kept at room temperature (ca. 21°C), and *D. fuscus* individuals were kept at 4°C but allowed to equilibrate to room temperature 3 h prior to testing. Individuals were kept no longer than a week prior to testing and monitored for at least 24 h before release. We prepared anesthesia solution by adding the recommended doses, 0.50 g/L for MS-222 (0.05%, Fellers et al. 1994) and 1.0 g/L of maximum strength Orajel® (Active ingredient: 20% benzocaine, Brown et al. 2004), to 1 L of 20–22°C, de-chlorinated tap water prepared by allowing chlorine evaporation overnight. We chose not to use a pH buffer with MS-222 as recommended by Lowe (2004) because we did not detect substantial pH change during use, as measured initially by a pH meter (YSI pH100; MS-222 pH = 6.53 ± 0.14, N = 6, Orajel® pH = 7.13 ± 0.08, N = 6) and by hydrion test strips (Micro Essential Laboratory, Inc.) following the last use of a solution (MS-222 pH = 7, N = 6, Orajel® pH = 7, N = 6). Baths were prepared in containers that allowed *D. fuscus* and *A. talpoideum* to completely submerge within the anesthesia solution. *Acris crepitans* and *B. fowleri* were placed in containers that allowed them to maintain their head above the solution until anesthetized.

After we prepared the solutions, individuals were arbitrarily assigned to two groups, either MS-222 or Orajel®, and no more than three individuals at a time were placed in their respective anesthesia solutions (Peterman and Semlitsch 2006). Animals were removed from the anesthetic solution when they failed to respond to our stimulus. We used a toe pinch as our stimulus and administered the pinch every minute in the anesthesia bath and every 2 minutes after induction until complete recovery. All amphibian species groups were tested separately, replacing anesthesia solutions after 15 animals were tested or after 1.5 h of testing. We defined "time until induction" as the period of time necessary for an individual to fail to respond to the toe pinch after being placed in the anesthesia bath. When the animal no longer responded to

our stimulus, we removed animals from the anesthesia bath and rinsed them for 30 seconds in a de-chlorinated water bath. We then placed test animals on moist paper towels, observed, and recorded time until the first response to a toe pinch, which defined our "time until initial recovery." At this point, we visually monitored individuals until they exhibited behavior with no signs of sluggishness or disorientation associated with anesthesia. We defined this time period to be the "time until complete recovery." We chose to use a toe pinch as our stimulus as opposed to a typical righting response (Crook and Whiteman 2006) because our use of anesthesia occurs mainly during injections of visual implant elastomer (Northwest Marine Technology; e.g., Nauwelaerts et al. 2000), and animals frequently responded to elastomer injections (i.e., were not completely anesthetized) even when they failed to right themselves.

We analyzed our data using a MANCOVA (Minitab ver. 12.1) for each species. We used anesthesia type as the independent variable, mass of individual as a covariate, and time until induction, time until initial recovery, time until complete recovery, and the total time for all three stages of anesthesia as dependent variables. We evaluated significance at an $\alpha = 0.05$ level in all statistical tests. Because of the unexpected mortality of *B. fowleri*, we used logistic regression (Hosmer and Lemeshow 1989) to examine the effects of mass, snout–vent length, and treatment on mortality. We used a stepwise procedure with an inclusion/removal cutoff of p = 0.10. This analysis was conducted using the SAS statistical package (SAS v. 9.1, SAS Institute, Cary, North Carolina, USA).

Results.—We found that Orajel® required less time until induction in all species tested (MANCOVA: *A. crepitans*, F = 46.38, df = 1, 51, p < 0.001; *A. talpoideum*, F = 24.21, df = 1, 13, p < 0.001; *B. fowleri*, F = 36.96, df = 1, 36, p < 0.001; *D. fuscus*, F = 20.99, df = 1, 42, p < 0.001; Fig.1), produced longer times until initial recovery in *A. crepitans, B. fowleri*, and *D. fuscus* (MANCOVA: *A. crepitans*, F = 148.73, df = 1, 51, p < 0.001; *B. fowleri*, F = 21.39, df = 1, 36, p < 0.001; *D. fuscus*, F = 70.77, df = 1, 42, p < 0.001; Fig. 1a–c), but a shorter initial recovery period in *A. talpoideum* (MANCOVA: F = 10.65, df = 1, 13, p = 0.006; Fig. 1d). Anesthesia type had no effect on complete recovery times in *A. crepitans, A. talpoideum,* or *D. fuscus* (MANCOVA: *A. crepitans*, F = 0.16, df = 1, 51, p = 0.69; *A. talpoideum*, F = 2.27, df = 1, 13, p = 0.156; *D. fuscus*, F = 0.24, df = 1, 42, p = 0.626; Fig. 1 a, b, d), but anesthetization using Orajel® resulted in a longer period until complete recovery in *B. fowleri* (MANCOVA: F = 14.55, df = 1, 36, p < 0.001; Fig. 1c). Anesthesia using Orajel® took less time for the entire anesthesia process in *A. crepitans* and *A. talpoideum* (MANCOVA: *A. crepitans*, F = 23.71, df = 1, 51, p < 0.001; *A. talpoideum*, F = 28.46, df = 1, 13, p < 0.001; Fig. 2), but more time in *B. fowleri* and *D. fuscus* (MANCOVA: *B. fowleri*, F = 24.74, df = 1, 36, p < 0.001; *D. fuscus*, F = 17.71, dF = 1, 42, p < 0.001; Fig. 2). Mass significantly affected time until induction in

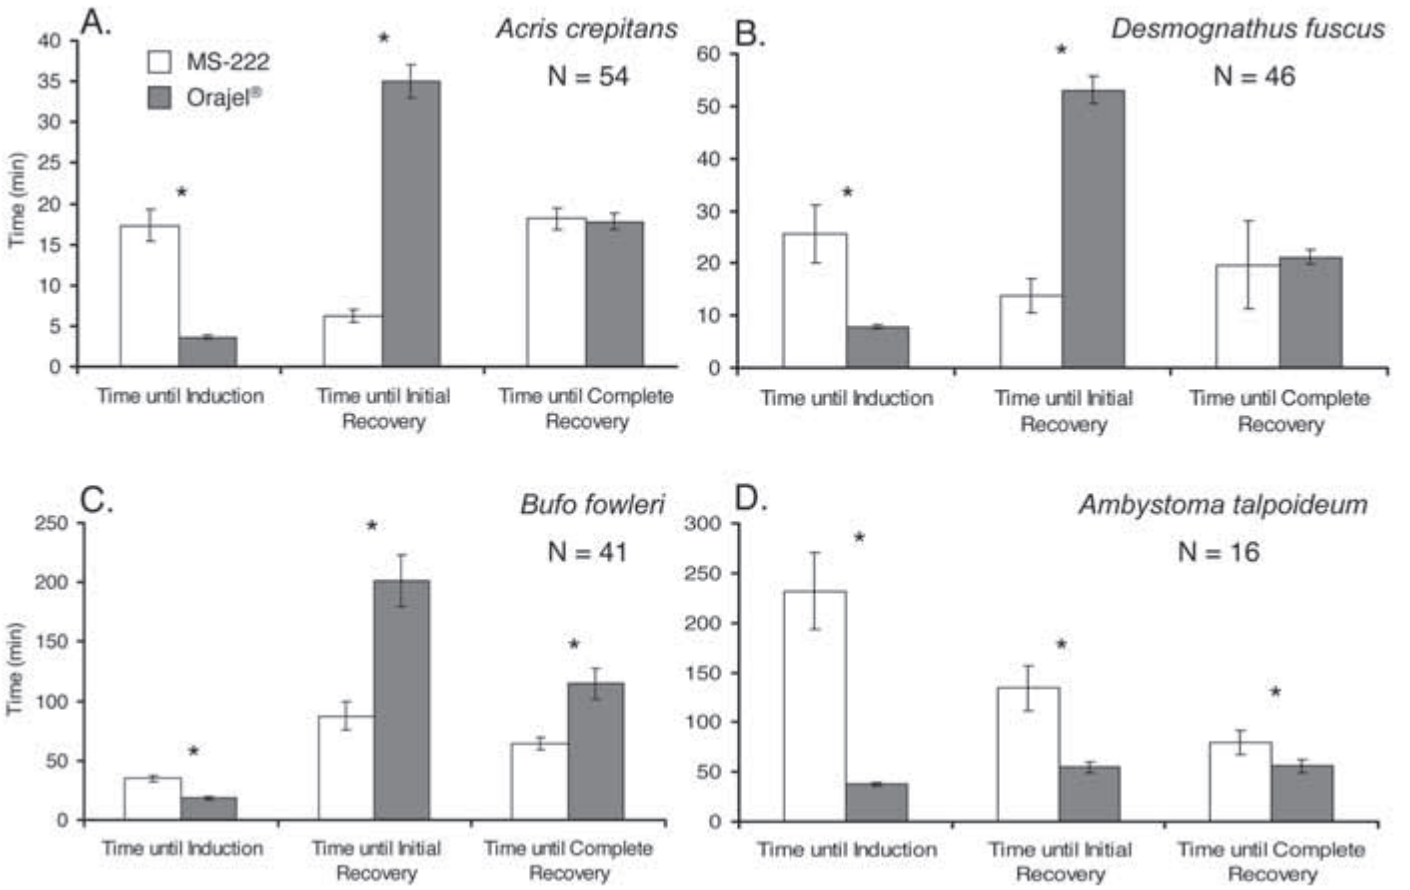

FIG. 1. Time (mean ± SE) required for the three stages of anesthesia using MS-222 and Orajel® in each test species. "*" indicates p < 0.001 (MANCOVA).

B. fowleri and *D. fuscus* (MANCOVA: *B. fowleri*, $F = 16.91$, $df = 1, 36$, $p < 0.001$; *D. fuscus*, $F = 8.53$, $df = 1, 42$, $p = 0.006$). We recorded relatively high mortality rates for *B. fowleri* in Orajel® (35%) and MS-222 (12%), but no mortality occurred in the other species tested. Results of our stepwise logistic regression identified mass as the best predictor of mortality, with heavier individuals having a higher probability of death (model likelihood ratio statistic = 4.9528, $p = 0.026$; parameter estimate for mass = -0.1193, $p = 0.032$).

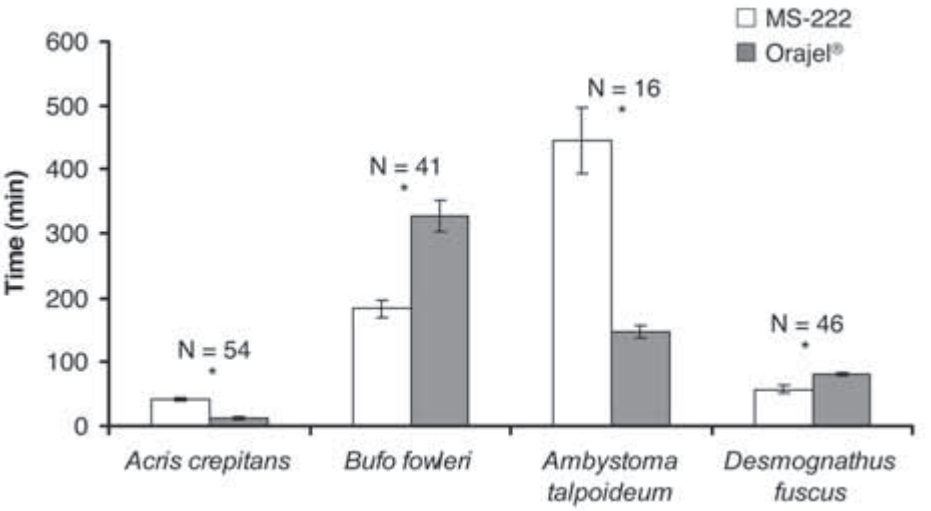

FIG. 2. Time (mean ± SE) required for the entire anesthesia process using MS-222 and Orajel® on our 4 test species. "*" indicates $p < 0.001$ (MANCOVA).

Discussion.—We observed that for most of the amphibian species we tested, anesthetization using Orajel® required less time for induction and produced a longer anesthetization period with variable recovery periods than recommended doses of MS-222 (Fig.1). The effect of anesthesia type on the time required for the entire anesthesia process varied among species (Fig. 2). We attribute inconsistent effects of anesthesia to variation in the physiologies of the species we tested. Factors such as methods of gas exchange, differing metabolic rates, or variation in water absorption rates likely impacted the reactions of species to each anesthesia (Feder and Burggren 1992).

Differences in time required for the three periods of the anesthetization process for each species also may have been a function of mass. We detected a positive effect of mass on induction time in *B. fowleri* and *D. fuscus*. Our sample contained individuals with masses ranging from 2.1 to 27.3 g in *B. fowleri* and 0.5 to 6.5 g in *D. fuscus*. Conversely, we were unable to detect any effect of mass in *A. crepitans* and *A. talpoideum*, which might be a result of testing similarly sized individuals (masses ranged from 0.4 to 1.6 g in *A. crepitans* and 3.9 to 7.6 g in *A. talpoideum*). Contrary to Lowe (2004) but similar to Peterman and Semlitsch (2006), we found that heavier individuals of some species required more time for induction than individuals that weighed less.

An unexpected result of our study was mortality experienced by *B. fowleri*. Orajel® and MS-222 have been used for euthanasia, but typically concentrations are higher or applied differently (Altig 1980). The mortality we observed might be attributed to behavioral and physiological responses of toads to physical handling. During handling, toads frequently released water from their cloacas. Toads might have rapidly absorbed water through their "pelvic patch" (Brekke et al. 1991) in response to water loss. Thus, they might have absorbed more anesthesia than necessary for anesthetization, effectively acquiring a lethal dose before showing signs of reduced motor coordination. Results from our logistic regression suggest that these effects may be most pronounced in heavier individuals. Despite the mortality we witnessed in toads, we suspect that Orajel® and MS-222 are safe for many non-bufonid species. For example, although not included in this study, we also have anesthetized several other species of larval and adult amphibians, including *Ambystoma maculatum*, *Eurycea cirrigera*, and *Pseudotriton ruber*, safely in Orajel® and have experienced no mortality. Yet, our study and others suggest the importance of experimenting with anesthesia type prior to anesthetizing many individuals because effects may vary between different species and life stages (Crook and Whiteman 2006).

Researchers should consider several factors when choosing an anesthesia. For example, researchers needing to work quickly in a field setting may want to consider the anesthesia that requires the least amount of time for the entire anesthesia process. Conversely, if total time or recovery time is less of a concern, researchers may choose to use the anesthesia that produces the shortest induction period, which was Orajel® in all tested species. Investigators choosing anesthesia may also consider the procedures they are conducting such as visual implant elastomer injections or implantation of radio transmitters, because a long anesthetization period may be required. For these longer procedures, Orajel® appears to be a better option for many species (Fig. 1).

Various other factors also may affect a researcher's choice of anesthesia. Although MS-222 must be purchased from a chemical supply company (Brown et al. 2004), Orajel® is a common oral analgesic, can be found at most convenience stores, and is slightly less expensive per dose than MS-222 (Orajel®: CVS Pharmacy in Davidson, NC, US $0.65/dose; MS-222: Sigma Aldrich US $0.87/dose). We also observed that, similar to Crook and Whiteman (2006), Orajel® anesthesia baths anesthetized more individuals than MS-222 baths. Furthermore, although there are no known negative side effects of low doses of Orajel® on amphibians, MS-222 may decrease natural cutaneous gram-negative bacterial growth (Fedewa and Lindell 2005).

Based on our study, researchers should prioritize their needs while choosing anesthesia for amphibians. Orajel® appears to be a relatively safe, quick, and convenient anesthesia, but MS-222 may be a better choice when the study organism requires less time for the entire anesthesia process, or the study organism's mortality risk due to anesthesia is high and/or the study species is of special conservation concern.

Acknowledgments.—We thank W. Anderson, N. DiLuzio, L.A. Harden, T. Luhring, T. Mills, C. Westfall, and J.D. Willson for assistance with animal collection. We also thank L.A. Harden, B. Todd, and C. Westfall

for providing comments that improved the manuscript and H. Whiteman for advice that improved the study. Some animals for this study were collected at Mecklenburg County's Cowan's Ford Wildlife Refuge. All procedures were approved by the Davidson College Animal Care and Use Committee, (3-05-17; 2006). Manuscript preparation was aided by the Environmental Remediation Sciences Division of the Office of Biological and Environmental Research, U.S. Department of Energy through Financial Assistance Award number DE-FC09-96SR18546 to the University of Georgia Research Foundation. Funding was provided by: Davidson College Department of Biology; a Grant-in-Aid-of-Research from the National Academy of Sciences, administered by Sigma Xi, The Scientific Research Society; a Yarbrough Research Grant administered by the Collegiate Academy, North Carolina Academy of Science; Duke Power; and National Science Foundation grants (DEB-0347326 and DBI-1039153) to MED.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations in the field, with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance.

Electronic submission of manuscripts is requested (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments). Authors without the ability to send manuscripts electronically may supply hard copy instead. Figures can be submitted electronically as JPG files, although higher resolution TIFF or PDF files will be requested for publication. Please DO NOT send graphic files as imbedded figures within a text file. Additional information concerning preparation and submission of graphics files is available on the SSAR web site at: http://www.ssarherps.org/HRinfo.html. Manuscripts should be sent to the appropriate section editor: **Marc P. Hayes** (amphisbaenids, crocodilians, lizards, and *Sphenodon*; mhayesrana@aol.com); **Charles W. Painter** (amphibians; charles.painter@state.nm.us); **Andrew T. Holycross** (snakes; holycross@asu.edu); and **James Harding** (turtles; hardingj@pilot.msu.edu).

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother [2000. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, with Comments Regarding Confidence in Our Understanding*. Herpetol. Circ. 29:1–82; available online at <http://herplit.com/SSAR/circulars/HC29/Crother.html>]; for Mexico as it appears in Liner [1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herpetol. Circ. 23:1–113]), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhyacosiredon leorae*. Size. Herpetol. Rev. 25:22.

CAUDATA

AMBYSTOMA TALPOIDEUM (Mole Salamander). **PREDATION**. On 15 May 2005, I observed a Nine-banded Armadillo (*Dasypus novemcinctus*) foraging along a drift fence at Ellenton Bay, a Carolina bay on the Savannah River Site in Aiken County, South Carolina, USA. It was a wet night with light rain falling, and many metamorphic Mole Salamanders were moving from the wetland toward surrounding terrestrial habitat. They were slowed and concentrated spatially by the drift fence of buried aluminum flashing, increasing their vulnerability to predators. The armadillo moved slowly along the fence, devouring salamanders repeatedly. On several occasions, it did not take the tail and I verified that the prey were Mole Salamanders by collecting these tails. Although I observed many salamanders captured in bucket traps along the fence during the night, they had all disappeared by morning; only parts of carcasses remained strewed around the traps. Because escape from these buckets was highly unlikely, armadillos probably ate most of these salamanders. Later in the migration season, I observed several individual armadillos foraging simultaneously at the same site. These observations indicate that nine-banded armadillos can be formidable predators of ambystomatid salamanders, perhaps severely affecting their populations when indirectly offered easy foraging opportunities by standard sampling

techniques for amphibians.

To my knowledge, this is the first report of Nine-banded Armadillos preying on Mole Salamanders. Several studies have reported that armadillos feed on various salamander species (Breece and Dusi 1985. *In* Montgomery [ed.], The Evolution and Ecology of Armadillos, Sloths, and Vermilinguas, pp. 419–427. Smithsonian Inst. Press, Washington, D.C.; Fitch et al. 1952. J. Mammal. 33:21–37; Kalmbach 1943. The Armadillo: Its Relation to Agriculture and Game. Texas Game, Fish and Oyster Comm. Bull.) but none reported Mole Salamanders specifically. Each of these reports concluded that amphibians are a very small portion of the total diet of armadillos (less than 2% by volume) and that a majority are taken during the cooler parts of the year when most salamander species migrate. However, the evidence reported here suggests that as nine-banded armadillos continue to expand their geographic range they may increasingly affect ambystomatid populations in new regions of the southeastern United States, especially when inadvertently aided by drift fences at research sites. Although researchers probably trap and remove most bothersome predators during sampling periods, potential for abnormally high predation remains if drift fences are left partially erect when inactive.

Submitted by **DEAN A. CROSHAW**, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA and Department of Biological Sciences, University of New Orleans, New Orleans, Louisiana 70148, USA (e-mail: croshaw@srel.edu).

PLETHODON ALBAGULA (Western Slimy Salamander). **BROODING DEFENSE BEHAVIOR AND OOPHAGY.** Salamanders of the genus *Plethodon* are known to brood egg clutches (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington D.C. 587 pp.; Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.). Aggressive defense behavior while brooding has been documented in *P. cinereus* (Redback Salamander) numerous times (Bachmann 1984. Herpetologica 40:436–443; Highton and Savage 1961. Copeia 1961:95–98). Although defensive brooding behavior has been documented in other plethodontids (see Bachmann 1984, *op. cit*., for citations), it has not been reported in *P. albagula*. Herein, we report four instances of brooding defense behavior by *P. albagula* and document oophagy in this species.

Spillway Mine (Garland Co. Arkansas, USA) is a sanctuary for brooding female *Plethodon albagula*. This 149-m linear abandoned mineshaft, located in the Ouachita National Forest in south-central Arkansas, is utilized by a number of *P. albagula* females each late summer and fall (August–December). Trauth et al. (*in press*, Herpetol. Nat. Hist.) reported on brooding postures and nest site fidelity of the females using this mineshaft. Several lone females, not attending an egg clutch, have been observed to freely roam the mine during the brooding season and could potentially be marauding egg clutches.

On 4 Oct 1984, a female *P. albagula* brooding a clutch of 19 eggs (76 m from mine entrance) was attacked by a lone adult female. Upon attack, the attacker approached the clutch from an unguarded side and violently pulled a single egg from the clutch. The attacking female retreated while the brooding female repeatedly bit the side and tail of the attacker after chasing it into a crevice. The bites were made as the intruder made one bite and released quickly. Afterwards, the brooding female returned and wrapped herself around her clutch. The second instance occurred on 13 Sept 2002, as a lone female attempted to inspect an egg clutch (99 m from mine entrance) attended by a brooding female. As the lone female traveled in front of the brooding female, she was inflicted with a series of bites to the tail until the lone female quickly retreated and settled 0.2 m from the attack site. The final instances occurred 23 Oct and 18 Nov 2004. On 23 Oct, a brooding female (55 m from mine entrance) attacked a pair of calipers and, subsequently, the researcher's finger as egg diameter measurements were being taken. The female proceeded to inflict three separate bites on the calipers until the researcher retreated. The second instance from the same female occurred on 18 Nov where the female inflicted one bite to the researcher's hand. These occurrences suggest brooding defense behavior is common in the wild for *P. albagula*.

On 5 Nov 1999, a female *P. albagula* was collected from Spillway Mine. Upon necropsy, the female contained three eggs in her digestive tract. During Fall 1999, 31 females were brooding clutches in the abandoned mine shaft and, through photo identification, this female was not determined to be a female with a clutch. Thus, to our knowledge this is the first documented instance of oophagy in *P. albagula*.

TRAUTH,** Department of Biological Sciences, PO Box 599, Arkansas State University, State University, Arkansas 72467, USA (e-mail [JRM]: joemilanovich@yahoo.com; [SET]: strauth@astate.edu); and **DAVID A. SAUGEY**, U.S. Forest Service, PO Box 189, 8607 North Highway 7, Jessieville, Arkansas 71949, USA (e-mail: dsaugey@fs.fed.us).

PLETHODON GLUTINOSUS (Slimy Salamander). **BURROWING BEHAVIOR.** Slimy Salamanders get their name from the sticky substance excreted from their skin when grabbed or roughly handled (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 587 pp.). It is also known that these salamanders frequently inhabit abandoned burrows made by other organisms and shelter underneath rocks and logs. On 17 Sept 2005 in West Davenport, New York (USA) I attempted to capture and measure an adult *P. glutinosus* as it went into a burrow. Upon excavation of the burrow, it was observed that the burrow was L-shaped, shallow (ca. 10 cm deep), non-continuous, and had just enough room to fit the salamander. A thick, cloudy, white, glue-like substance was found completely coating the walls of the burrow. This substance was strong enough to adhere clumps of dirt to my hand making further pursuit of the salamander difficult. Due to the thickness of the substance it was improbable that it was put there during the short period of attempted capture. During the excavation process, the adult *P. glutinosus* remained in the burrow.

This is the first report of *P. glutinosus* layering the walls of a burrow with slime. The slimed walls could be a means of prey capture or be used as an insulating mechanism during times of hibernation.

ology, Hartwick College, Oneonta, New York 13820, USA; e-mail: diefenbachee@hartwick.edu.

TRITURUS MARMORATUS (Marbled Newt). **LIMB ABNORMALITIES.** Herein we report a high occurrence of limb abnormalities in a population of *Triturus marmoratus*. Data were gathered during 2000–2003 and 2005, while we were investigating the orientation behavior of this species (Diego-Rasilla and Luengo 2002. J. Ethol. 20:137–141; Diego-Rasilla and Luengo 2004. Behav. Ecol. Sociobiol. 55:556–560).

A temporal pond 270 m^2 situated in Valdeajos (Burgos, northern Spain; 42º44' 32 N, 3º54'41"W; 1040 m elev.) was monitored for Marbled Newts during the spring. This eutrophic pond, constructed for cattle use and surrounded by an agricultural landscape, is characterized by high levels of nutrient runoff from agricultural lands and heavy livestock use.

Of the 33 adult newts collected in 2000, one adult male and one adult female had visible abnormalities (6.1 % abnormal). The female newt had seven digits (polydactilia), which were poorly separated and short, indicating missing phalanges (brachydactyly) in its right hind limb. The male had the normal number of metatarsal bones in its right hind limb, but the number of phalanges was reduced (brachydactyly) (see Diego-Rasilla 2000. Bol. Asoc. Herpetol. Esp. 11[2]:88–89).

Fifteen newts were examined in 2001, and one adult male and one adult female appeared abnormal (13.3% abnormal). On the left hind limb of the male, digit IV had a duplicated phalanx (polyphalangy). In the adult female the left hind limb adopted a palette shape, only three digits were present (ectrodactyly), and they were all short (brachydactyly).

Of 27 adults collected 23 March 2002, one adult female had visible abnormalities (3.7% abnormal). Digit II of its right fore limb had a duplicated last phalanx (polyphalangy), and it was albino (Diego-Rasilla et al., submitted).

Twenty-three adult newts were captured on 11 April 2003. In this survey we collected the albino female again which was the only individual having visible abnormalities (4.3% abnormal).

We searched the pond again on 1 May 2005 and collected 18 adult newts. Three were identified as having abnormalities (16.7% abnormal), one of them being the albino female described above. The other two specimens, male and female, had abnormalities in three of their limbs. The adult female had four digits (i.e., four metatarsal bones) in its left fore limb, but the number of phalanges was reduced (brachydactyly); the right fore limb was very short, showing an absence of the proximal portion of the limb, with the foot attached very close to the body and proximal bones that could not be identified (phocomelia). This is phocomelia and not ectromelia because a foot is present, although the foot is abnormal with only three metatarsal bones (ectrodactyly) associated with a reduced number of phalanges (brachydactyly). The female also showed reduced right hind limb elements (brachydactyly), and digit III was rotated about 90º to the left. The male newt showed reduced right and left fore limb elements (brachydactyly); also digit III in its right fore limb was rotated about 90º to the left and showed reduced right hind limb elements (brachydactyly).

These rates of visual abnormalities exceeded the baseline abnormality percentage of 0–2% predicted in amphibian populations (Ouellet 2000. *In* Sparling et al. [eds.], Ecotoxicology of Amphibians and Reptiles, pp. 617–646. Soc. Environ. Toxicol. Chem.). It has been suggested that the composition of landscapes surrounding wetlands affects rates of limb malformation. Particularly, proximity to human associated land uses including agriculture, as is the case in our Marbled Newt population, is associated with an increased risk (Ouellet et al. 1997. J. Wildl. Dis. 33:95–104).

TRITURUS MARMORATUS (Marbled Newt). **ALBINISM**. On 23 March 2002 we collected an albino adult female *Triturus marmoratus* (129 mm TL; 57 mm tail length; 12.2 g) from a temporary pond situated in Valdeajos (Burgos, northern Spain; 42º44'32"N, 3º54'41"W) at an elevation of 1040 m. The albino adult female also exhibited polyphalangy in its right forelimb. After being examined, the belly and dorsal patterns were photographed for identification and the individual was returned to its breeding pond.

The albino female was golden in appearance, whereas all other *T. marmoratus* captured at the pond showed the characteristic color pattern of this species (Barbadillo et al. 1999. Anfibios y Reptiles de la Península Ibérica, Baleares y Canarias. 419 pp.). This albino female had black eyes and a speckled body pattern, however due to the deficiency of melanophores, there were no greenish or black colors. The dorsal surface had a golden base color with dark spots showing poorly defined edges. Dorsally, the individual showed a golden, poorly defined, dorsal stripe. Golden shades were clearest on the limbs and on the ventral surface of the abdomen, thorax, and head because dark spots scarcely appeared on these surfaces. The ventral surface of the abdomen showed a thinner epidermis, and it was possible to see the intestines through the skin.

In a subsequent survey at the same pond on 11 April 2003, we collected the albino female for a second time (132 mm TL; 60 mm tail; 10.9 g). We searched the same pond again on 1 May 2005 and collected the albino female again (137 mm TL; 64 mm tail; 8.1 g). It seems that selective pressures against albinism in wild *T. marmoratus* may not be strong since this individual survived as an adult animal. Also, it successfully returned in successive years to the same pond, showing strong site fidelity for its breeding pond.

Submitted by **FRANCISCO J. DIEGO-RASILLA, ROSA M. LUENGO** and **L. RODRÍGUEZ-GARCÍA,** Departamento de Biología Animal, Universidad de Salamanca, 37007-Salamanca, Spain (e-mail: fjdiego@herpetologica.org).

ANURA

ASCAPHUS TRUEI (Tailed Frog). **NEST SITE**. Few nest sites of *A. truei* have been reported and the timing of oviposition is relatively unknown. Here I report the first *A. truei* nest site from Mendocino County, California (USA) and also the first site detected within a seep. Karraker and Beyersdorf (1997. Northwest. Nat. 78:110–111) reported the only previously documented site in California on 16 August 1994.

On 3 August 2005, I found an *A. truei* nest site ca. 9 km S of Elk, Mendocino Co., California in the Elk Creek drainage. Twenty-five eggs were attached to the underside of a large cobble (126 × 118 mm) in a seep (0.3 m wide), ca. 6 km inland from the Pacific Ocean. The eggs were in a continuous string and each egg was ca. 6 mm in diameter. The site occurred on private forest land in a west-facing seep with 75% gradient. Overstory vegetation was primarily 40-year old Coast Redwood (*Sequoia sempervirens*) and Douglas-fir (*Pseudotsuga menziesii*), with 89% canopy closure (measured with a densiometer). The nest site was located 1 m above the seep's confluence with a 3rd order fish-bearing stream.

On 18 August, five tadpoles were observed in the seep and there were no unhatched eggs remaining. The five tadpoles measured 15–17 mm TL and had moved as far as 15 cm downstream from the nest site towards the fish-bearing stream. The tadpoles had functioning oral discs and characteristic white tail flags. No predators were observed within the seep, and it appeared as if many tadpoles had moved into the fish-bearing stream prior to the second visit.

Although I do not know if predation of eggs occurred prior to my discovery, the clutch size (N = 25) is consistent with other clutches reported for coastal *A. truei* (Adams 1993. Northwest. Nat. 74:15–18; Karraker and Beyersdorf, *op. cit.*; Noble and Putnam 1931. Copeia 1931:97–101) and further supports the hypothesis that coastal populations have smaller clutch sizes than inland populations.

I thank David W. Ulrich and Christopher A. Morris for their assistance in concluding this work.

GASTROPHRYNE ELEGANS (Elegant Narrow-mouthed Toad). **ABUNDANCE.** *Gastrophryne elegans* is found in Belize, Guatemala, Mexico, and Honduras and is characterized as a species of least concern by the IUCN Global Amphibian Assessment (http://www.globalamphibians.org; accessed 21 July 2005). Nonetheless, *G. elegans* is known from only a few localities in Belize (Meyer and Foster 1996. A Guide to the Frogs and Toads of Belize. Krieger Publ. Co., Malabar, Florida. 80 pp.). McCranie and Wilson (2002. The Amphibians of Honduras. SSAR Contrib. Herpetol. 19, 625 pp.) reported only two localities in Honduras, and Lee (1996. The Amphibians and Reptiles of the Yucatán Peninsula. Cornell Univ. Press, Ithaca, New York. 500 pp.) described it as uncommon. During a 20-month study in the Bladen Nature Reserve (16°33.124'N, 88°42.974'W), southern Belize, I observed *G. elegans* on several occasions. Here I present observations of unusually high abundance during April 2000, the driest month of the study.

From 24–28 April 2000, I observed many individuals of *G. elegans* during diurnal and nocturnal visual encounter surveys along an unpaved road in tropical evergreen forest. The road was recently graded and large clumps of soil were exposed on the surface. On 28 April 2000, during a 10-min. visual encounter survey that began at 1918 h, I observed 10 adults active on the road surface. The substrate was damp, but there was no standing water. On the same night at another location on the road, I observed 17 *G. elegans* over a period of 10 min. starting at 2005 h. The soil at this site was dry, and there was no standing water. Such abundance was not observed in forested sites distant from the road during April 2000 or during any other survey during the study period. These observations of aboveground activity are unusual because April 2000 was the driest month of my 20-month study, with only 9.6 mm of precipitation. This small quantity of rain fell during the first half of the month and therefore could not be a factor influencing these observations. Because *G. elegans* is fossorial, I suspect that the frogs were unearthed by the recent roadwork and were unable to obtain cover in the extremely dry and hard soil. These observations suggest that although infrequently encountered, *G. elegans* may exist at locally high densities.

PHYLLOMEDUSA ROHDEI (Mertens' Leaf Frog). **DIET**. *Phyllomedusa rohdei* is endemic to the Atlantic Rainforest of southeastern Brazil. No information exists on food habits of this species. Herein we provide data on the stomach contents of 20 individuals (17 males and 3 females) of *P. rohdei* collected by one of us (RLT) on 20 January 2003, between 2000 and 2300 h, in the municipality of Nova Venécia (18°42'S, 40°30'W), Espírito Santo State, southeastern Brazil. Males ranged from 33.1 to 41.9 mm SVL (mean 37.2 ± 2.5 mm), and females from 42.1 to 45.0 mm SVL (mean 43.7 ± 1.5 mm). The diet was comprised of various arthropods, without a marked dominance of a single prey type, though stoneflies (Plecoptera) were the most important items overall. This is somewhat unexpected, as stoneflies have not been reported in the diets of other *Phyllomedusa* (Duellman 1978. Univ. Kansas Mus. Nat. Hist., Misc. Publ. 65:1–352; Duré 1999. Herpetol. Rev. 30:92; Santos et al. 2004. Iheringia, Sér. Zool. 94:433–438; Vaz-Silva et al. 2004. Herpetol. Rev. 35:160). Data

TABLE 1. Prey in the stomach contents of *Phyllomedusa rohdei* (N = 20) from Nova Venécia, Espírito Santo, southeastern Brazil. F = frequency of occurrence; N = number of individual prey items; M = prey wet mass (in mg).

from these studies, as well as that presented here, suggests an opportunistic diet consisting of a wide variety of arthropods, with frequent consumption of relatively large, soft-bodied prey such as orthopterans, spiders, cockroaches, and larvae. This report reinforces the notion that *Phyllomedusa* tend to be opportunistic predators. The presence of stoneflies and dragonflies (Odonata) in the diet suggests that *P. rohdei* in this population may frequently forage at the margins of water bodies.

We thank Aílson Anastacio, Gladstone I. Almeida and José Alberto P. Schineider for their assistance during fieldwork.

José Ruschi 4, 29650-000, Santa Teresa, ES, Brazil; and **DAVOR VRCIBRADIC**, Departamento de Ecologia, Instituto de Biologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, 20550-011, Rio de Janeiro, RJ, Brazil.

***PHRYNOHYAS* SPP**. (Golden-eyed Treefrogs). **PREDATION**. The genus *Phrynohyas* includes seven species distributed across the lowlands of Mexico, Central and South America east of the Andes, south to northern Argentina (Frost 2004. Amphibian Species of the World: an Online Reference. http://research.amnh.org/herpetology/amphibia/index.html; August 2005). These species are known to produce a secretion that can be irritating to skin and mucous membranes (Rodríguez and Duellman 1994. Univ. Kansas Nat. Hist. Mus. Special Publ. 22:1–80). Herein we report predation on two species of *Phrynohyas* (*P. mesophaea* and *P. venulosa*) by the snakes *Liophis* and *Leptophis*.

A *Liophis miliaris* (female; 65 cm TL) was collected during 1994 in Matinhos Municipality, Paraná State, Brazil (25°45'S, 48°30'W, Atlantic Forest, Restinga habitat). Stomach analysis revealed a partially digested *P. mesophaea*, swallowed headfirst. Stomach analysis of a *Liophis poecilogyrus* (female; 57.7 cm TL) collected during 1998 in Jussara Municipality (23°37'7"S, 52°28'10"W, Araucaria Forest) revealed a partially digested *P. venulosa*. On 17 March 2004 in Céu Azul Municipality (25°20'S, 53°46'W, Semi-deciduous Seasonal Forest) a VHS video recorded 1.5 m TL *Leptophis ahaetulla* resting on the roots of a tree at a river edge. As the collector approached, the snake exhibited the typical open-mouth threat display (Achaval and Olmos 2003. Graphis Press, Montevideo. 136 pp.) and then regurgitated a *P. venulosa* female covered in a thick mucous. *Liophis miliaris*, *L. poecilogyrus*, and *Leptophis ahaetulla* are known to include anurans in their diet (Michaud and Dixon 1989. Herpetol. Rev. 20:39–41; Pardo 2003. Herpetol. Rev. 34:231–232; Teixeira and Porto 1991. Herpetol. Rev. 22:132).

Voucher specimens, with prey items, were deposited in the Herpetological Collection of the Museu de História Natural Capão da Imbuia, Curitiba, Paraná, Brazil (MHNCI 8266, *Liophis poecilogyrus*; MHNCI 9732, *Liophis miliaris*). Video images of the *Leptophis ahaetulla* are also available in the herpetological laboratory at the same institution. We thank Reginaldo A. Machado for specimen identification, Paulo S. Bernarde for the revision of the text, and Beto Sporkens for the VHS image. We also thank Fernando C. Straube for the contribution of his field notes.

RANA BOYLII (Foothill Yellow-legged Frog). **REPRODUCTION**. Recent work on explosive-breeding anurans has provided increasing evidence of male competition (e.g., *Agalychnis callidryas*, D'Orgeix and Turner 1995. Mol. Ecol. 4:505–508; *Rana dalmatina*, Lodé and Lesbarrères 2004. Naturwissenschaften 91:44–47; *Rana temporaria*, Vieites et al. 2004. Nature 431:305–308). However, evidence for male competition is sparse among North American ranid frogs, even for western species that exhibit explosive breeding, including *Rana boylii*. Hence, we provide observations from western Oregon (USA) indicating male competition in *R. boylii*.

These observations were made on 22 June 2004, during the oviposition period of the northernmost extant population of *R. boylii*. Elsewhere (Rombough and Hayes 2005. Herpetol. Rev. 36:163–164), we detail the location (on the South Santiam River) and provide a site description. Oviposition takes place exclusively in a few off-channel pools and troughs with reduced flow velocities that reduce the likelihood of egg scour (Rombough 2002. Status of the Foothill Yellow-legged Frog [*Rana boylii*] in the South Santiam River, Linn County, Oregon. Report to the Oregon Department of Fish and Wildlife. 42 pp.; but also see Kupferberg 1996. Ecol. Appl. 6:1332–1344; Lind et al. 1996. Herpetol. Rev. 27:62–67). Frogs discussed herein were captured for measurement after oviposition and after interactions between frogs were completed.

Between 1010 and 1045 h, CJR observed an amplectic pair (male: 51.5 mm SVL, 11.5 g; female: 59.0 mm SVL, 15.7 g) during their entire oviposition sequence, also described elsewhere (Rombough and Hayes 2005. Northwest. Nat. 87:157–160). During the oviposition process (including substrate preparation and egg deposition), at least seven other male frogs took up positions within 150 cm. Typically, males sat emergent in shallow water (< 2 cm) or on the bottom, near some sort of substrate irregularity (e.g., a cobble or bedrock ledge) in deeper water (> 10 cm). One of these males (No. 1; 56.5 mm SVL, 13.2 g) remained within 5–11 cm of the pair the entire time. This male never touched the pair nor got closer than 5 cm, even during egg deposition. He often hid under cobbles or sat underwater nearby, always facing the amplectic pair. As soon as the female had finished laying, No. 1 shot forward and rammed the left side of the pair, hitting mostly the male. Immediately after he contacted the pair, No. 1 gave a frog kick that caused the pair to swivel away from the mass. Then, holding the pair with his front limbs, he lowered his vent to the egg mass and held it there for ca. 60 sec. The pair then moved and started to swim, and No. 1 grappled at the male in the pair, but was shaken off, and the pair swam away. When the pair were just over 20 cm from the egg mass, they broke apart and each swam off in differ-

ent directions. After the pair separated, the formerly paired male grabbed No. 1 and began amplexing him, even though he struggled to escape. At this point, all three frogs were captured and measured. Over the period of observation, the paired frogs initially traveled ca. 2 m.

A second amplectic pair (male 53 mm SVL, 12.8 g; female 74.4 mm SVL, 35.5 g), observed entering the oviposition area at 1055 h, just after capture and release of the frogs described above, was also followed closely by two additional male frogs (No. 2: 54.0 mm SVL, 11.0 g; No. 3: 67.5 mm SVL, 20.0 g). These males behaved in a manner similar to No. 1, but approached much more closely and frequently made contact with the pair. On at least 10 occasions, they grappled at the paired male or the hind leg of the female. Usually, the female would forcefully kick the intruder(s) away, but occasionally both amplectic partners or rarely, only the male, would do the kicking. The unpaired males also continuously rushed, grabbed, and amplexed one another. Rushes would be made from a near touching position to distances > 45 cm away, with smaller males grabbing larger males and vice versa. Often, release following an amplectic grab would be immediate, without a sound. However, for at least one third of (> 30) such grabs, one male amplexed a second male for between 30 sec and 2 min, even while the other forcefully tried to escape, swimming a meter or more and flipping upside down (often with the frogs' bright yellow-and-white undersurfaces visible for at least 30 sec). These entire sequences occurred without any apparent vocalization. On at least three occasions, one male even grabbed another male facing backwards (i.e., the frogs were facing opposite directions). Although individual males would swim to the surface regularly (more frequently than the male/female pair) to gulp air (and then swim quickly back to the bottom to hide), pairs of males were also observed to surface together to gulp air on multiple occasions. This behavior continued for 3 hours, until the frogs were captured and measured.

Non-vocal competition for females is known for a number of anuran species, and is most common among explosive breeders (Wells 1977a. *In* Taylor and Guttman [eds.], The Reproductive Biology of Amphibians, pp. 233–262. New York, Plenum Press; Wells 1977b. Anim. Behav. 25:666–693). Over five years of study, the *R. boylii* at this location have completed most of their breeding activity within a week. At breeding sites, males outnumber females by an average of 7 to 1, and observations of breeding frogs indicate that females are amplexed by the first male they approach (CJR, unpubl. data). Because frogs in male-only aggregations often grab one another, tactile identification (rather than auditory or visual identification) of a suitable partner appears to be an important cue for stimulating amplexus (Noble and Aronson 1942. Bull. Am. Mus. Nat. Hist. 80:127–142; Wells 1977b, *op. cit.*).

While physical displacement of a competing male is obvious, male competition may not involve much, if any direct contact. In particular, the behavior performed by male No. 1 (holding his vent over freshly laid eggs) strongly resembles the "clutch piracy" behavior of *R. temporaria*, in which pirate males fertilize the eggs of another frog pair, either during or after laying (Vieites et al., *op. cit.*). Confirmation of this hypothesis requires genetic data, but our observations imply that such competitive behavior may be more widespread among ranid frogs than previously thought.

RANA CATESBEIANA (American Bullfrog). **MORTALITY**. On 25 Aug 2005, I found a recently deceased adult male Bullfrog (snout–urostyle length ca. 16.5 cm) with the posterior half of an 11.5 cm TL Brown Bullhead (*Ameirus nebulosus*) protruding from its mouth. I made this observation along the edge of a drying pool in a blackwater creek swamp on Fort Stewart Military Installation, Long Co., Georgia, USA. The 4 × 6 m turbid and fetid pool was littered with the carcasses of dozens of Brown Bullheads and centrarchids that had recently died, likely due to anoxic conditions. A few live fish occasionally surfaced to gulp air. As seen in Fig. 1, the frog evidently choked on the fish while attempting to swallow it. Whether the dorsal or pectoral spines of the fish prevented the frog from swallowing the fish or whether the frog choked solely because of the large size of the prey is unknown. To my knowledge this is the first observation of a Bullfrog choking while attempting to prey on a bullhead.

I thank John G. Palis for reviewing this note.

FIG. 1. Adult American Bullfrog (*Rana catesbeiana*) that died while attempting to eat a Brown Bullhead (*Ameirus nebulosus*).

TESTUDINES

PHRYNOPS HILARII (Hilaire's Side-necked Turtle). **FEEDING BEHAVIOR**. *Phrynops hilarii* posseses a prominent pair of barbels in the gular region that function as mechanoreceptors and are used during mating behavior (Bager 1997. M.S. Thesis. Universidade Federal do Rio Grande do Sul. Rio Grande do Sul.

Brazil. 110 pp.; Winokur 2005. J. Morphol. 172:59–74; Legler 1993. *In* Glasby et al. [eds.], Fauna of Australia, vol. 2, pp. 108–119. Canberra). The barbels are beige in color, matching the turtle's gular coloration, but have a conspicuous black ring at the base. Here we present a description of the species' use of the barbels in feeding, specifically in attracting and capturing fishes.

Captive-hatched *Phrynops hilarii* hatchlings (mean carapace length = 42.4 ± 3.25 mm; N = 111) were kept in a 500-L aquarium (30–40 turtles per tank) with a water depth of 50 cm, a small dry area, and a quantity of floating aquatic macrophytes. Hatchlings were fed live fish and pieces of beef. Thirty juvenile lambari (*Astyanax* sp.), a characid fish, with a mean length of 3.1 ± 0.5 cm, were placed in the tank weekly.

The *P. hilarii* hatchlings were observed using a unique feeding strategy whereby they aligned themselves with submerged *Pistia stratiotes* roots or stalks or on the terrarium substrate itself by extending their anterior limbs forward and hind limbs backward. Their necks remained fully extended, which is contrary to the strategy used by "fishing" *Chelus fimbriatus*, which keep the neck partially contracted (Pritchard 1984. Symp. Zool. Soc. London 52:87–110; Lemell et al. 2002. J. Exp. Biol. 205:1495–1506). The head is jerked in short and quick movements, which causes the barbels to move. It was observed that the black circle at the barbel's base gives an impression of discontinuity between the turtle's gular region and the barbel, hence it may resemble a small invertebrate to a passing fish. Juvenile fish that approach a *Phrynops hilarii* hatchling's head and try to bite at the barbels are often captured, though the efficiency of this strategy was not quantified.

The fish were not quickly swallowed, probably due to their comparatively large size. A hatchling *P. hilarii* that captured a fish was soon approached by other hatchlings, starting a competition for the resource involving agonistic behavior. Such behavior included bites to the anterior and posterior limbs.

The monitored hatchlings did not have any contact with juvenile or adult exemplars, making it unlikely that the observed feeding behaviors were learned. Systematic observations in a natural environment have not been made, but on several occasions we observed the same postures in juvenile and adult specimens submerged in rivers and wetlands, though a complete behavioral sequence with prey ingestion has not yet been noted.

Submitted by **ALEX BAGER, LAURO J. C. BARCELLOS**, and **SÉRGIO R. N. PIEDRAS**, Universidade Católica de Pelotas. Laboratório de Manejo e Conservação Ambiental, Rua Félix da Cunha, 412, Pelotas, RS, 96010 000, Brazil (e-mail: abager@uol.com.br).

RHINOCLEMMYS FUNEREA (Black Wood Turtle). **REPRODUCTION**. The reproductive biology of *R. funerea* is inadequately known. Courtship and mating behavior, and egg-laying have been described by Iverson (1975. J. Herpetol. 9:249–250) and Merchán and Mora (2000. Reptilia 26:31–38). Nevertheless, the reproductive season, clutch size, and egg and hatchling size are poorly known. This note provides additional data on reproduction in Costa Rica.

Between November 1999 and December 2001 we found nine egg clutches of *R. funerea* in the Reserva Zoo Ave (Alajuela Province, Costa Rica). Mean clutch size was 4.3 eggs (range 1–7, SD = 1.94). Egg laying occurred between May and October, with a peak in May (44.4% of the sample). The incubation period ranged from 81 to 106 days (mean 92.3) at a temperature of 28ºC. Twenty-five of 40 eggs produced hatchlings. Data for 40 eggs are as follows. Mean mass = 49.6 g (range 37.3–60.0 g, SD = 6.0); mean length = 64.2 mm (range 55.3–76.1 mm, SD = 5.5); mean width = 34.9 mm (32.0–38.1 mm, SD = 1.3). Hatchling measurements are shown in Table 1.

TABLE 1. Data on 25 hatchlings of *Rhinoclemmys funerea*. Weight in grams, rest of measures in millimeters. St. Dev: Standard Deviation. SCL: Straight Carapace Length. SCW: Straight Carapace Width. SPL: Straight Plastron Length. SPW: Straight Plastron Width.

	N	Mean	Minimum	Maximum	St. Dev.
Weight	25	32.4	24.9	38.5	4.12
SCL	15	56.5	50.8	65.0	3.75

CROCODYLIA

CROCODYLUS ACUTUS (American Crocodile). **MIGRATION**. American Crocodiles require an elevated, well-drained substrate for nesting (Mazzotti 1989. Bull. Mar. Sci. 44:220–228). In Florida, human-made nesting areas along canal banks (berms) at Crocodile Lake National Wildlife Refuge, East Cape Canal in Everglades National Park (ENP), and the cooling canal system at Turkey Point Power Plant provide near ideal nesting conditions, with year-round habitat adjacent or in close proximity to nesting sites. In contrast, nesting areas and nursery habitat in Florida Bay within ENP are often separated by kilometers, necessitating migrations by females to nest sites (Kushlan and Mazzotti 1989. J. Herpetol. 23:1–7). Mazzotti (1983. The Ecology of *Crocodylus acutus* in Florida. PhD dissertation, The Pennsylvania State University, University Park, Pennsylvania. 161 pp.) reported seasonal movements of 5–15 km from year-round habitat to nesting beaches. *Crocodylus acutus* at other locations across its range have been suspected to exhibit this behavior as well; however, to date no such reports have been published. Here we report the longest distance recorded yet for migration of one female *C. acutus* to a nest site.

During the 2003 nesting season, a crocodile nest was reported on Lower Matecumbe Key (24°52'30.4"N, 80°41'54.8"W, datum: WGS84; elev. 0.5 m) in the yard of a private estate. On 22 September 2003, the nesting female crocodile (272 cm total length, 70 kg) was captured along with nine hatchlings in a pond adjacent the nest. All individuals were measured, weighed and given a

unique scute mark as described by Mazzotti (1983, *op. cit.*). On 18 November 2004, during a spotlight survey in the Flamingo district of ENP, the female was recaptured (283 total length, 72 kg) in a creek between Henry Lake and Monroe Lake (25°11'23.2"N, 80°45'11.5"W, datum: WGS84; elev. 0.5 m), a straight-line distance from the nest site of over 35.5 km. The female likely traveled though several creeks and along a chain of islands in ENP, possibly passing areas with suitable nesting habitat before reaching her chosen nest site at Lower Matecumbe Key. We were able to identify this female at active nest sites on Lower Matecumbe Key in 2004 (nest failed) and 2005 (nest produced 20 hatchlings). Reuse of nest sites by individual females has been surmised (Thorbjarnarson 1988. Bull. Florida State Mus., Biol. Sci. 33:1–86) but is difficult to document. Mazzotti (1983, *op. cit.*) reports the only data concerning reuse of an individual nest over consecutive years for *C. acutus*.

We thank John Craig Eaton, Sally Horsfall Eaton, and Billy Bishop for bringing this nest to our attention, for providing us with access to their property, and for their willingness and appreciation of what it means to live with American Crocodiles in their backyard.

LACERTILIA

AGAMA AGAMA AFRICANA (African Rainbow Lizard). **REPRODUCTION**. Wilson and Porras (1983. Univ. Kansas Mus. Nat. Hist. Spec. Publ. No. 9:1–89) first reported *Agama agama africana* in Florida. Subsequently, Enge et al. (2004. Florida Sci. 67:303–310) documented five allopatric populations in Broward, Charlotte, Martin, Miami-Dade, and Seminole counties (Florida), and reported gravid females in late May. Herein, we augment reproductive data in Florida for this non-native species.

On 7 April 2006, we collected eight *Agama a. africana* from two nearby sites under SR 17 in Punta Gorda, Charlotte County, Florida: at Lavilla Road (26°56'22.2"N, 82°01'38.2"W, datum: NAD83; elev. < 1 m) and at Florida Street (26°56'20.4"N, 82°01'28.9"W, datum: NAD83; elev. < 1 m). Specimens were collected using live crickets as bait after Krysko (2000. Carib. J. Sci. 36:162) and deposited in the Florida Museum of Natural History (FLMNH), University of Florida collection (UF). All females (N = 5, UF 147111–14, 147116) collected were gravid (i.e., contained shelled oviductal eggs) and ranged in size from 108.0–122.5 mm SVL. Mean clutch size of oviductal eggs was 7.6 ± 0.4 mm SE (range = 7–9), mean length of oviductal eggs was 19.6 ± 0.2 mm (range = 15.1–23.8, N = 38), and mean length of vitellogenic (i.e., yolk-producing) follicles was 5.7 ± 0.2 mm (range = 3.7–7.7, N = 49). Enge et al. (*op. cit.*) mistakenly reported clutch sizes to include both oviductal eggs and vitellogenic follicles. We recalculated their data to include mean clutch size of oviductal eggs as 8.7 ± 0.4 mm SE (range = 5–12, N = 17), mean length of oviductal eggs as 14.1 ± 0.3 mm (range = 8.6–21.2, N = 146), and mean length of vitellogenic follicles as 5.8 ± 0.2 mm (range = 3.8–8.8, N = 39). In Africa, *A. a. africana* oviposits multiple clutches consisting of 3–9 eggs each, with five or six eggs being most common (Daniel 1960. Copeia 1960:94–97; Harris 1964. The Life of the Rainbow Lizard. Hutchinson Tropical Monographs, London, 174 pp.). Our data for female *A. a. africana* from Florida are similar to those in their native range. Enge et al. (*op. cit.*) further suggested that their oviductal eggs found at the end of May were from a second clutch that year. Our larger oviductal eggs found in April support their findings and illustrate that reproduction in *Agama a. africana* occurs in as early as April in Florida, but breeding takes place even earlier. Besides oviductal eggs, we identified at least two size classes of vitellogenic follicles, suggesting the potential for females to oviposit three clutches annually. Although the ecological impacts of *Agama a. africana* on native Florida wildlife is unknown, the fecundity exhibited by this species secures its ecological status as an established non-native species.

We thank George Zug and Kevin M. Enge for helpful suggestions on this note.

Submitted by **TRAVIS K. BLUNDEN** and **KENNETH L. KRYSKO**, Florida Museum of Natural History, Division of Herpetology, University of Florida, Gainesville, Florida 32611, USA; e-mails: tblunden@ufl.edu and kenneyk@flmnh.ufl.edu.

ANOLIS CUVIERI (Puerto Rican Giant Anole). **REPRODUCTIVE ECOLOGY**. Mating systems that include pair-bonding in lizards are rare and only well documented in few long-lived species, mostly scincids (*Eumeces laticeps*, *Niveoscincus microlepidotus*, *Tiliqua rugosa*; Pough et al. 2001. Herpetology, 2nd ed., Prentice Hall, Upper Saddle River, New Jersey. 612 pp.). For example, in the long-lived Australian skink *Tiliqua rugosa* (ca. 30 cm SVL), pair-bonding can reduce energetic costs associated with finding a mate during the breeding season and increase mating success (Bull 1994. *In* Vitt and Pianka [eds.], Lizard Ecology, pp. 159–174. Princeton Univ. Press, Princeton, New Jersey). In this species, energetic costs are reduced by mates by following each other into the same retreat and sleeping sites, thus reducing the time and effort to find mates during the breeding season (Bull, *op. cit.*).

In Puerto Rico, pair-bonding has been suggested for the Puerto Rican Dwarf Anole, *Anolis occultus* (ca. 3.4 cm SVL), based on observations of sleeping pairs in nature (Gorman 1980. Carib. J. Sci. 15:29–31). Unfortunately, the reproductive phenology of *A. occultus* is largely unknown, limiting interpretation of the adaptive significance of this behavior. Here, we document sleeping pair behavior in the Puerto Rican Giant Anole, *Anolis cuvieri*, a large-sized anole (ca. 12.5 cm SVL) that frequently occurs in the forest canopy and sub-canopy (Reagan 1996. *In* Reagan and Waide [eds.], The Food Web of a Tropical Rain Forest, pp. 321–345. The University of Chicago Press, Chicago, Illinois; Rivero 1998. The Amphibians and Reptiles of Puerto Rico, 2nd ed., revised. Editorial de la Universidad de Puerto Rico, San Juan, Puerto Rico. 510 pp.). *Anolis cuvieri* is widely distributed in forests throughout Puerto Rico, especially in the karst (limestone) habitats, but very little is known about its reproductive ecology. We interpret the possible adaptive significance of sleeping pair behavior to the species' reproductive phenology and population dynamics based on monthly samples obtained over a year.

Between 2130 and 2200 h on 20 October 2001, NRL found a sleeping pair of adult *A. cuvieri* (FIG. 1a) at a height of 2.2 m on a small (ca. 1-cm diam. twig) of *Quararibea turbinata*, an evergreen tree that can reach 6 m or more in height (Little and Wadsworth 1989. Common Trees of Puerto Rico and the Virgin Islands. U.S. Forest Service, Department of Agriculture, Washington. Agricultural Handbook No. 249. 556 pp.). This observation was made on a karst hillside in Sabana Seca (18°25'21"N, 66°11'37"W, datum: WGS84; elev. 25 m), Toa Baja, northern coastal Puerto Rico. This site is classified as Subtropical Moist Forest with an average annual rainfall and temperature of 1700 mm and 27°C, respectively (Ewel and Whitmore 1973. The Ecological Life Zones of Puerto Rico and the US Virgin Islands. Institute of Tropical Forestry, Río Piedras, Puerto Rico. Forest Service, US Department of Agriculture. Research Paper ITF 18:1–72). Microclimatic conditions at the height of the lizards were 0 km/h wind speed, 24.8°C air temperature, and 96% relative humidity. On a nearby karst valley (ca. 500 m away from the karst hill), NRL found another adult pair sleeping between 2200 and 2300 h on 27 June 2003 on an unidentified liana (ca. 2 cm diam.) at 3.3 m height (Fig. 1b). About a month later (25 July 2003), NRL observed a sleeping pair at 2100 h in the same orientation on this same liana, presumably the same pair. Between the years 2000 and 2003, ARPR also recorded 15 adult male-female pairs of *Anolis cuvieri* sleeping within centimeters of one another at heights between 2.2 m and 15 m in lianas (e.g., *Cissus trifoliata*) and trees (e.g., *Bursera simaruba*, *Quararibea turbinata*, and *Zanthoxylum martinicense*) while conducting nocturnal visual encounter surveys for the Puerto Rican boa, *Epicrates inornatus*, in several karst forests through the island. This suggests that sleeping pair behavior may be more common in *A. cuvieri* than previously recognized.

FIG. 1. Sleeping pairs of adult *Anolis cuvieri* on a tree branch (A) and on a liana (B). Note sexual dimorphism in the tail crest.

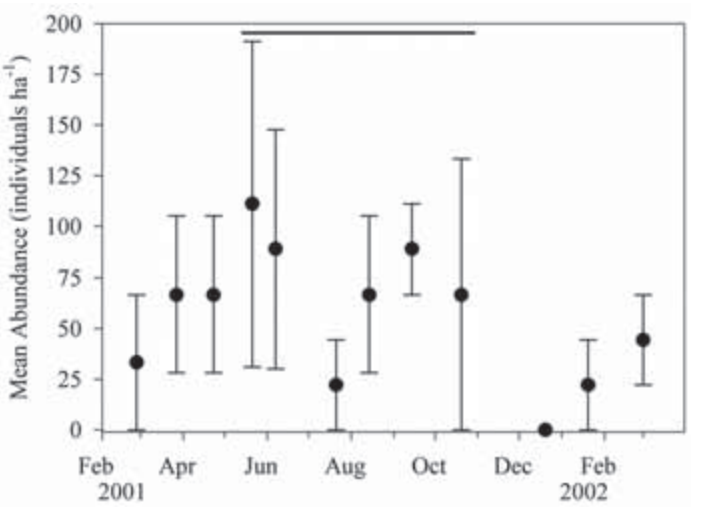

FIG. 2. Mean relative abundance (and standard deviation) of *Anolis cuvieri* from three karst microhabitats in Sabana Seca, Puerto Rico, between February 2001 and March 2002. Horizontal bar on top of graph spans dates when sleeping pairs were observed and the period when recently hatched juveniles were found among microhabitats.

Between February 2001 and March 2002, NRL performed detailed diurnal and nocturnal monthly visual surveys of adult and juvenile *A. cuvieri* along strip plots (50 m long × 3 m wide) in a karst hilltop, hillside, and closed-canopy valley in Sabana Seca, Puerto Rico. Here, both rainfall and temperature are mildly seasonal with most rain occurring May to November, which also represent the warmer months. The mean relative abundance of *Anolis cuvieri* increased to ca. 74 individuals ha^{-1} (range: 0–200 individuals ha^{-1}) during the warmer, wetter months and decreased to ca. 39 individuals ha^{-1} (range: 0–133 individuals ha^{-1}) during the cooler, drier months (December–April; Fig. 2). Recently hatched juveniles were only found during July and October (mean SVL = 4.1 cm, N = 7). Given that eggs of large species like *A. cuvieri* in the tropics may hatch after a ca. 55-day incubation period (R. Andrews, pers. comm.), the period between May and October may represent a distinct breeding season for *A. cuvieri* in Sabana Seca the way it occurs with other sympatric anoles, including native prey species (Reagan, *op. cit.*; Rivero, *op. cit.*).

In Sabana Seca, all *A. cuvieri* sleeping pairs were found only during months in which we found recently hatched juveniles (FIG. 2). Population dynamics and the natural history of the species implies that male and female *Anolis cuvieri* may sleep as pairs as part of a pair-bonding strategy, at least during the warmer, wetter months. The relative large home ranges (275–326 m^2 in males, and 68 m^2 in females: Losos 1990. Carib. J. Sci. 26:65–66; Dial and Roughgarden 1994. Carib. J. Sci. 30:278–279) and the low densities of *A. cuvieri* are consistent with pair-bonding as a strat-

egy to reduce the energetic costs associated with finding mates, and maximize mating success as known in other large-bodied, long-lived lizards with similar demographies (Bull, *op. cit.*).

We thank R. Andrews for information on egg development in anoline lizards. We are indebted to M. Hayes for valuable comments on an earlier version of the manuscript. Research was supported in part by National Science Foundation EPSCoR Fellowship to NRL.

ANOLIS NEBULOSUS (Clouded Anole). **DIET.** *Anolis nebulosus* has been shown to vary its foraging sites and feeding rate with seasonal variations in prey abundance (Lister and García Aguayo 1992. J. Anim. Ecol. 61:717–733). However, no reports exist detailing its diet other than the assumption that it eats arthropods. Here we report observations on the stomach contents of 8 *A. nebulosus* collected during 2003 and 2004 from Chínipas, Chihuahua (N = 4; 27°23'39.9"N, 108°32'36.0"W, datum: WGS84; elev. 469 m), Rancho Jovinos, Chihuahua (N = 1; 27°21'3.5"N, 109°30'10.8"W, datum: WGS84; elev. 428 m); and Arroyo Las Borregas, Chihuahua (N = 3; 27°23'4.3"N, 108°32'21.1"W, datum: WGS84; elev. 470 m) (see Lemos-Espinal et al. 2004. Bull Chicago Herpetol. Soc. 39:164–168; Smith et al. 2005. Bull Chicago Herpetol. Soc. 40:45–51). Of the 8 individuals, 7 contained identifiable stomach contents; one individual had an empty stomach. Table 1 lists the diet items. Numerically, termites were the most important prey, but volumetrically grasshoppers were most important. Interestingly, we found plant material in one stomach. Whether the plant material was intentionally consumed is unclear as it was the only item found in that stomach.

DIBBLE**, Department of Biology, Denison University, Granville, Ohio 43023, USA.

CALLISAURUS DRACONOIDES (Zebra-tailed Lizard). **DIET; CLUTCH SIZE.** *Callisaurus draconoides* is reported to eat a variety of insects and invertebrates (Hotton 1955. Am. Midl. Nat. 53:88–114; Asplund 1967. Am. Midl. Nat. 77:462–475; Pianka and Parker 1972. Copeia 1972:493–508; Smith et al. 1987. Great Basin Nat. 47:175–185) and rarely vegetation (Pianka and Parker, *op. cit.*). Two previous reports on its diet exist for México; Asplund (*op. cit.*) reported on lizards from Baja California, and Pianka and Parker (*op. cit.*) studied *C. draconoides* diet in Sonora. However, the latter authors pooled results with data from Arizona and California, disallowing distinguishing potential regional differences. Thus, we provide data on *C. draconoides* diet exclusively from Sonora, México.

Our observations are based on the stomach contents of 7 *C. draconoides* collected from 22–24 April and 25–27 July 2004 from three localities in Sonora: Valle de Guaymas (N = 3; 28°17'23.0"N, 119°43'0.8"W, datum: WGS84; elev. 103 m), Punta Chueca at Sierra Seri (N = 3; 28°53'20.6"N, 111°59'37.1"W; elev. 75 m), and near Bahía Kino (N = 1; 28°59'43.2"N, 112°7'43.3"W; elev. 48 m; see Smith et al. 2005. Bull Chicago Herpetol. Soc. 40:45–51). All 7 animals contained identifiable stomach contents comprising several invertebrate taxa and some plant material (Table 1). Beetles, found in 5 stomachs, were numerically most important, but volumetrically wasps were most important. One stomach had a small amount of plant material (leaves); as this individual also contained several (5) other prey, leaf ingestion was likely unintentional. Our observations are similar to previous reports on diet in that insects are dominant. However, both Asplund (*op. cit.*) and Hotton (*op. cit.*) found caterpillars important in *C. draconoides* diet, but we observed none. Otherwise, diet composition is very similar to the pooled Mojave and Sonoran Desert sample of Pianka and Parker

(*op. cit*.), to the level of including some vegetation.

Two animals were females (67.1 mm and 65.7 mm SVL), each containing five enlarged ovarian follicles. These clutch sizes are similar to the mean clutch size reported for several populations of *C. draconoides* (Pianka and Parker, *op. cit*.; Smith et al., *op. cit*.).

Specimens were deposited in the Herpetological Collections of the Unidad de Biología, Tecnología y Prototípos (UBIPRO) (JLE11956–11957, 12153, 12334, 13130, 13201, 13377). Collection was conducted under a permit issued to JAL by the Dirección General de Vida Silvestre (DGVS) de la Secretaria del Medio Ambiente y Recursos Naturales.

CNEMIDOPHORUS LONGICAUDUS (NCN). **BODY TEMPERATURE**. *Cnemidophorus longicaudus* is an oviparous lizard inhabiting the hot arid landscape of the Monte Phytogeographic Province in Argentina (Cei 1986. Museo Regionale di Scienze Naturali. Monografie IV. Torino, Italy. 527 pp.). Data on its biology are sparse. Limited study has addressed diet (Belver and Avila 2001. Bol. Soc. Biol. Concepción 72:37–42), time budgets and space use (Videla and Puig 1994. Multequina 3:99–112; Belver and Avila 2001. Bol. Soc. Biol. Concepción 72:31–36; Ontivero 2005. Uso especial y temporal de la estructura de parches de vegetación por *Liolaemus darwinii* [Squamata: Lilaemidae] y *Cnemidophorus longicaudus* [Squamata: Teiidae] en los Medanos grandes, San Juan, Argentina. Tesis de Licenciatura. Universidad Nacional de San Juan. 50 pp.), but information on its thermal ecology is lacking. Hence, we present preliminary data on *Cnemidophorus longicaudus* thermal ecology.

From February 2005 to February 2006, we conducted field work in Médanos Grandes, Departamento Caucete, Provincia de San Juan (38°41'S, 67°48'W, datum: WGS84; elev. 600 m). Located in the Monte Phytogeographic Province, *Bulnesia retama*, *Larrea* sp., and *Prosopis* sp. dominate the flora (Cabrera and Willink 1980. Biogeografía de América Latina. Washington, D.C. 109 pp.). We present data based on 30 individuals observed and 10 captures. To collect these data, we revisited a randomized selection of bushes across the study site. Captures were made by hand, and each individual was measured SVL (to nearest 0.1 mm). Sex was not determined in the field because obvious sexual dimorphism was lacking. For each capture, cloacal (T_c), substrate (T_s) and air (T_a) temperatures were measured (to nearest 0.1ºC) with a rapid-reading Miller-Weber thermometer. We took T_s at the exact point of observation, and T_a 1 cm above the substrate, both immediately following capture. We also recorded microhabitat type for each capture and activity time.

Mean SVL of the 10 captures was 43.6 mm (SD = 9.7, range: 32–58, N = 10). Mean body temperature of the 10 *C. longicaudus* was 36.7°C (SD = 2.2°C, range = 33–41°C). Mean air temperature was 37.7°C (SD = 6.5°C, range = 31.2–48°C). Mean substrate temperature was 39.3°C (SD = 7.3°C, range: 31.4–50°C). Body size appeared unrelated to T_c (Spearman Rank Correlation: r_s = 0.44, P = 0.19, N = 10). Cloacal temperature was not correlated with each of T_s and T_a (Spearman Rank correlation: r_s = 0.04, P = 0.13; r_s = 0.08, P = 0.81, respectively).

Most lizards were observed under vegetation (N = 27) and the remainder in open habitat (N = 3). The activity of *C. longicaudus* was unimodal, the first active lizards were sighted at 0900 h. Thereafter, number of active lizards increased until reaching a maximum of 11 individuals between 1300 and 1400 h; animals disappeared before 1500 h.

The mean body temperature of *C. longicaudus* is similar to *C. ocellifer* (36.5°C), *C. abaetensis* (36.7°C) in Restinga of Dunas do Abaeté (Dias and Rocha 2004. J. Herpetol. 38:586–588), *C. lemniscatus* (37.6°C) in Lavrado and Curuá-Una (Vitt et al. 1997. Copeia 1997:745–757) and *C. littoralis* (38.6°C) in Restinga de Jurubatiba, Macaé (Hatano et al. 2001. Rev. Brasil. Biol. 61:287–294). These similar body temperatures might reflect a conservative thermal physiology in the genus.

CROTAPHYTUS COLLARIS (Eastern Collared Lizard). **COMMUNAL HIBERNATION; DISPERSAL.** Lizards living in temperate climates often hibernate in subterranean burrows where they sometimes aggregate (Ruby 1977**.** Herpetologica 33:322–333). As part of ongoing mark-recapture studies at Arcadia Lake (AL), Oklahoma, USA, on 27 March 2005 we discovered a hibernaculum on a south-facing rocky slope when a newly emergent mud-covered male retreated into a tunnel-like opening (6 cm wide) leading into a burrow beneath a rock. Removal of the rock caused this unidentified male to flee, revealing a bowl-shaped chamber (9.1 cm deep and 20 cm wide) unlike the J-shaped hibernaculum previously described for collared lizards at AL (Baird 1999. Herpetol. Rev. 30:227). Within this same burrow, we also found a two-year old male with his head and torso buried, but his hind limbs and tail exposed. The same burrow also contained two females (a two-year old and a one-year old) that were both tightly buried tail-first within the soil. The one-year old female was buried 13 cm below ground inside a 6 cm long horizontal cavity. Although all in the same burrow, these lizards were separated from one another by a mixture of sandy soil and pebbles. We also found one empty lizard eggshell within the burrow.

Mapped sightings revealed that these three identified lizards moved outside of their 2004 home ranges to hibernate even though burrowing sites similar to the occupied one are abundant throughout the homogeneous rock habitat at AL (Baird and Sloan 2003. Ethology 109:879–894). Only the first (25 April) and last (2 August) captures of the two-year old male in 2004 were within 10 m

of the hibernaculum, whereas the nearest border of his 2004 home range (based on 25 census sightings) was 62 m away. The proximity of the first and last sightings to the burrow suggests that this male may have used this location as a hibernaculum during the winter of 2003–2004, established a home range distant from it during the following spring, and then returned to hibernate in the same burrow over the 2004–2005 winter. Such interseasonal fidelity to hibernacula is documented for other lizards (Elfstrom and Zucker 1999. J. Herpetol. 33:240–248). The territory defended by this male as a two-year old in 2005 was six times larger than, and overlapped only 5% of his 2004 home range, but included the hibernaculum. Although the overlap of the home ranges occupied by the two-year old female during 2004 and 2005 was high (73%), neither included the hibernaculum, which was 26 m from her 2004 and 2005 home ranges, respectively. We first captured the one-year old female as a recent hatchling in August 2004, 126 m from the hibernaculum. Although we sighted this female only three times in May 2005, she dispersed as far as 68 m from the burrow.

Ours represents the second report in *C. collaris* of communal hibernation involving lizards of two generations as well as remnants of eggs (Legler and Fitch 1957. Copeia 1957:305–307). Because adults generally enter hibernacula before young hatch, the newly emerged juvenile must have located this burrow following hibernation of the three adults, which may suggest that conspecific cues are used to orient to communal burrows. Ours, along with one previous observation of collared lizard eggshells within hibernacula (Legler and Fitch 1957, *op. cit.*) suggests that this species uses the same burrows for over-wintering and nesting. Communal hibernation may have thermal advantages, or may be a consequence of limited suitable burrow sites (Gregory 1982. *In* C. Gans and H. Pough [eds.], Biology of the Reptilia Vol. 13, pp. 53–154. Academic Press, New York). Because we found each lizard surrounded by soil rather than in direct physical contact with conspecifics, thermal advantages seem unlikely in our observation. Even though similar burrowing sites are abundant in the human-constructed habitat at AL, they are much less abundant in the rocky substrate that is naturally inhabited by collared lizards (Baird and Sloan 2003, *op. cit.*). Therefore, limitation of suitable sites remains a viable hypothesis that may explain communal hibernation in this species.

We thank the Joe C. Jackson College of Graduate Studies and Research at the University of Central Oklahoma for funding, J. Curtis for technical assistance, and W. Parkerson of the United States Army Corps of Engineers for access to the AL study site.

Submitted by **JENNIFER L. CURTIS** and **TROY A. BAIRD**, Department of Biology, University of Central Oklahoma, 100 North University Drive, Edmond, Oklahoma 73034-5209, USA; e-mail: jcurtis5@ucok.edu.

CTENOPHORUS NUCHALIS (Central Netted Ground-dragon). **ENDOPARASITES.** *Ctenophorus nuchalis* occurs in the central and northern coasts of Western Australia, the drier parts of central and northern Australia to central Queensland and western New South Wales; adults measure about 100 mm SVL (Cogger 1996. Reptiles & Amphibians of Australia, 6th ed., Ralph Curtis Publ., Sanibel Island, Florida. 808 pp.). One previous report of helminths exists for *C. nuchalis*; Jones (1995. Aust. J. Zool. 43:141–164) reported larvae assigned to *Abbreviata* (Physalopteridae).The purpose of this note is to report two additional species of Nematoda in *C. nuchalis.*

Coelomic cavities and small and large intestines of 18 *C. nuchalis* (mean SVL = 92 mm ± 12.0 SD, range: 70–110 mm from Western Australia, 28°27'S, 119°05'E [datum: AGD66] elev. ca. 530 m), collected 1966–1967 in the herpetology collection of the Natural History Museum of Los Angeles County (LACM 54225, 54227–28, 54231, 54234, 54236, 54243–44, 54246, 54251, 54254, 54256, 54259, 54268, 54270, 54272, 54274, 54278) were examined for helminths. Stomachs were unavailable for examination; they had been removed during an ecological study that included stomach content analysis (Pianka and Pianka 1976. Copeia 1976:125–142). Nematodes were cleared in a drop of glycerol on a glass slide, cover-slipped and identified as *Maxvachonia brygooi* (infection site: small intestine, large intestine; prevalence: infected lizards/lizards examined × 100 = 39%; mean intensity: mean number of helminths per infected lizard ± SD = 2.0 ± 1.5) and *Parapharyngodon kartana* (infection site: large intestine; prevalence: 6%, mean intensity: 1). Helminths were deposited in the United States National Parasite Collection, Beltsville, Maryland: *Maxvachonia brygooi* USNPC (98266); *Parapharyngodon kartana* USNPC (98267).

Maxvachonia brygooi is known from Australian scincids, agamids and a varanid (Goldberg and Bursey 2000. Trans. Roy. Soc. S. Aust. 124:127–133). *Parapharyngodon kartana* has been found in Australian scincids, agamids and gekkonids (Goldberg and Bursey, *op. cit.*). Infection by *Maxvachonia brygooi* (Cosmocercidae) and *P. kartana* (Oxyuridae) occurs from ingesting eggs (no intermediate host is utilized) (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission. CABI Publishing, Wallingford, U.K. 650 pp.). *Ctenophorus nuchalis* represents a new host record for *Maxvachonia brygooi* and *Parapharyngodon kartana.*

We thank Christine Thacker (LACM) for permission to examine *C. nuchalis* and Dustin Goto (Whittier College) for assistance with dissections.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California, USA (e-mail: sgoldberg@whittier.edu); and **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb@psu.edu).

CTENOSAURA MACROLOPHA (Mainland Spinytail Iguana). **DIET; CLUTCH SIZE.** Adults of members of the genus *Ctenosaura* are typically herbivorous (Durtsche 2000. Oecologia 124:185–195; Durtsche 2004. Physiol. Biochem. Zool. 77:459–470; Köhler 1996. Salamandra 32:153–162), but juveniles may be primarily insectivorous (Durtsche 2000, *op. cit.*; Durtsche 2004, *op. cit.*) and adults are known to take a variety of animal prey (e.g., Arndt 1999. Florida Sci. 62:111–114). Here we report observations on the stomach contents of *C. macrolopha* from Chihuahua, México.

Three *C. macrolopha* (78–89 mm SVL) were collected 5–12 July 2002 from Arroyo El Camuchil, Batopila and road to Satevo (27°1'34.1"N, 107°45'44.5"W, datum: WGS84; elev. 435 m; see Lemos-Espinal et al. 2004. Bull. Chicago Herpetol. Soc. 39:1–7).

TABLE 1. Stomach contents of 3 *Ctenosaura macrolopha* from Chihuahua, México.

Prey Type	Prey Items N =	(%)	Volume cm^3	(%)	Number of Stomachs
Hymenoptera (ants)	28	(58.3)	0.31	(27.2)	3
Isoptera	19	(39.6)	0.76	(66.7)	3
Seed	1	(2.1)	0.07	(6.1)	1

All three animals contained identifiable stomach contents (Table 1). Numerically, ants were the most important prey, but volumetrically termites were most important, although both groups were found in all three stomachs. Presence of a seed in the smallest of the three individuals suggests that *C. macrolopha* may consume fruit. Based on the maximum size of *C. macrolopha* observed near the collection locality (female = 106 mm SVL, male = 120 mm SVL), these individuals likely represent small adults; hence, insectivory might be expected if these animals, like smaller *Ctenosaura* that eat more insects (e.g., Durtsche 2000, *op. cit.*), are still in their interval of rapid growth.

Two of the *C. macrolopha* were females that contained enlarged ovarian follicles. An 87.4 mm SVL animal had 10 enlarged follicles; the other (88.9 mm SVL) had nine enlarged follicles. We are unaware of other reports of clutch size in *C. macrolopha*. However, the clutch sizes we observed for *C. macrolopha* are larger than those reported for *C. defensor* (2–3 eggs; Köhler, *op. cit.*) but similar to the maximum clutch sizes reported for *C. hemilopha* (Goldberg and Beaman 2005. Herpetol. Rev. 36: 317–318).

Specimens are deposited in the Herpetological Collections of the Unidad de Biología, Tecnología y Prototípos (UBIPRO) (JLE9386, 9389, 9392). Collection was conducted under a permit issued to JAL by the Dirección General de Vida Silvestre (DGVS) de la Secretaria del Medio Ambiente y Recursos Naturales.

SMITH**, Department of Biology, Denison University, Granville, Ohio 43023, USA (e-mail: smithg@denison.edu).

DIPLOLAEMUS BIBRONI (NCN). **MOUTH INJURY.** Lizard mouth injuries resulting from foraging activities in the wild are unreported in herpetological literature from South America. In fact, we were unable to find any citation in our survey of the literature related to any wild lizard population. Most external injuries reported for lizards are associated with predation attempts by other animals or result from encounters with conspecifics. Here, we provide the first report of injury resulting from foraging activities in a leiosaurine lizard from central Patagonia, Argentina.

On 25 February 2006, we encountered an adult male *Diplolaemus bibroni* (90.5 mm SVL) basking on an accumulation of small volcanic rocks along Provincial Road 26, 52.3 km W of its intersection with Provincial Road 25, southwest of Pampa de Los Guanacos, Departmento de Sarmiento, Chubut (45°16'43.9"S, 68°43'03.3"W, datum: WGS84; elev. 486 m). After observing its behavior for 10 min, we caught the lizard and held in captivity for 4 weeks. The lizard had an insect thorax jammed in his left lower jaw. Although the insect thorax was fairly large (5 mm long), occupying a significant area of the lizard's mouth (25.7 mm head length), the lizard did not seem to have any obvious limitations in prey capture, mobility or signs of distress, and we did not observe it trying to remove the thorax. The appearance of the wounded area suggested that it was an older injury. Insect part was identified as thorax of a tenebrionid beetle (Family Tenebrionidae, Subfamily Pimeliinae, Tribe Nycteliini, *Nyctella* sp.).

The lizard (LJAMM 3999) was deposited in collection Luciano Javier Avila Mariana Morando (LJAMM) now housed in Centro Nacional Patagónico (CENPAT-CONICET), Puerto Madryn, Argentina.

Submitted by **LUCIANO JAVIER AVILA**, CENPAT-CONICET, Boulevard Almirante Brown s/n, U9120ACV, Puerto Madryn, Chubut, Argentina (e-mail: avila@cenpat.edu.ar); **CRISTIAN HERNAN FULVIO PEREZ**, Los Copihues s/n, Chimpay, Rio Negro, Argentina (e-mail: liolaemu@criba.edu.ar); and **MARIANA MORANDO**, CENPAT-CONICET, Boulevard Almirante Brown s/n, U9120ACV, Puerto Madryn, Chubut, Argentina (e-mail: morando@cenpat.edu.ar).

KENTROPYX LAGARTIJA (NCN**). DIET.** Diet of few species of *Kentropyx* has been studied. *Kentropyx striatus* (Vitt and de Carvalho 1992. Can. J. Zool. 70:1995–2006), *K. pelviceps* and *K. altamazonica* (Vitt et al. 2000. Oecologia. 122:410–420) have all been reported to be insectivorous, but the diet of *K. lagartija* is unstudied. Hence, here we report an observation of predation by a young *K. lagartija* on a *Mabuya* (skink).

On 17 December 2002, we collected a young male *K. lagartija* (4.5 cm SVL) in the Parque Nacional Copo, 3.7 km SE of Puesto Maján (25°51'43.0"S, 62°11'10.1"W, datum: WGS84; elev. 160 m), Santiago del Estero, Argentina. It was found in an open grassy area inside the Chaco Forest. Dissection of this animal revealed a *Mabuya frenata* neonate (2.6 cm SVL) in the stomach.

The *K. lagartija* (MCN 1201) and the *M. frenata* neonate (MCN 1202) were deposited in the herpetological collection of the Museo de Ciencias Naturales of the Universidad Nacional de Salta (MCN).

Submitted by **FEDERICO ARIAS** and **FERNANDO LOBO**, Cátedra de Anatomía Comparada, Facultad de Ciencias Naturales, Universidad Nacional de Salta, Avenida Bolivia 5150, 4400 Salta, Argentina; e-mail: fedejarias@unsa.edu.ar

LEIOSAURUS BELLI (NCN). **PREDATION**. The natural history of *Leiosaurus belli*, a lizard inhabiting the austral Monte and northern Patagonian steppes, is poorly known. In particular, its predators are unreported (Cei 1986. Reptiles del Centro, Centro Oeste y Sur de la Argentina. Monographia IV, Torino, Italy. 527 pp.). Here, we provide the first observation of predation on *L. belli*. On 1 January 1986, A. Gosztonyi obtained a sample of fresh pellets and prey remains from a Burrowing Owl (*Athene cunicularia*)

burrow near Oasis Ranch, 120 km NW Puerto Madryn, Departamento Biedma, Chubut Province, Argentina (42°32'S, 65°40'W, datum: WGS 84; elev. 150 m). Lizards comprised the bulk of vertebrate remains, representing 62% of the individual prey items. Using diagnostic prefrontal bones, we identified 53 individuals of *Leiosaurus belli* from this sample. Variation in prefrontal bone sizes indicated that 28 lizards were juveniles (< 60 mm SVL), 21 were adults 90 mm SVL and 4 were adults > 90 mm SVL. Additionally, eight heads of *L. belli* were found around the burrow entrance, three of which were from adult lizards > 90 mm SVL.

Two aspects of our observation merit comment. First, a high percentage of lizard prey remains represents a pattern unusual for burrowing owl diet in Patagonia, where percentages of lizards taken have been <1.3% (Nabte 2003. Dieta de *Athene cunicularia* [Aves: Strigiformes] en el nordeste de la provincia del Chubut, Argentina. Tesis de licenciatura, Universidad Nacional de la Patagonia San Juan Bosco, Sede Puerto Madryn, Chubut, Argentina. 47 pp.). Second, *L. belli* is a species usually considered to occur at low densities, and that is more active near sunset (Cei, *op. cit.*), when *A. cunicularia* actively hunt (Nabte, *op. cit.*). The high frequency of *L. belli* as lizard prey indicates that either *Athene cunicularia* is a highly efficient hunter or that the density of this lizard, perhaps because of its behavior, has been underestimated.

The pellet sample remains were deposited in the Colección de Material de Egagrópilas y afines "Elio Massoia", Centro Nacional Patagónico CNP-E 86, Puerto Madryn, Chubut, Argentina.

Submitted by **DANIEL UDRIZAR SAUTHIER** (e-mail: dsauthier@cenpat.edu.ar), **NICOLAS FRUTOS** (e-mail: frutos@cenpat.edu.ar), and **LUCIANO JAVIER AVILA** (e-mail: avila@cenpat.edu.ar), CENPAT-CONICET, Boulevard Almirante Brown s/n, U9120ACV, Puerto Madryn, Chubut, Argentina.

LIOLAEMUS PSEUDOANOMALUS (NCN). **REPRODUCTION.** *Liolaemus pseudoanomalus* is an oviparous lizard inhabiting the hot arid landscape of the Monte Phytogeographic Province in northern Argentina (Cabrera and Willink 1980. Biogeografía de América Latina. Washington, D.C. 109 pp.). *Liolaemus pseudoanomalus* has an ambiguous conservation status, defined as a species for which "insufficient knowledge" exists (Lavilla et al. 2000. Categorización de los Anfibios y Reptiles de la República Argentina. Asoc. Herpetol. Arg., Tucumán City. 97 pp.). Data on its biology are sparse. Limited study has been devoted to thermoregulation, sexual dimorphism, time budgets, and space use (Villavicencio et al., *in press*. Amphibia-Reptilia; Villavicencio et al. 2003. Rev. Esp. Herpetol. 17:87–92; Villavicencio et al. 2002. Multequina Latin Amer. J. Nat. Res. 11:51–60; Villavicencio et al. 2003. Nótulas Faunísticas, Segunda Serie 15:1–6; Villavicencio et al. 2003. Bull. Maryland Herpetol. Soc. 42:1–7). Hence, we add the first data addressing *L. pseudoanomalus* reproductive ecology.

We conducted fieldwork in a temporary creek bed near La Laja (31°19'S, 68°41'W, datum: WGS84; elev. 700 m), Departmento de Albardón, San Juan Province, Argentina. Data were collected every 10 days from August 2000 to August 2001 by a random pattern of revisits across the study site. Each animal was measured (SVL) and dissected for gonadal examination. In females, we recorded the number of developing follicles and oviductal eggs, the length and width of oviductal eggs, and the condition of the oviducts. In males, we recorded the width and length of testes to enable calculation of volume based on Dunham (1983. *In* Huey et al. [eds.], Lizard Ecology, pp. 261–280. Harvard Univ. Press, Cambridge, Massachusetts). Testicular volume was natural log-transformed to accommodate its curvilinear function (King 2000. J. Herpetol. 34:148–150). Clutch size was determined from the combined number of developing follicles and eggs in the oviducts. We used the simultaneous presence of developing follicles and enlarged oviducts to suggest that more than one clutch was produced seasonally. The smallest female with vitellogenic follicles or oviductal eggs was used to estimate SVL at maturity. We identified various reproductive states for females: a) non-vitellogenic follicles, b) vitellogenic follicles, c) oviductal eggs and d) post-reproductive (oviducts enlarged).

Males were considered sexually mature if they contained enlarged epididymides. All measurements were obtained to the nearest 0.02 mm with Vernier calipers. Testes of males and fat bodies of both sexes were removed and weighed (to nearest 0.001 g). We used residuals of each of two regressions (testicular volume vs. SVL and fat body mass vs. SVL) to describe male reproductive and fat bodies cycles. This technique retains variation due to extrinsic factors while minimizing the confounding effect of individual variation in SVL (Ramirez-Bautista et al. 1998. J. Herpetol. 32:18–24).

Of 101 captures, 43.6% were sexually mature (29 males and 15 females). Forty females ranged in size from 28 to 68 mm SVL; minimum reproductive size was 59 mm. Female body size was not correlated with clutch size (Spearman: $r_s = 0.50$; $P = 0.20$; N = 8). Clutch size averaged 6.8 (SD = 2.4, range: 2–10, N = 8). We did not observe females with developing follicles and enlarged oviducts simultaneously. Between October and February, we recorded 6 females with vitellogenic follicles. Between November and February, we recorded 4 females with oviductal eggs. Between December and April we recorded 11 females with enlarged

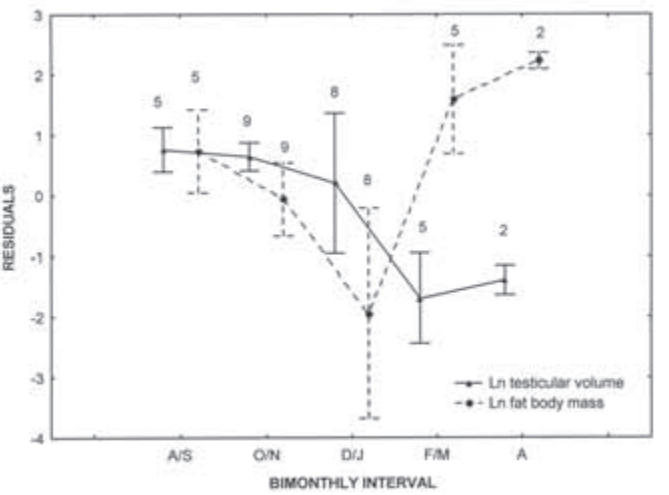

FIG. 1. Bimonthly change in relative testicular volume and fat body mass of the lizards *Liolaemus pseudoanomalus*. Dates are represented as means ± SD. Sample sizes appear above whisker. A/S = August / September; O/N= October / November; D/J = December / January; F/M = February / March and A = April.

oviducts.

Fifty-eight males ranged in size from 22 to 75 mm SVL; minimum reproductive size was 61 mm. Testicular volume was not correlated with body size (Spearman: $r_s = 0.33$; $P = 0.07$; N = 29). Testicular volume varied through the gonadal cycle (ANOVA: $F_{4,24} = 10.75$; $P = 0.0001$; N = 29; Fig. 1).

Seasonal variation in fat body mass (measured as bimonthly samples) was statistically significant (ANOVA: $F_{4.24} = 9.37$; $P = 0.0001$; N = 29; Fig. 1) for males.

Our data suggest that *Liolaemus pseudoanomalus* produces one clutch a year like *L. multimaculatus* (Vega 1999. Ecología de saurios arenícolas de las dunas costeras bonaerenses. Tesis doctoral, inédita, Universidad Nacional de Mar del Plata. 102 pp.) and *L. chacoensis* (Cruz and Ramirez-Pinilla 1996. Rev. Española Herpetol. 10:33–39). Mean clutch size of *L. pseudoanomalus* is larger than *L. darwinii* (mean: 4.9, range: 2–8, N = 40), *L. riojanus* (mean: 4.2, range: 3–6, N = 15) (Blanco et al. 2001, *op. cit.*; Blanco et al. 2003. Reunión de Com. Herpetol. Asoc. Herpetol. Argentina. XVII:31 pp.), *L. koslowskyi* (mean: 4.2, range: 3–9, N = 53) (Aun et al., *op. cit.*); and *L. wiegmanni* (mean: 4.6, range: 4–5, N = 19), *L. multimaculatus* (mean: 4.2, range: 3–7, N = 29), *L. gracilis* (mean: 4.7, range: 4–6, N = 19) (Vega, *op. cit.*) and *L. olongasta* (mean: 3.8, range: 1–8, N = 10) (Cánovas et al., *in press*. Herpetol. Rev.). Our data suggest spring–summer reproductive activity with a late maturing, single annual clutch reproductive strategy (Tinkle 1969. Amer. Nat. 103:501–516).

All specimens (IMCN-UNSJ 4100–4201) were deposited in the Herpetology Collections of Instituto y Museo de Ciencias Naturales of Universidad Nacional de San Juan. I thank M. Hayes for comments and suggestions, and CICITCA- 21E/E633 for financial support.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). **WINTER ACTIVITY.** Reports of winter activity among horned lizards are sparse. One that appeared recently (Wone and Beauchamp 2003. J. Herpetol. 37:679–686) described winter activity of *Phrynosoma mcallii* from California. Although the Texas Horned Lizard, *P. cornutum*, is well studied across its geographic range, the only data close to addressing winter activity are those of Fair and Henke (1999. J. Herpetol. 33:525–517), who described activity prior to hibernation and after emergence in south Texas. Hence, here we report mid-winter activity of *P. cornutum* from west Texas.

Our observations were made in the Dog Canyon area of Big Bend National Park, Brewster County, Texas (29°37'N, 103°09'W, datum: NAD83; elev. 789 m). A small group (N = 3) of *P. cornutum* were individually fitted with PD-2T radio transmitters (Holohil Systems Ltd, Carp, Ontario, Canada) and iButton thermachron temperature dataloggers (Dallas Semiconductor, Sunnyvale, California, USA) to monitor overwinter activities and external temperatures. Additional thermachrons were placed on the ground at each of two reference sites (shade and sun). Dataloggers recorded temperatures every two hours from 1 September 2005 to 16 February 2006. We inferred lizard activity from the temperature datalogger record and verified this by regular observations of the lizards. Lizards were observed twice weekly from 7 August 2005 through 24 April 2006. Each lizard was assigned an alphanumeric identifier of a letter indicating its sex followed by a number. Measurements of each lizard (M1: 96 mm SVL, 73 g; F2000: 111 mm SVL, 99 g; F4000: 107 mm SVL, 93 g) were taken just prior to dormancy.

On 15 September 2005, the male (M1) buried himself 2 cm beneath the ground surface under the cover of a honey mesquite (*Prosopis glandulosa*) and did not emerge from this site until 7 March 2006. The two females buried themselves ca. 2 cm below the ground surface on 24 October 2005, both locations under the cover of *P. glandulosa*. Female F2000 remained underground until emerging on 16 April 2006. Interestingly, female F4000 emerged on 17 December 2005 (58 days after beginning dormancy) and moved to a second location 6 m away where she reburied herself for an additional 104 days until emerging on 2 April 2006. Exposed daytime ground temperatures nearby (~200 m) recorded a high of 29.0°C while the thermachron attached to the lizard's dorsum recorded a high of 29.5°C for 17 December 2005. Both pre- and post-movement refuges were located within one meter of the center of a *P. glandulosa* ca. 2 cm below ground level in sandy soils.

The low temperature recorded for F4000 on the morning of 17 December 2005 prior to its movement was 3.5°C while the thermachrons of two other lizards recorded lows of 7.0°C (M1) and 5.5°C (F2000) that morning. Low temperatures recorded on lizard F4000 10 days before and after movement averaged 5.4°C (range: -1.0–12.5°C) while the other two lizards (M1 and F2000) averaged 6.2ºC (range: 1.0–12.0°C) and 4.4°C (range: -1.5°–10.5ºC), for that time period respectively. An F-test indicated no significant difference in temperature variation recorded on lizard thermachrons before and after F4000 moved.

To our knowledge, this is the first report of mid-winter activity in *P. cornutum*. We believe the winter movement observed may have been a result of the low temperature recorded on the morning of 17 December 2005, but we cannot exclude the possibility of other factors. This type of winter activity may be more common than recognized, and only has come to light with the increasing use of temperature dataloggers and radio telemetry equipment during non-breeding seasons.

Permission for this research was granted to D. J. Leavitt from the National Park Service permit number BIBE-2005-SCI-0052.

PHYLLODACTYLUS TUBERCULOSUS (Yellow-bellied Gecko). **DIET.** Knowledge of *Phyllodactylus tuberculosus* ecology and natural history is sparse. In particular, we have been unable to locate previous reports on its diet. However, reports on the diet of other *Phyllodactylus* from Peru and Iraq suggest that these geckos eat arthropods, especially insects (Weber 1960. Copeia 1960:153–154; Huey 1979. Oecologia 38:249–259). Hence, we provide preliminary data on *P. tuberculosus* diet from Chihuahua, México.

Our observations are based on the stomach contents of 9 *P. tuberculosus* collected from 12–16 July 2000 and from 21–23 July 2003 from two localities: the vicinity of Chínipas (N = 3; 27°22'48.0"N, 108°32'41.1"W, datum: WGS84; elev. 469 m) and the vicinity of Batopilas (N = 6; 27°1'34.1"N, 107°45'44.5"W; elev. 435 m; see Lemos-Espinal et al. 2001. Bull Chicago Herpetol. Soc. 36:201–208; Lemos-Espinal et al. 2004. Bull Chicago Herpetol. Soc. 39:164–168). Of nine individuals, seven contained identifiable stomach contents (Table 1); two had empty stomachs. Numerically, caterpillars were the most important prey, but volumetrically both orthopterans and caterpillars were important. These data agree with other reports of diet in *Phyllodactylus* (Weber, *op. cit.*; Huey, *op. cit.*).

Specimens are deposited in the Herpetological Collections of the Unidad de Biología, Tecnología y Prototípos (UBIPRO) (JLE5917, 5943–5947, 11845–11846, 11869). Collection was conducted under a permit issued to JAL by the Dirección General de Vida Silvestre (DGVS) de la Secretaria del Medio Ambiente y Recursos Naturales.

TABLE 1. Stomach contents of 7 *Phyllodactylus tuberculosus* from Chihuahua, México.

SMITH**, Department of Biology, Denison University, Granville, Ohio 43023, USA (e-mail: smithg@denison.edu); and **JULIO A. LEMOS-ESPINAL**, Laboratorio de Ecología, Tecnología y Prototipos, Facultad de Estudios Superiores Iztacala, UNAM, Apartado Postal 314, Avenida de Los Barrios No. 1, Los Reyes Iztacala, Tlalnepantla, Estado de México, 54090 México (e-mail: lemos@servidor.unam.mx).

PLESTIODON BREVIROSTRIS (Short-nosed Skink). **REPRODUCTION**. *Plestiodon brevirostris*, variable and broadly distributed in Mexico, occurs in high montane pine and pine-oak-dominated terrains. Few data exist on its natural history. Axtell (1960. Copeia 1960:19–26) reported that four females collected in San Antonio de Las Alazanas on 6–7 July had three embryos each. Goldberg (2002. Herpetol. Rev. 33:134) reported that of four females recollected in June, one had two well-developed embryos and three appeared to have already given birth. Goldberg also collected two neonates in June: a 23 mm SVL animal on 19 June, and a 21 mm SVL individual on 27 June. However, he did not indicate the locality of origin of either the female or the neonates. Hence, we provide reproductive data on *P. brevirostis* from different points across its geographic range.

Each of the three females gave birth in captivity shortly after the date of collection. The first (MZFC 18774; 62 mm SVL, 50.4 mm tail [partly regenerated], 4.74 g) was collected in Pablillo, Nuevo León (24°34'53.0"N, 99°57'56.2"W, datum: WGS84; elev. 2330 m), in a forest dominated by *Pinus teocote* and *Quercus* spp. on 1 July 2005. On 13 July, this female gave birth to three live offspring, and the next day a fourth. After parturition, the female weighted 2.74 g. The SVL, tail length, and mass (mean ± SE) of the four neonates were 26.25 ± 0.12 mm, 25.25 ± 012 mm, 0.303 ± 001 g, respectively. The second female (MZFC 18779; 65 mm SVL, 37 mm tail [partly regenerated], post-parturition mass = 3.24 g) was collected ca. 14 miles E of San Antonio de las Alazanas, Coahuila, near of type locality of *P. b. pineus* (25°13'1.2"N, 100°23'17.9"W, elev. 2919 m) in forest dominated by *Pinus cembroides* on the same date as the previous female. On 14 July, this female gave birth to four neonates (mean ± SE: 26.87 ± 0.34 mm SVL, 24.75 ± 0.13 tail, 0.291 ± 005 g). The third female (MZFC 19135, 59 mm SVL, 132.2 mm tail, post-parturition mass = 3.5 g) was collected in Los Lirios, Coahuila (25°22'32.5"N, 100°30'38.9"W; elev. 2429 m) in a *Pinus cembroides-Cupressus* sp. forest on 2 July 2005. This female birthed two neonates (25.0 ± 0.12 mm SVL; 25.0 ± 0.15 mm tail) on 10 July 2005.

We also collected four neonate-sized lizards. Two (MZFC 18767–18768, both 25.0 mm SVL, 25.0 mm tail) near Marmolejo, Tamaulipas in the Sierra de San Carlos (24°37'19.8"N, 99°01'55.0"W; elev. 596 m) in a *Pinus pseudostrubus-Quercus canbyi* forest on 30 June 2005 at the type locality of *P. b. dicei*. The other two lizards were collected in Pablillo (MZFC 18770, 25.0 mm SVL, 25.0 mm tail), and in Los Lirios (MZFC 18783, 26.5 mm SVL, 27.5 mm tail) on 1 and 2 July of 2005, respectively. Locality data are as indicated previously. Our data suggest that both *P. b. dicei* and *P. b. pineus* give birth from late June to mid-July.

We also collected one presumptively neonate-sized lizard on 15 March 2006. This lizard (MZFC 19134, 27.0 mm SVL; 14 mm tail [broken]) was collected 4.8 km N of Mitla, Oaxaca, near the type locality of *P. b. brevirostris* (16°59'03.1"N, 96°20'05.3"W; elev. 2453 m). Assuming neonates at this latitude are birthed at a similar size, this suggests that the southern populations of *P. brevirostris* (i.e., *P. b. brevirostris*) are born about three months before offspring from populations in northeast Mexico (i.e., *P. b. dicei* and *P. b. pineus*).

The specimens were deposited in the herpetological collection of Museo de Zoología de la Facultad de Ciencias, in the Universidad Nacional Autónoma de México.

Submitted by **MANUEL FERIA ORTIZ**, Museo de Zoología, Facultad de Estudios Superiores Zaragoza, Universidad Nacional Autónoma de México, Batalla de 5 de mayo s/n, Col. Ejército de Oriente, México 09230, D.F., México; **URI OMAR GARCIA**

VAZQUEZ, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, A.P. 70-399, México, D.F. 04510, México; and **JOSE LUIS AGUILAR LOPEZ**, Laboratorio de Herpetología, Escuela de Biología, Benemérita Universidad Autónoma de Puebla, C.P. 72570, Puebla, México.

PLESTIODON FASCIATUS (Five-lined Skink). **PREY**. At 1519 h on 11 June 2006, a mature male Five-lined Skink (67.2 mm SVL, 7.15 g) was observed stalking prey in the Clemson University Experimental Forest near the Issaqueena Dam (34°44'08.8"N, 82°51'46.1"W, datum: WGS 84; elev. 191 m) in South Carolina. The skink seized the potential prey item, pinned it to the ground and I captured it by hand within 5 sec of it seizing the item. The prey was identified as a Carolina Scorpion, *Vaejovis carolinianus* (0.37 g, 4.33 mm carapace length). The scorpion was held in the lizard's mouth by the cephalothorax with one pedipalp in the mouth and one extending from the right side. The scorpion was motionless and made no effort to sting or pinch. This method of seizing and holding scorpions, a potentially dangerous prey item, differs from that used by the Spotted Whiptail, *Cnemodophorus gularis* (O'Connell and Formanowicz 1998. J. Herpetol. 32:75–79), which repeatedly bit, shook, and released the bark scorpion, *Centruroides vittatus*, in laboratory studies. Arachnids have been reported to comprise a large percentage of the diet of some populations of *P. fasciatus* (Fitch 1954. Univ. Kansas Publ. Mus. Nat. Hist. 8:1–156). However, to our knowledge, this represents the first published record of predation on a scorpion by *P. fasciatus*.

Submitted by **CHARLES M. WATSON** and **DANIEL FORMANOWICZ**, Department of Biology, The University of Texas at Arlington, Arlington, Texas 76019, USA (e-mail: cwatson@uta.edu)

PODARCIS SICULA CAMPESTRIS (Italian Wall Lizard). **PREDATION**. Few accounts have mentioned predation on the wall lizards introduced to Long Island, New York. Long Island lacks native lizards and hence may lack predators that typically take them. Gossweiler (1975. Copeia 1975:584–585) suggested that cats, dogs, sea gulls, and "one snake" might prey on the introduced Long Island lizards; Burke and Ner (2005. Northeast Nat. 12:349–360) listed Northern Mockingbirds (*Mimus polyglottos*), Blue Jays (*Cyanocitta cristata*), and American Crows (*Corvus brachyrhynchos*) as potential predators. To date, the only predators documented to prey upon *P. sicula campestris* are non-native house cats (Burke and Ner, *op. cit.*), and spiders (species not identified) and mantids (probably *Tenodera aridifolia*) on hatchling lizards (Burke and Deichsel, *in press*. Herpetol. Conserv.).

I observed a single predation event while studying a population of *P. sicula campestris* at the Carle Place train station in Carle Place, New York (40°44'56"N, 73°36'19"W, datum: WGS84; elev. 30 m). The station, dominated by low growing exotic shrubs (e.g., *Artemisia vulgaris*) and herbaceous annuals and perennials (e.g., *Centaurea* sp.), lacks substantial shade. On 12 June 2006 at 1155 h, a *Corvus brachyrhynchos* was seen with an adult *P. sicula campestris* in its beak sitting on a pile of railroad ties ca. 2 m from the tracks. The capture was not witnessed. The crow was first observed holding the lizard by the torso in its beak, then dropped the lizard at its feet and picked at it several times before flying away with the lizard in its beak as a passenger train approached the station. Until the crow flew off, the lizard's tail had remained intact, implying capture by the head or torso given the lizard's ability to autotomize its tail when grabbed.

I also observed a predation attempt by an Eastern Garter Snake, *Thamnophis sirtalis sirtalis*. *Thamnophis s. sirtalis* are abundant at the Carle Place train station and can often be seen basking during morning hours in close proximity to *P. sicula campestris* in open clearings close to nearby vegetation (pers. obs.). On 17 June 2006 at 1112 h, a *T. s. sirtalis* (ca. 65 cm) was observed moving through low growing vegetation behind the westbound platform. An adult female *P. sicula campestris* was seen basking in a relaxed position (front limbs extended back against the body) in a nearby clearing ca. 1 m from the patch of vegetation partly concealing the snake. The snake slowly entered the clearing and came within 1 m of the lizard before the lizard became alarmed and quickly retreated to a nearby patch of vegetation ca. 2 m away. The snake chased the lizard into the vegetation, where the lizard rapidly ascended an *A. vulgaris* plant. After the failed capture attempt, the snake moved deeper into the vegetation, where it was not seen again. The *P. sicula campestris* descended after 4 mins and resumed basking on the vegetation edge.

No documented reports of Eastern Garter Snakes preying upon introduced wall lizards exist. Moreover, instances of *Thamnophis s. sirtalis* preying on any lizard are rare (Hamilton 1951. Am. Midl. Nat. 46:385–390; Carpenter 1952. Ecol. Monogr. 22:235–258). Hence, despite my observation of attempted predation, *Thamnophis s. sirtalis* might not be expected to be a frequent predator of the introduced lizards on Long Island.

Submitted by **ROBERT W. MENDYK**, 68 12th Street, Carle Place, New York 11514, USA; e-mail: odatriad@yahoo.com.

SCELOPORUS CYANOGENYS (Blue Spiny Lizard). **PREDATION.** There are few reports concerning the natural history of *Sceloporus cyanogenys*. Current knowledge addresses reproduction (Kennedy 1960. Southwest. Nat. 5:44–45), general behavior (Greenberg 1977. J. Herpetol. 11:177–195), taxonomy and distribution (Wiens and Reeder 1997. Herpetol. Monogr. 11:1–101), and mite infestations (García-de la Peña et al. 2005. Bull. Chicago Herpetol. Soc. 40:52–53). Recently, Castañeda et al. (2006. Herpetol. Rev. 37:227) added the Southwestern Rat Snake (*Pantherophis emoryi*) to its predator set. Here, we add *Trimorphodon tau tau* to that predator set.

At 2300 h on 6 May 2006 (air temperature 28°C) during a vertebrate inventory in the municipalities of Dr. Gonzalez, Higueras, and Cerralvo in the Sierra Picachos at a place called Rancho Fraile, Nuevo Leon, México (25°55'20"N, 99°46'12"W, datum: NAD27; elev. 435 m), we observed an adult male *S. cyanogenys* (109.mm SVL, 134 mm tail, 46.4 g) being consumed by a female *T. tau tau* (880 mm TL, 180.8 g including prey). Our observation occurred on a human-built brick structure (2 m × 1.5 m) covered with an unidentified vine. When first observed, the snake had seized the lizard. The feeding sequence took ca. 20 min. Local vegetation consists of a submontane matorral association of *Prosopis glandulosa* and *Hellieta parvifolia.* The snake was released following examination.

Information on the natural history of *Trimorphodon tau tau* is sparse (McDiarmid and Scott 1987. Los Angeles Co. Mus. Nat. Hist. 179:1–44; Scott and McDiarmid 1984. Cat. Amer. Amphib. Rept. 354.1). McDiarmid and Scott (*op. cit*.) provided the only dietary data for the species, indicating that it consumes frogs and lizards and may eat small mammals. They specify the genera *Cnemidophorus* and *Sceloporus* as lizard prey, but specific species are not mentioned. Because related species of *Trimorphodon* are reported to take these genera (Bogert 1939. Publ. Univ. California Los Angeles, Biol. Sci. 1:177–236), their appearance as prey items may be a generic-level pattern. This observation is the first record of *S. cyanogenys* as prey for *T. tau tau*.

Submitted by **JORGE A. CONTRERAS-LOZANO, DAVID LAZCANO,** and **ARMANDO JESUS CONTRERAS-BALDERAS,** Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado, Postal - 513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México; e-mail: (DL) dvlazcano@hotmail.com.

SCELOPORUS OCCIDENTALIS (Western Fence Lizard). **PREY**. The Argentine Ant (*Linepithema humile*) is a common invasive in California that competitively displaces native ants (Holway 1999. Ecology 80:238–251) and negatively affects some reptile species. Coast Horned Lizards (*Phrynosoma coronatum*) typcially do not eat Argentine Ants (Montanucci 1989. Herpetologica 45:208–216; Suarez et al. 2000. Ecol. Appl. 10:711–725) or experience negative growth rates in invaded communities when forced to consume them and other non-ant arthropods (Suarez and Case 2002. Ecol. Appl. 12:291–298). As a consequence, *P. coronatum* appears to avoid areas where Argentine Ants are abundant (Fisher et al. 2002. Conserv. Biol. 16:205–215). Argentine Ants also appear to negatively affect Orange-throated Whiptails (*Aspidoscelis hyperythra beldingi*) by displacing their natural prey items (Jennings and Hayes 1994. Amphibian and Reptile Species of Special Concern in California. California Dept. Fish Game, Inland Fisheries Division. Contract No. 8023. 260 pp.). Information on Argentine Ant consumption by other reptiles is lacking. Here, we report consumption of Argentine Ants by a *Sceloporus occidentalis* using unusual methods of prey capture.

At 1500 h on 12 June 2006, we observed a pair of *S. occidentalis* at the Santa Barbara Zoological Gardens, Santa Barbara Co., California (34°25'15"N, 119°39'58"W, datum: WGS84; elev. 9 m) moving out from underneath a metal tub and basking on gravel adjacent to a blacktop road. The male (ca. 8 cm SVL) moved into a path of Argentine Ants and stopped. Ants began to crawl on him intermittently. When an ant would crawl on his head, he would quickly consume it without displaying rejection behaviors (e.g., regurgitating, spitting out the prey). This unique method of prey capture was observed on five occasions over a period of ca. 15 min. The female (ca. 6 cm SVL) was not observed eating the ants. To our knowledge, this is the first report of Argentine Ant predation by *S. occidentalis* and potentially indicates flexibility in Western Fence Lizard diet. As Argentine Ants appear to be generally rejected by ant-consuming California reptiles, their consumption by *S. occidentalis* deserves further investigation, particularly for its potential effects on fence lizard body size and fitness.

We thank Michael Caterino (Santa Barbara Natural History Museum) for identifying five Argentine Ants, which were deposited in the SBNHM. We also thank Marc Hayes (Washington Department of Fish and Wildlife), Sam Sweet (University of California at Santa Barbara), Andrew Suarez (University of Illinois at Urbana-Champaign), and Estelle Sandhaus (Santa Barbara Zoological Gardens) for providing assistance in preparing this manuscript through valuable discussions of and information about Argentine Ants.

Submitted by **C. DREW FOSTER** (e-mail: cucdf4@hotmail.com), **PATRICK MARTIN**, and **SHAWN STACKPOOLE**, Santa Barbara Zoological Gardens, Animal Care Department, 500 Niños Drive, Santa Barbara, California 93103, USA.

SPHENOMORPHUS CHERRIEI (Striped Litter Skink, Chirbala Lisa). **ENDOPARASITES.** *Sphenomorphus cherriei*, a small diurnal litter-dwelling skink reaching 178 mm total length, occurs from central Veracruz, México on the Atlantic versant and Costa Rica on the Pacific slope to extreme western Panama (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents Between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.). To our knowledge, no endoparasites are known from *S. cherriei.* The purpose of this note is to report one species of Digenea and three species of Nematoda from *S. cherriei.*

Coelomic cavities and stomachs and small and large intestines of 10 *S. cherriei* (mean SVL = 49 mm ± 3.8 SD, range: 43–55 mm) from Costa Rica collected between 10°04'N to 10°46'N and 83°22'W and 84°70'W (datum: WGS84) during 1959, 1960, and 1963 from the herpetology collection of the Natural History Museum of Los Angeles County (LACM 161180–161189) were examined for helminths. Digeneans were regressively stained in hematoxylin, mounted in Canada balsam, studied as whole mounts and identified as *Mesocoelium monas* (infection site: small intestine; prevalence: infected lizards/lizards examined × 100 = 10%; mean intensity: mean number of helminths per infected lizard ± SD [where appropriate] = 11). Nematodes were cleared in a drop of glycerol on a glass slide, cover-slipped, and identified as *Oswaldocruzia nicaraguensis* (infection site: stomach, small intestine; prevalence 30%; mean intensity 1.3 ± 0.60), *Physaloptera* sp. (infection site: stomach; prevalence 10%; mean intensity 7) and acuariid larvae (infection site: stomach wall; prevalence 10%; mean intensity 6). Helminths were deposited in the United States National Parasite Collection, Beltsville, Maryland: *Mesocoelium monas* USNPC (98269), *Oswaldocruzia nicaraguensis* USNPC (98270), *Physaloptera* sp. USNPC (98271), acuariid larvae USNPC (98272).

Mesocoelium monas has a wide distribution among amphibians and reptiles in the Neotropics, Oceania, and the Orient (Goldberg et al. 2005. Comp. Parasitol. 72:88–101). Cercariae emerge from the sporocyst to encyst in the viscera of a molluscan host or occasionally leave the host to encyst on vegetation; infection occurs upon ingestion of an infected snail or vegetation containing cysts (Prudhoe and Bray 1982. Platyhelminth Parasites of the Amphibia. British Museum, Oxford University Press, Oxford, United Kingdom. 217 pp.). *Oswaldocruzia nicaraguensis* was described from *Ameiva festiva* from Nicaragua (Bursey et al. 2006. J. Parasitol.

92:350–352). *Sphenomorphus cherriei* is the second species to harbor this nematode. Infection is direct (no intermediate host) (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission, 2nd ed. CABI Publishing Oxon, United Kingdom. 650 pp.). Larvae of *Physaloptera* sp. (but not adults) are commonly found in amphibians and reptiles (Goldberg et al. 1993. Bull. South. California Acad. Sci. 92:43–51). *Physaloptera retusa* is the common species found in lizards of the Americas (Bursey et al. 2005. Comp. Parasitol. 72:50–68); but males are necessary to assign species. Physalopteridae utilize insect intermediate hosts (Anderson, *op. cit.*). Species of the Acuariidae are normally parasites of birds and utilize arthropod intermediate hosts (Anderson, *op. cit.*). Adults are not known from reptiles which likely serve as transport (paratenic) hosts. *Norops limifrons* from Costa Rica has also been reported to harbor acuariid larvae (Bursey and Goldberg 2003. J. Parasitol. 89:573–576).

Sphenomorphus cherriei represents a new host record for *Mesocoelium monas*, *Oswaldocruzia nicaraguensis*, *Physaloptera* sp., and acuariid larvae. Costa Rica is a new locality record for *O. nicaraguensis.*

We thank Christine Thacker (LACM) for permission to examine *S. cherriei*. Specimens are from the CRE collections donated to LACM by Jay M. Savage. Dustin Goto (Whittier College) assisted with dissections.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); and **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb@psu.edu).

TUPINAMBIS MERIANAE (Tiú, Teiú, Tegu, or Teju). **DIET**. *Tupinambis merianae*, a large, diurnal teiid, is broadly distributed from the Amazon River in Brazil southward to Argentina, Paraguay, and Uruguay (Colli et al. 1998. Herpetologica 54:477–492). Although the species is known to eat terrestrial arthropods, small vertebrates, and quantities of fruit (*op. cit.*), and therefore might also contribute to seed dispersal (Castro and Galetti 2004. Pap. Avul. Zool. 44:91–97), the range of its dietary habits, and hence its trophic ecology, are poorly known. Here, I present the stomach contents analysis of an adult *T. merianae* from southern Brazil that augments data on its diet.

The *T. merianae* examined, a large (27 cm SVL) adult male, was killed on Brazilian Highway PR 160 on 13 February 2000, adjacent to Klabin Ecological Park, in the municipality of Telêmaco Borba, in the state of Paraná (24°20'S, 50°35'W, datum: SAD69; elev. 715 m). Examination of the entire digestive tract contents of this individual revealed 14 different taxa, two plants and 12 animals: 6 gabiroba fruits (*Campomanesia xanthocarpa*); 8 false-coerana fruits (*Vassobia breviflora*); 2 beetles (Coleoptera: Cerambycidae: Prioninae); 2 crickets (Orthoptera: Gryllacrididae); 2 katydids (Orthoptera: Tettigoniidae), and 3 grasshoppers (Orthoptera: Acrididae); 1 (Orthoptera: Proscopiidae); 1 cicada (Hemiptera: Cicadidae); 5 caterpillars: 1 of which was a sphingid (Lepidoptera: Sphingidae: Sphinginae), and 4 saturniids (Lepidoptera: Saturniidae: Hemileucinae); 1 spider (Arachnida: Lycosidae); 1 millipede (Diplopoda); parts of an eggshell of the cowbird (*Molothrus bonariensis*); and the skull of a bat (Chiroptera: Vespertilionidae).

The cowbird egg might have come from a ground-nesting host, such as *Zonotrichia capensis*. Lack of other bones might indicate that the bat skull came from an already dead animal. This wide range of food items might indicate that the *T. merianae* is opportunistic, which might help explain its broad distribution.

Thanks to José Ricardo M. Mermudes, Margareth Sekiama, Marcelo Duarte, Mauro Pichorim, and Vlamir Rocha for their help in identification of various items; to Sergio A. Filipaki for his help in the field; to Klabin Paraná for logistic support; to James Joseph Roper and Marc P. Hayes for assistance with the text.

Submitted by **REGINALDO ASSÊNCIO MACHADO**, Center of Biology and Nature Science, Federal University of Acre, Campus Floresta, Cruzeiro do Sul, State of Acre, Brazil; e-mail: anurans@uol.com.br.

UMA EXSUL (Coahuila Fringe-toed Lizard). **SWIMMING.** The six recognized species in the genus *Uma* are sand habitat specialists well known for their ability to literally "swim" in sand (Cornett

FIG. 1. An adult *Uma exsul* swimming across a temporary pool (top) following heavy precipitation at the Bilbao Dunes, Coahuila, Mexico (bottom).

1983. Pacific Discovery 36:2–10; Pough et al. 1978. Copeia 1978:81–86; Jayne and Daggy 2000. J. Exp. Biol. 203:1241–1242). The fact that these highly xeric-adapted terrestrial lizards can also swim in the water remains unreported. Here, we report observations of the swimming ability of *Uma exsul*, a protected species endemic to the Chihuahua Desert (SEMARNAP 2000. Diario Oficial de la Federación [16 Octubre], México, D.F., México).

During October 2002 and July 2003, we observed two different *U. exsul* swim in the well-known dunes at Bilbao in the Municipality of Viesca, Coahuila, México (25°26'33.64"N, 102°53'33.19"W, datum: NAD27; elev. 1093 m) (Fig. 1). On each occasion, we observed an adult (70 and 72 mm SVL, respectively) swim across pools 8–20 cm deep. The pools were the result of heavy precipitation during those years (Comisión Nacional del Agua, Estación Meteorológica: Emiliano Zapata, Coahuila, 2004).

The lizards swam over a distance of about 10 m and 15 m, respectively. On the first occasion, the lizard was first observed at one end of the pool and swam across; no predator or conspecific was observed that might have precipitated the swim. During the July 2003 observation, the lizard was initially observed swimming in the center of the pool. The swimming movement made a serpentine pattern that was especially evident in the tail; this animal would stop periodically to float and to change direction.

Swimming behavior would allow *Uma exsul* to move between dunes or escape a predator during intervals when water fills interdune depressions.

Submitted by **JOSÉ LUIS ESTRADA-RODRÍGUEZ** and **SANDRA V. LEYVA PACHECO**, Centro de Estudios Ecológicos – Escuela Superior de Biología, Universidad Juárez del Estado de Durango, Av. Universidad S/N. Fracc. Filadelfia, Gómez Palacio Durango, México (e-mail: josefo7@hotmail.com).

URACENTRON FLAVICEPS (Thornytail Iguana). **ENDOPARASITES.** *Uracentron flaviceps* is a medium-sized (100 mm SVL adults) tropidurid lizard found in western Amazonia, Brazil, Colombia, Ecuador, and Peru (Avila-Pires 1995. Lizards of Brazilian Amazonia [Reptilia: Squamata]. Zoologische Verhandelingen Nationaal Natuurhistorisch Museum, Leiden, Netherlands. 706 pp.). To our knowledge, no reports of parasites from *U. flaviceps* exist. The purpose of this note is to report two species of nematodes, *Physaloptera retusa* and *Physalopteroides venancioi* from *U. flaviceps*.

Five *U. flaviceps* females (mean SVL = 86 mm ± 1.5 SD, range: 84–88 mm) from Moropon, on Río Nanay (3°43'S, 73°14'W, datum: WGS84; elev. 100 m), Department Loreto, Peru, collected 13 September 1973 were borrowed from the Texas Cooperative Wildlife Collections (TCWC), Texas A&M University, College Station, Texas (TCWC 44562–63, 44566, 44568–69). The esophagus, stomach, small and large intestines were opened and separately examined for helminths under a dissecting microscope. The body cavity was also examined for helminths. Two species of nematodes, *Physaloptera retusa* (one adult female from the stomach of TCWC 44569) and *Physalopteroides venancioi* (one adult female from the stomach of TCWC 44563) were found. Nematodes were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as: *Physaloptera retusa* (USNPC 99001) and *Physalopteroides venancioi* (USNPC 99002).

Physaloptera retusa is widely distributed in lizards and two bufonid species in the New World (Bursey et al. 2005. Comp. Parasitol. 72:50–68). Larvae occur in insects (Schell 1952. J. Parasitol. 38:462–472; Lincoln and Anderson 1975. Can J. Zool. 53:385–390). Lizards presumably become infected by eating insects containing larvae. *Physalopteroides venancioi* is known from South American anurans and lizards (Bursey et al., *op. cit.)*. Life cycles of species of *Physalopteroides* are unstudied, but like other members of the Physalopteridae, insects are probable intermediate hosts (Anderson 2000. Nematode Parasites of Vertebrates. Their Development and Transmission. CABI Publishing, Oxon, United Kingdom. 650 pp.). Both *P. retusa* and *P. venancioi* have previously been reported in other lizard species from Peru (Bursey et al., *op. cit.*). *Physaloptera retusa* and *P. venancioi* in *U. flaviceps* are new host records.

We thank Toby Hibbitts (Department of Wildlife and Fisheries, Texas A&M University) for permission to examine specimens and Sarah Goldsberry (Whittier College) for assistance with dissections.

SERPENTES

AGKISTRODON BILINEATUS (Cantil). **REPRODUCTION**. *Agkistrodon bilineatus* ranges along the Pacific Coast and foothills from southern Sonora, Mexico, southward through México into Guatemala, Belize, Honduras, and Nicaragua (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York. pp. 262–265). Currently, three subspecies are recognized within the *A. bilineatus* complex. The northern subspecies, *A. b. bilineatus*, occurs along the Pacific Coast of Mexico, Guatemala, and El Salvador, and in the Rio Grijalva Valley of Chiapas, Mexico (Campbell and Lamar, *op. cit*.). Little published information exists regarding the biology of the northern subspecies, *A. b. bilineatus.* Furthermore, the cantils as a group are under extreme pressure as vast amounts of habitat are being rapidly converted to agricultural lands (Parkinson et al. 2000. Mol. Ecol. 9:411–420). Species-specific surveys with the Tropical Deciduous Forest (TDF) of southern Sonora have yielded few additional specimens of *A. bilineatus*.

At approximately 0900 h on 10 July 2004, an adult female *A. b. bilineatus* (ca. 533 mm TL) was killed by a farmer on the Las Cabras Ranch, Alamos, Sonora. The ranch lies within the foothills of the Sierra Madre Occidental within the TDF zone. The snake was discovered in a pile of decomposing leaves in a mango-avocado orchard. It was collected of by one of us (SM) and immediately frozen. We opened the snake to check for stomach contents, and discovered three neonates in the early stages of development. To our knowledge this represents the first litter for the species in the state of Sonora.

Submitted by **ERIC A. DUGAN**, Department of Earth and Biological Sciences, Loma Linda University, Loma Linda, California

CONIOPHANES IMPERIALIS (Black-striped Snake). **DIET**. *Coniophanes imperialis* is a small, terrestrial snake that can be active day or night. *Coniophanes* spp. are known to have a broad diet that includes insects, salamanders, frogs, frog eggs, lizards, snakes, reptile eggs, bird eggs, insects, and earthworms (Köhler 2003. Reptiles of Central America. Herpeton Verlag, Offenbach, Germany. 367 pp.; Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. University of Chicago Press, Chicago, Illinois. 934 pp.), although *C. imperialis* has only been reported to consume lizards, frogs, and insects (Campbell 1998. Amphibians and Reptiles of Northern Guatemala, the Yucatan, and Belize, University of Oklahoma Press, Norman. 380 pp.). We report two prey items for *C. imperialis* on the island of Cayo Cochino Pequeño in the Cayos Cochinos Archipelago (Islas de la Bahia, Honduras).

On 27 May 2006 at 1700 h we captured a small female (177 mm SVL, 29 mm tail, 4.0 g) *C. imperialis* with an obvious prey bulge, crawling through the leaf litter. We forced the snake to regurgitate and identified the food item as a single lizard egg suspected to be *Norops lemurinus*, based on size and shape of the egg and that *N. lemurinus* is the most common polychrotid lizard on the island. Although *Coniophanes* spp. are known to feed on reptile eggs (Köhler, *op. cit.*) our observation represents the first report of *C. imperialis* preying on lizard eggs (Campbell, *op. cit.*).

On 21 June 2006 at 1600 h we observed a large male (245 mm SVL, 115 mm tail, 11.0 g) *C. imperialis* in the leaf litter that contained a very large food item. After capturing the snake and forcing it to regurgitate we identified the partially digested prey item as an adult male (65 mm SVL, 9 mm tail, 6.0 g) *N. lemurinus*. The lizard represented 54.5% of the snake's mass and a 43.1% of its length. *Coniophanes imperialis* is known to consume lizards, but our observation represents the first report of *N. lemurinus* in the diet of *C. imperialis*. Our observation is also the largest reported meal by mass or length for *C. imperialis* (Alvarez de Toro 1960. Los Reptiles de Chiapas. Inst. Zool. Estado, Tuxtla Gutierrez, Chiapas, 204 pp.), although *C. fissidens* was reported to consume an *Eleutherodactylus rugulosus* that weighed 76.4% of snake mass (Seib 1985. Biotropica 17:57–64).

We thank the Honduran Coral Reef Foundation and Operation Wallacea for supporting our research in the Cayos Cochinos.

CONOPSIS NASUS (Large-nosed Earth Snake). **PREDATION.** On 3 October 2005, while conducting a road transect along Road No. 68 in the state of Aguascalientes in central Mexico, we found a DOR male Coachwhip (*Masticophis flagellum*) (SVL 920 mm, TL 200 mm). Close examination of the carcass (possibly killed the day before) revealed two partially digested *Conopsis nasus* (SVL 110 mm each, sexes undetermined) protruding from the gut. To our knowledge this is the first record of predation of *M. flagellum* on *C. nasus*.

CROTALUS HORRIDUS (Timber Rattlesnake). **BEHAVIOR.** On 7 March 1998 we observed an adult *Crotalus horridus* at a communal hibernaculum in Scioto County, Ohio, USA. The snake alerted us to its presence by rattling, and dried mud was present on its tail. Skies were partly cloudy with occasional periods of sunlight and a light breeze. Ambient temperature was 14°C and substrate temperature was 18°C. Earliest emergence date is a key component of the seasonal cycle of this species (Brown 1993. Biology, Status, and Management of the Timber Rattlesnake [*Crotalus horridus*]: A Guide for Conservation. SSAR Herpetol. Circ. No. 22, 78 pp.). Published accounts of the seasonal cycle of *C. horridus* in Ohio note observations from May to September (Conant 1938. Amer. Midl. Nat. 20:1–200). To our knowledge, this is the earliest emergence date for *C. horridus* at this latitude (Martin 1992. *In* J. A. Campbell and E. D. Brodie Jr. [eds.], Biology of the Pitvipers, pp. 259–278. Selva Press, Tyler, Texas).

CROTALUS LEPIDUS LEPIDUS (Mottled Rock Rattlesnake). **DIET**. The diet of *Crotalus lepidus* recently was reviewed by Holycross et al. (2002. J. Herpetol. 36:589–597), and relatively little information exists on mammals consumed by rock rattlesnakes under natural conditions. Mammals consumed by this species in the wild include shrew, mouse, *Dipodomys* spp., *Chaetodipus* spp., *Perognathus* spp., *Peromyscus* spp., and *Sigmodon* spp. (Holycross et al., *op. cit.*).

On 23 March 2005 I observed and photographed an adult *C. l. lepidus* consuming an adult White-ankled Mouse (*Peromyscus pectoralis*) at 1350 m elev. in Carlsbad Caverns National Park, Guadalupe Mountains, Eddy Co., New Mexico, USA (Arizona State University, ASU HP-00054). This event was observed below the stone amphitheater on the paved switchback trail leading into the large natural entrance of Carlsbad Cavern. At about 2230 h (Mountain Standard Time), I found the *C. l. lepidus* swallowing the *P. pectoralis* head-first with back legs and white ankles of the mouse still visible, which facilitated the specific identification (see

Fig. 63 in Geluso and Geluso 2004. Mammals of Carlsbad Caverns National Park, New Mexico. Bull. Univ. Nebraska State Mus. 17:1–180). My sighting represents the first documentation of a known species of mammal being consumed by *C. lepidus* under natural conditions. Information on the natural history of this subspecies is important because it is listed as endangered by the New Mexico Department of Game and Fish (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. University of New Mexico Press, Albuquerque).

Submitted by **KEITH GELUSO**, Department of Biology, University of Nebraska at Kearney, Kearney, Nebraska 68849, USA; e-mail: gelusok1@unk.edu.

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). **BEHAVIOR**. Observations of the directional movements of experimentally displaced *Crotalus atrox* (Landreth 1973. Copeia 1973:26–31) and the straight-line paths of migratory *C. viridis viridis* between seasonal habitats (Duvall et al. 1985. Nat. Geogr. Res. 1:80–111) have led to the suggestion that rattlesnakes use celestial cues (e.g., the sun) for orientation. However, the use of other cues for orientation and navigation by rattlesnakes can not be ruled out based on limited experimental evidence. This observation of the homing ability of a naturally displaced prairie rattlesnake suggests that the species possesses not only a compass sense but also a map sense (Type III orientation; Griffin 1952. Biol. Rev. 27:359–400), providing knowledge of their location in relation to a destination. I employed radio telemetry to track the migrations of 18 non-gravid female Prairie Rattlesnakes, *Crotalus v. viridis*, from two dens near Medicine Hat, Alberta, Canada in 2005. One radio tagged rattlesnake was tracked across the South Saskatchewan River to its north side on 16 May (Fig. 1). The radio tagged rattlesnake remained on the north side of the river until 17 September and all recorded locations during this period were within approximately 560 m of the den of origin. On 18 September the rattlesnake crossed the river and was located on its south side ca. 2000 m east of its last known location. The river flows from west to east and it is assumed that the snake drifted downstream when crossing. Prior to this displacement the den was ca. 453 m from the snake's location on a true bearing of 103°. After displacement the den was ca. 1621 m away on a bearing of 246°. On the day following the crossing the snake moved 55 m from her previous location on a bearing of 333°. On the third and fourth day, four positions were recorded as the rattlesnake moved 1610 m back to the den. The route taken by the snake approximated a straight line with a mean bearing of 243.3° + 4.2°.

In this instance type II orientation can be discounted because the rattlesnake did not continue to orient as if it had not been displaced (Lawson 1994. Copeia 1994:263–274). Lohmann et al. (2004. Nature 428:909–910) stated, "Migratory animals capable of navigating to a specific destination, and of compensating for an artificial displacement into unfamiliar territory, are thought to have a compass for maintaining their direction of travel and a map sense that enables them to know their location relative to their destination." If we assume that Prairie Rattlesnakes are capable of using the sun as an effective compass it would allow the displaced rattlesnake to maintain a heading, but this would not account for the rattlesnake's apparent knowledge of its location relative to the den. Map sense in other taxa (e.g., turtles and birds) is thought to be based on the use of visual (Avens and Lohmann 2003. J. Exp. Biol. 206:4317–4325) or solar cues (Akesson et al. 2005. Current Biol. 15:1591–1597) combined with magnetic cues. Among snakes, chemosensory cues could also be used in combination with other cues for navigation during migration (Brown and Parker 1976. Copeia 1976:225–242; Fitch 1960. Univ. Kansas. Mus. Nat. Hist. Misc. Publ. 13:85–288; Lawson 1989. Musk-Ox 37:110–115). This observation of a naturally displaced Prairie Rattlesnake suggests

FIG. 1. Seasonal movements of a radio-tagged *Crotalus viridis viridis* displaced while crossing the South Saskatchewan River.

that this animal was capable of type III orientation. The advanced navigational abilities of Prairie Rattlesnakes might be based on the use of multiple sensory cues but further research is required to identify the role and importance of individual cues.

DENDRELAPHIS PICTUS (Gmelin's Bronzeback). **DISPERSAL.** A juvenile *Dendrelaphis pictus* was found onboard a traditional fishing boat used for the transportation of tourists between Sape on the eastcoast of Sumbawa and Komodo Island, Indonesia. The boat embarked us as well as food (e.g., vegetables obtained in Sape), on 25 August 1998, and we were transported to the harbor off Kampong Komodo where we stayed overnight. The ship was never attached to a bridge at Komodo Island but remained anchored in a bay. The snake was discovered onboard the ship late afternoon the next day (26 August 1998). It seems impossible that it could have entered the ship from Komodo Island because no cargo was loaded there. More likely it was loaded with vegetables obtained in Sape on Sumbawa. The ship was used for this type of tourist transportation and had not visited other areas "for a long time," as the skipper informed me, so the snake probably originate from this area. All crew members, as well as the tourists onboard reacted negatively on the presence of the snake and killed it, suggesting the snake was not brought onboard intentionally. This observation is interesting because it illustrates the ease with which snakes can be accidentally transported by human activities.

The snake is deposited in the collection of the Natural History Museum, Göteborg, Sweden, under the number GNM Re.ex. 6587 and the identification was verified by Göran Nilson at this museum.

DRYMARCHON CORAIS COUPERI (Eastern Indigo Snake). **FEEDING BEHAVIOR.** *Drymarchon corais couperi* is a dietary generalist that feeds on a wide range of vertebrate prey species including fish, frogs, toads, lizards, snakes (including venomous species), small turtles, birds, and small mammals (Moler 1992. Rare and Endangered Biota of Florida, Vol III: Amphibians and Reptiles. University of Florida Press, Gainesville. 291 pp.). *Drymarchon c. couperi* is a robust species that typically overpowers its prey using its strong jaws while pinning the prey item to the substrate with a body coil, usually swallowing its prey alive (Moler, *op. cit.*). Herein we report, not only a novel incident of carrion feeding in this species, but also a novel feeding behavior for Serpentes.

On 18 March 2001 at approximately 1330 h an adult *D. corais couperi* (ca. 2 m total length) was observed in the field at Pier 4, Playalinda Beach (Canaveral National Seashore, Brevard Co., Florida, USA) feeding on the head of a decapitated shark (species undetermined). Skies were overcast, ambient temperature was ca. 20°C, and a strong wind was blowing from the east. The feeding event occurred on top of a sand dune vegetated with sea oats (*Uniola paniculata*). Upon approaching the site, a Black Vulture (*Coragyps atratus*) flew off prior to observing the presence of the *D. corais couperi*. Feeding behavior consisted of the snake thrusting its head into the exposed neck musculature of the shark head and biting the exposed tissue. The snake would then twist its head and upper body laterally in attempt to tear the meat away. This behavior was observed for approximately three minutes, during which time it was photographed. The snake then ceased the biting behavior but continued to investigate the lateral surfaces of the shark head that had the skin intact, using its rostrum and lower jaw to push on it three more times. This behavior appeared to be associated with the snake's interest in locating additional feeding opportunities along the shark head. At this time the presence of small pieces of tissue derived from the neck musculature of the shark could be seen surrounding the upper and lower labial scales. The snake then abruptly left the carcass and crawled away into the dune grasses, appearing undisturbed. The amount of shark musculature actually ingested (if any) could not be determined as peristaltic contractions of the esophagus and neck region associated with swallowing could not be discerned.

A radio-telemetry study of over 80 *Drymarchon c. couperi* has been conducted from 1998 through 2005 in similar habitat at the Kennedy Space Center, Brevard Co., Florida, during which time carrion feeding was never observed (R. Bolt, pers. comm.). Observation of a snake attempting to tear pieces of flesh from a disarticulated carcass has not been previously reported.

Submitted by **AUDREY SMITH**, 211 Bailey Avenue, Titusville, Florida 32796, USA; and **FRED ANTONIO**, Department of Herpetology, Central Florida Zoological Park, P.O. Box 470309, Lake Monroe, Florida 32747, USA.

ELAPHE GUTTATA (Corn Snake). **PREY/PREDATOR WEIGHT RATIO.** To our knowledge, published accounts where prey mass has been equivalent to, or exceeded that of the predator have involved viperids (Greene 1983. Amer. Zool. 23:431–44; Lindey and Sorrell 2004. Herpetol. Rev. 35: 272–273; Mulcahy et al. 2003. Herpetol. Rev. 34:64) and boids (Weaver 2005. Herpetol. Rev. 36:189). Among the largest prey/predator weight ratios for colubrids are those reported by Lind and Welsh (1990. J. Herpetol. 24:104–106), who documented weight ratios for the genus *Thamnophis* as high as 0.88, and Tucker (2000. Herpetol. Rev. 31:106–107), who reported prey/predator weight ratios between 0.20 and 0.58 in four species of neonatal colubrid snakes. Hamilton et al. (1956. Ecology 37:519–526) described one instance of an *E. guttata* with a juvenile *Sigmodon hispidus* in its stomach that exceeded the weight of the snake, but did not provide the mass of predator or prey. Here we describe an observation of an *E. guttata* with an equivalent prey/predator weight ratio.

On 30 March 2006, one of us (TGJ) collected a neonate female *E. guttata* (369 mm SVL, 10 g) with a large bolus in its stomach. The snake was located in the southwestern corner of the Camp Shelby Training Site, Perry County, Mississippi, USA. I palpated a 10 g *Peromyscus* sp. from the snake's stomach, resulting in a prey/predator weight ratio of 1.00. An unsuccessful attempt was made to re-feed the prey item to the snake which was released at

the point of capture the following day.

We thank Geoffrey G. Sorrell and Matthew G. Hinderliter for their comments.

Submitted by **THOMAS G. JACKSON, JR.** (e-mail: jacksontg@hotmail.com), and **JAMES R. LEE** (e-mail: jlee@tnc.org), The Nature Conservancy, CSTS-ENV Building 6678, Camp Shelby, Mississippi 39407, USA.

LEPTODEIRA ANNULATA (Banded Cat-eyed Snake). **DIET**. The anuran *Leptodactylus mystaceus* (Leptodactylidae) is distributed in the Amazon Basin from its southern limit in Brazil to Paraguay, Bolivia, Peru, Ecuador, Colombia, Venezuela, and the Guianas (Frost 2002. Amphibian Species of the World: An Online Reference V3.0). During a visual encounter survey on 07 November 2004, at 2125 h, an adult *L. mystaceus* (INPA-H 15713; 47 mm SVL; 8.7 g), was found being ingested by the snake *Leptodeira annulata* (Colubridae; INPA-H 12778; 601 mm SVL; 53 g), in a dry forest stream in the Brazilian Parque Nacional do Pico da Neblina (São Gabriel da Cachoeira municipality, Amazonas state). The snake was swallowing the frog head-first. From the time we first encountered it, the snake took an additional seven minutes to finish swallowing the frog. The new record reinforces assertions that *L. mystaceus* prey extensively on anurans (Vitt 1996. Herpetol. Nat. Hist. 4:69–76).

VOGT**, Instituto Nacional de Pesquisas da Amazônia, Coleção de Anfíbios e Répteis, Coleções Zoológicas, INPA – Campus II. Av. André Araújo, 2936, C.P. 428, CEP 69.083-000 Manaus, Amazonas, Brazil.

LEPTODEIRA ANNULATA (Banded Cat-eyed Snake). **MATING**. *Leptodeira annulata* occurs from Mexico to Argentina (Peters and Donoso-Barros 1986. Catalogue of Neotropical Squamata. Part I, Snakes. Revised ed. Smithsonian Institution, Washington, D.C. 347 pp.). The ecology of *L. annulata* has been studied (Vitt 1996. Herpetol. Nat. Hist. 4:69–76), but little is known regarding its mating behavior.

On 08 Jun 2005, we found one female (577 mm SVL, 177 mm tail length, 36 g) and three male (514, 533, and 473 mm SVL; 188, 187, and 176 mm tail length; 24, 23, and 19 g, respectively) *L. annulata* in a pitfall trap at Floresta Nacional de Carajás, eastern Brazilian Amazônia (06°02'S, 50°15'W). The snakes were forming a breeding ball and were releasing a strong odor. When handled, males discharged fetid cloacal secretions and the female expelled a large amount of sperm from the vent. This observation suggests that, although this species is primarily arboreal, mate searching occurs in the ground, perhaps because tracking pheromone trails in the discontinuous arboreal substratum is difficult.

This observation was supported by Compahia Vale do Rio Doce.

LEPTODEIRA ANNULATA (Banded Cat-eyed Snake)**. SIZE, REPRODUCTION, AND PREY.** The colubrid snake *Leptodeira annulata* has a wide distribution in the Neotropics, ranging from Mexico to Argentina (Peters and Orejas-Miranda 1986. Catalogue of the Neotropical Squamata, Part I – Snakes. Smithsonian Institution Press, Washington D.C. 347 pp.). Most of the published information on the ecology of *L. annulata* in South America originated from Amazonian populations (Fitch 1970. Misc. Publ. Mus. Nat. Hist. Univ. Kansas 52:1–247; Duellman 1978. Misc. Publ. Mus. Nat. Hist. Univ. Kansas 65:1–352; Henderson et al. 1979. Milwaukee Publ. Mus. Contr. Biol. Geol. 22:1–11; Vitt 1996. Herpetol. Nat. Hist. 4:69–76; Martins and Oliveira 1998. Herpetol. Nat. Hist. 6:78–150). Data are currently lacking for this species in the Atlantic Forest of eastern Brazil. In this note we report data on body size, reproductive traits, and stomach contents of an individual from an Atlantic Forest locality in southeastern Brazil.

On 28 September 2004 at 2105 h during a herpetofaunal survey at the Paraíso Ecological Station (22°29'S, 42°55'W; Guapimirim Municipality, Rio de Janeiro State, Brazil) two of us (DV and CCS) found a female *L. annulata* (718 mm SVL; 920 mm TL; 87 g) at the margin of a stream. The snake had a distinct mid-body bulge, indicating that it had eaten recently. Upon dissection, we found five eggs in the oviducts, with a mean length of 23.4 ± 1.7 mm (range 21.0–25.7 mm) and a mean width of 11.1 ± 1.7 mm (range 9.6–14.0 mm). The snake's stomach contained a partially digested *Bufo crucifer* (70 mm SVL) which had been swallowed head-first. The snake and its stomach contents were deposited at the Museu Nacional, Rio de Janeiro (MNRJ 12232).

Total length of MNRJ 12232 was larger than the maximum total lengths (between 760–870 mm) reported for *L. annulata* (Duellman 1958. Bull. Amer. Mus. Nat. Hist. 114:1–152; Duellman 1978, *op. cit.*; Fitch 1981. Misc. Publ. Mus. Nat. Hist. Univ. Kansas 70:1–72; Martins and Oliveira, *op. cit.*) and its SVL was greater than the maximum SVL (659 mm) of 59 Amazonian specimens examined by Vitt (*op. cit.*; total lengths not given). On the other hand, Savage (2002. The Amphibians and Reptiles of Costa Rica. University of Chicago Press, Chicago, Illinois. 934 pp.) reported a maximum total length of 1038 mm for this species in Costa Rica, which exceeds the size of MNRJ 12232. Nevertheless, the specimen reported here represents, to our knowledge, the largest size on record for *L. annulata* in South America.

Clutch size of this individual (five eggs) is within the ranges reported by Fitch (1970, *op. cit.*) for Amazonian Peru (2–7 eggs; mean = 4.0) and Vitt (*op. cit.*) for Amazonian Brazil and Ecuador (3–6 eggs; mean = 4.7). The eggs, on the other hand, were large compared to those reported for females of Amazonian populations: Vitt (*op. cit.*) reported an average length of 19.0 mm (range 13.5–22.4 mm) and an average width of 7.4 mm (range 5.3–10.2 mm) for 25 eggs taken from five females and Martins and Oliveira (*op. cit.*) recorded lengths of 17–18 mm and widths of 7–8 mm for six eggs taken from one female. It would be interesting to examine more *L. annulata* specimens from the Atlantic Rainforest domain to verify whether they usually lay larger eggs than their Amazo-

nian conspecifics, as suggested by the present data.

Prey reported for *L. annulata* at various localities consist almost exclusively of anuran amphibians, mainly hylids and leptodactylids (Duellman 1958, *op. cit.*; 1978, *op. cit.*; Vitt, *op. cit.*; Martins and Oliveira, *op. cit.*). Vitt (*op. cit.*) recorded one bufonid (*Bufo granulosus*) and Duellman (1958, *op. cit.*) reported three species of *Bufo* (*B. marinus*, *B. typhonius*, and *B. valliceps*) and a few indeterminate *Bufo* specimens from stomachs of *L. annulata*. The present note reports another species of *Bufo* as prey of *L. annulata*, which suggests that predation on such animals by this snake might not be infrequent. Thus, the toxic secretions from the parotoid glands of *Bufo* spp. do not seem to be an efficient deterrent from predation by *L. annulata*, which might not be affected by the toxin to any significant degree. The present data also indicate that *L. annulata* does not stop feeding during pregnancy.

We thank A. Pissinatti for allowing the authors to work at the Paraíso Ecological Station, José P. Pombal Jr. for identifying the toad, and the Center for the Conservation of Biodiversity (CCB) for logistic support.

LEPTODEIRA ANNULATA (Banded Cat-eyed Snake). **PREY**. *Leptodeira annulata* is an arboreal and nocturnal colubrid that ranges from México through Central America and the Amazon basin into northern Argentina. Often it is found in trees and bushes near water and feeds primarily on anurans (Duellman 1958. Bull. Amer. Mus. Nat. Hist. 114:1–152; Savage 2002. The Amphibians and Reptiles of Costa Rica. The University of Chicago Press, Chicago, Illinois. 954 pp.).

On 12 March 2004 at 2140 h we observed an *Osteocephalus taurinus* (Anura) sitting on a rock ca. 50 cm above a small tributary to the Rio Chumilla (between Shapaja and Chazuta in the Tarapoto region of Peru, ca. 500 m elev.). Over a distance of ca. 5 m, a *L. annulata* (ca. 1 m TL) approached the frog from amidst overhanging branches. The frog leapt from its rock and was seized by the snake in mid-air. The snake ingested the seemingly alive, but paralyzed frog (hindlimbs first), while hanging head-down from its original perch over a period of ca. 30 minutes. To the best of our knowledge, this is the first documentation of *L. annulata* predation on *O. taurinus*.

LIOPHIS REGINAE (Reticulated Snake). **DIET.** Throughout large parts of the Neotropics, peccaries (Tayassuidae, *Pecari tajacu* and *Tayassu pecari*) create and maintain wallows in the forest understory. These pools provide year-round breeding habitat for amphibians that opportunistically breed in pools. For several years, one of us (HB) has worked at the Cocha Cashu Biological Station within the Manu National Park (11°52'S, 71°21'W), Peru to test whether peccaries function as ecosystem engineers by creating new habitats (wallows) that may be colonized by other species. On 23 March 2005 while monitoring the breeding activities of the leptodactylid frog *Edalorhina perezi* at peccary wallows, we noticed a juvenile (186 mm SVL) *Liophis reginae* inside a terrestrial *E. perezi* foam nest. As the snake left the foam nest it was collected and preserved in 70% ethanol. Upon dissection, we found six *E. perezi* tadpoles in its stomach. This is the first record of *L. reginae* preying upon *E. perezi* tadpoles inside a foam nest. Depredation of frog eggs and larvae by snakes is well documented in the Neotropics, and several snake taxa may be considered anuran specialists. Few predators, however, have been documented feeding within the foam nests of leptodactylid frogs.

The snake (TUMZ 8051), the ingested tadpoles and voucher specimens (TUMZ 8052) from the foam nest are permanently stored at the Museum of Zoology at Towson University, Department of Biological Sciences.

MASTICOPHIS FLAGELLUM FLAGELLUM (Eastern Coachwhip). **GROWTH AND MOVEMENT.** Little is known regarding growth rates of *Masticophis flagellum* and limited data have been generated regarding their movement (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 668 pp.). Herein we report on a PIT-tagged male *M. flagellum* that was captured three times over a 23-month time period in Baker Co., Georgia, USA. In May 2003, the individual measured 1605 mm SVL, 2078 mm TL, and 940 g. Reliable measurements were not taken during June 2004, when the snake was captured a second time. In April 2005, the same individual was recaptured and measured 1622 mm SVL, 2089 mm TL, and 951 g. The first and second capture locations were 1469 m apart (straight line distance) and separated by Ichawaynochaway Creek (a major tributary of the Flint River) while the second and third locations were 291 m apart (straight line distance) for a minimum cumulative movement of 1760 m. *Masticophis flagellum* are known to travel considerable distances (ca. 1 km; Secor 1995. Herpetol. Monogr. 9:169–186) but to our knowledge, movements on this scale have not been recorded. In addition, movement across aquatic habitats such as creeks or rivers does not appear to have been previously documented in this species.

NERODIA ERYTHROGASTER FLAVIGASTER (Yellow-bellied Watersnake). **DIET**. *Nerodia erythrogaster* is a prey generalist with a diet consisting of crayfish, a variety of fish, salamander, anurans and their larvae. The majority of prey consumed by this semi-aquatic snake are amphibians including the potentially toxic toads of the genus *Bufo* (Gibbons and Dorcas 2004. North American Watersnakes: A Natural History. Univ. Oklahoma Press, Norman, Oklahoma. 438 pp.). Previously reported bufonid species have included *B. americanus*, *B. houstonensis*, *B. terrestris*, *B. valliceps*, and *B. woodhouseii*. There has been discrepancy in the literature about the validity of *Bufo velatus* as a species. Some researchers regard it as an intergrade between species in the *B. woodhouseii* complex (Conant and Collins 1998. Reptiles and Amphibians: Eastern and Central North America. Houghton Mifflin Co., New York. 616 pp.; Dixon 2000. Amphibians and Reptiles of Texas. Texas A & M University Press, College Station, Texas. 421 pp.). Herein, *B. velatus* is considered a species according to recent literature and systematic analysis (Dixon 2000, *op. cit.*; B. Fontenot, pers. comm.). No previous records are known of *N. erythrogaster* consuming *B. woodhouseii* within the currently understood range of *B. velatus*; thus this report is the first documentation of the East Texas Toad, *B. velatus*, as a prey item of *N. erythrogaster*.

On 2 May 2004 a *N. erythrogaster* (763 mm SVL, 310 g) was collected from under an artificial cover item at the Old Sabine Bottom Wildlife Management Area (OSBWMA) Smith County, Texas, USA (32°35.853'N, 95°20.369'W). A gravid female *B. velatus* (43.1 g) was palpated from the specimen.

NERODIA ERYTHROGASTER FLAVIGASTER (Yellow-bellied Watersnake). **ANTI-PREDATORY BEHAVIOR**. Tail breakage is an anti-predatory strategy employed by several species of snake (Mendelson 1992. Herpetologica 48:448–445; Fitch 2003. Herpetol. Rev. 34:212–213). When a snake is captured by the tail it may roll or rapidly undulate to facilitate breakage. The remaining tail fraction creates little movement and the snake is provided an opportunity for escape. This behavior, however, potentially has detrimental effects on locomotion, courtship, and defensive behavior (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. University of Oklahoma Press, Norman. 332 pp.; Chapple et al. 2004. J. Herpetol. 38:137–140). This note is the first documentation of tail breakage by *Nerodia erythrogaster*.

On 9 April 2005, a female *N. erythrogaster* (720 mm SVL, 226.3 g) was found under a piece of tin at the Old Sabine Bottom Wildlife Management Area, Smith County, Texas, USA (32°35.945'N 095°20.638'W). The snake was seized by the tail as it attempted to flee. Very soon after restraint, the snake rotated its body and the tail broke off in my hand. The intact tail length was 179 mm and the disconnected tail fraction was 73 mm. Based upon length, approximately 29% of the tail was lost.

Submitted by **PAUL M. HAMPTON**, Department of Biology, University of Texas at Tyler, 3900 University Blvd, Tyler, Texas 75799, USA.

NERODIA FASCIATA CONFLUENS (Broad-banded Watersnake). **DIET**. *Nerodia fasciata* is primarily a piscivorous snake (Mushinsky and Hebrard 1977. Herpetologica 33:162–166). A wide variety of amphibians, however, have also been documented as food items (Gibbons and Dorcas 2004. North American Watersnakes: A Natural History. University of Oklahoma Press, Norman, Oklahoma. 438 pp.). Five species of salamander, representing four families, have previously been reported as prey. Here I report the first published record of the family Ambystomatidae in the diet of *Nerodia fasciata*.

On 29 March 2005, a *N. fasciata* (163 mm SVL, 6 g) was found under a piece of corrugated tin at the Old Sabine Bottom Wildlife Management Area (OSBWMA) Smith County, Texas, USA (32°35.853'N, 95°20.369'W). The individual readily regurgitated a prey item identified as an *Ambystoma texanum* metamorph (0.7 g) approximately half-digested. The nearby pool was sampled for *A. texanum* larvae. Of three captured larvae, the mean SVL was 34.7 ± 5.8 mm and the mean mass was 1.93 ± 0.8 g. The OSBWMA is a bottomland floodplain that experiences occasional flooding. The floods create ephemeral pools that contain pulsed resources such as fish. However, droughts and dams up-river of the site have decreased the frequency and intensity of natural floods and fish are no longer common in the vernal pools. *Ambystoma texanum*, on the other hand, are quite numerous in this floodplain and are abundant prey items for many semi-aquatic snakes species.

Submitted by **PAUL M. HAMPTON**, Department of Biology, University of Texas at Tyler, 3900 University Blvd, Tyler, Texas 75799, USA.

PHILODRYAS OLFERSII (NCN)**. NATURAL HISTORY.** *Philodryas olfersii* is found in western Brazil and eastern Peru through Bolivia and Paraguay to Uruguay and Argentina. Despite its wide distribution, information regarding the ecology of the species is scarce and focused in small portions of the species' distribution (e.g., northeastern Brazil). In Pantanal, the species was found in rocky areas, deciduous and semideciduous forest and urban environments. Here, we present data from oviposition in captivity and activity in rocky areas near Corumbá, Mato Grosso do Sul, Brazil. On 26 November 1998, five eggs with a mean length of 49.5 ± 4.9 mm (44.1–57.6 mm), mean width of 17.3 ± 1.2 mm (16.3–19.2 mm), and mean volume of 7800 ± 1297 mm^3 were found in Laboratório de Zoologia of Campus de Corumbá. After 73 days, four hatchlings with an average mass of 7.1 ± 1.1 g (5.8–8.5 g) emerged. Unfortunately, we did not measure the hatchlings. One month later (day 19) in the terrarium of the same female nine eggs were found with mean length 33.4 ± 2.7 mm (29.3–37.9 mm), mean width 17.3 ± 2.1 mm (14.8–21.5 mm), and mean volume 5263 ± 1336 mm^3. In this case only three eggs hatched (after 39 days), with a mean mass of 3.8 ± 0.4 g, mean SVL of 214.0 ± 10.8 mm, and mean tail length of 93.7 ± 4.0 mm. One hatchling died within 3 minutes of hatching. The specimens have been deposited in Coleção Zoológica de Referência do Campus de Corumbá (CEUCH 167, 191–195).

We captured five *P. olfersii* in rocky areas from June 2003 to March 2004. We found two individuals basking in bromeliads at 0700 h and 1324 h, one on the ground below bushes at 1525 h, and two were found foraging at 1340 h and 1450 h. Foraging behavior

consisted of constant movement in search for prey in bushes ca. 3 m high. One individual (CEUCH 044, SVL 946 mm) had a juvenile *Bufo schneideri* (TL 33.2 mm) in its stomach. Our observations suggest that *P. olfersii* is an active forager, uses foliage for foraging and basking, appears to produce more than one clutch/year, and oviposits in the early rainy season, unlike populations in the Caatinga of northeastern Brazil (Vitt 1980. Pap. Av. Zool. 34:87–98).

PITUOPHIS CATENIFER SAYI (Bullsnake). **NESTING**. On 20 June 2005, while monitoring turtle activity at a drift fence north of Gimlet Lake on the Crescent Lake National Wildlife Refuge in Garden County, Nebraska, USA (see Iverson 1991. Herpetologica 47:371–393), we encountered an obviously gravid (palpable eggs, freshly ecdysed) female Bullsnake (1110 mm snout–vent length; 118 mm tail length; ca. 475 g body mass). Because of her condition and direction of movement (from low meadow to upland sandhills), we presumed that she was moving to oviposit, and force-fed her a transmitter (model LF1-STL-RS, LL Electronics, Urbana, Illinois) coated in wax (total weight 9 g) and released her. Over the next five days she spent the nights underground in an abandoned pocket gopher (*Geomys bursarius*) burrow complex (diameter of all nocturnal locations ca. 1 m). During the day she ventured up to 29 m (17 m minimum) from that complex, and when not actively moving, was found coiled in the partial shade of one of many yuccas (*Yucca glauca*) in the area. At 0545 h on 25 June she was underground in the gopher burrow, but at 0940 h she was obviously spent (298 g body mass, including transmitter) after having crossed the drift fence on her way toward the meadow. We assumed that she oviposited the previous night. She was captured at 1015 h after moving ca. 104 m directly toward Gimlet Lake (total distance from the burrow complex to the cattails fringing the lake's shoreline, ca. 200 m).

On 26 June at 0900 h we excavated the gopher burrow complex and located the snake's clutch of 9 eggs (mean length 44.4 mm; mean width 27.7 mm) in a single cemented cluster (total mass 176.8 g) at the end of a shallow branch off the main gopher burrow below where it had been located the day before. Depth from the soil surface to the top egg was 263 mm, and to the bottom of the lowest egg, 312 mm. We also found the shed skin of a much larger *P. catenifer* in another branch of the same burrow complex, but no other evidence of any other snakes or eggs. The nest site was on a southwest-facing (237 degrees), 14 degree slope in a sparsely vegetated area of mid-grass prairie dominated by Needle and Thread Grass (*Stipa comata*), bluestems (*Andropogon* sp.), Switchgrass (*Panicum virgatum*), yucca, and introduced cheat grass (*Bromus* sp.). Early on 27 June she defecated the transmitter and was released in the meadow.

Although nest sites of the Pinesnake (*Pituophis melanoleucus*) have been well described (Burger and Zappalorti 1991. J. Herpetol. 25:152–160), only anecdotal reports are available for *P. catenifer.* In western Oregon communal nests of Pacific Gophersnakes (*P. c. catenifer*) were found in "cavities" in a talus slope, with one specifically found at a depth of 30 cm in an inactive rodent burrow (Brodie et al. 1969. Herpetologica 25:223–227). Similarly, in British Columbia at least two female Great Basin Gophersnakes *(P. c. deserticola*) nested communally in a rodent burrow (Shewchuk 1996. M.S. thesis, Univ. of Victoria), and in northern Utah at least four females nested singly or communally (sometimes with *Masticophis taeniatus*) in abandoned rodent burrows at depths of 34–42 cm (Parker and Brown 1980. Milwaukee Publ. Mus. Publ. Biol. Geol. 7:1–104). These data suggest that *P. melanoleucus* excavates its nest burrows, whereas *P. catenifer* uses natural cavities or burrows for oviposition; however, further data are needed for both species to determine the universality of this pattern.

PITUOPHIS MELANOLEUCUS LODINGI (Black Pinesnake) **CARRION FEEDING.** Members of the genus *Pituophis* are known to take a wide variety of prey items, including small mammals, birds and their eggs, lizards, snakes and their eggs, and insects (Ernst and Barbour 1989. Snakes of Eastern North America. George Mason University Press, Fairfax, Virginia. 282 pp.; Rodríguez-Robles 1998. Copeia 1998:463–466; Rodríguez-Robles 2002. Biol. J. Linn. Soc. 77:165–183). However, information pertaining to the diet and the prey items selected by the Black Pinesnake (*Pituophis melanoleucus lodingi*) are limited (e.g., Cliburn 1962. Herpetologica 18:34–37; Rudolph et al. 2002. Herpetol. Nat. Hist. 9:57–62). Herein I report an instance of carrion feeding by *P. melanoleucus lodingi*.

On 24 June 2005 at 1203 h, a female *P. melanoleucus lodingi* (121 cm SVL, 615 g), implanted with a radio transmitter (Holohil, SI-2T), was located as part of an ongoing radio-telemetry investigation into the movement patterns and general life history of *P. melanoleucus lodingi* on the Camp Shelby Training Site, Perry County, Mississippi, USA. The snake was observed basking 5 m from the entrance to an underground refugium (stump hole), and appeared to have recently fed as indicated by a large bolus in its stomach. Upon palpating the snake a young *Sciurus niger* was regurgitated. The squirrel was fairly decomposed and completely covered in maggots (still alive). When the snake was released it quickly retreated to the nearby stump hole, and the squirrel was placed in front of the refugia's entrance. The next day the snake was rediscovered in the exact location it had been observed the previous day and had presumably re-ingested the squirrel since it was nowhere to be found, and the snake was observed with a similarly sized bolus in its stomach. The presence of maggots on the prey item suggests the squirrel had died prior to being consumed, and the fact that the maggots were still alive implies the snake had recently eaten the animal. The frequency and propensity to scavenge and the relative contribution that carrion represents in the diet of the Black Pinesnake is unknown. However, carrion probably plays an important supplementary role, as is the case with a number of other snake species (See DeVault and Krochmal 2002. Herpetologica 58:429–436).

Submitted by **JAMES R. LEE**, The Nature Conservancy, Camp Shelby Field Office, CSTS-ENV Building 6678, Camp Shelby, Mississippi 39407, USA; e-mail: jlee@tnc.org.

PITUOPHIS MELANOLEUCUS LODINGI (Black Pinesnake). **SEXUAL BEHAVIOR.** *Pituophis melanoleucus lodingi* is a large, secretive colubrid whose range is limited to the Gulf Coastal Plain of Louisiana, Mississippi, and Alabama. Seasonal timing of sexual behavior (e.g., courtship, coitus) for this subspecies has not been reported, although detailed studies on the reproductive biology and reports of courtship exist for *P. m. melanoleucus* and *P. m. mugitus* (Ashton and Ashton 1981. Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Windward Publ. Inc., Miami, Florida. 176 pp.; Zappalorti et al. 1983. Bull. Chicago Herpetol. Soc. 18:57–72; Burger and Zappalorti 1986. Copeia 1986:116–121; Gerald and Holmes 2004. Herpetol. Rev. 35:180). The literature indicates that courtship takes place during late spring (the month of May, in both Tennessee [Gerald and Holmes, *op. cit.*] and New Jersey [Zappalorti et al., *op. cit.*] populations); although Goldberg and Parker (1975. Herpetologica 31:317–322) suggested that breeding throughout the year is possible. Here I report the first observation of copulatory behavior in a pair of *P. m. lodingi* from Mississippi, and possibly the latest known seasonal instance of such behavior for *P. melanoleucus*.

On 28 September 2005, at 1035 h, I observed a pair of *P. m. lodingi* copulating in the southwestern corner of the Camp Shelby Training Site, in Perry County, Mississippi, USA. Both individuals (male: 149.5 cm SVL, 1001 g; female: 121.2 cm SVL, 615 g) carried intraperitoneally implanted radio-transmitters weighing less than 5% of body mass. The pair was loosely coiled on the ground with the male's entire body positioned on top of the female's with the exception of the tail, which was extended along the side of her body in such a manner as to allow for copulation. Ambient air temperature was 33.2°C during the time of the observation and no precipitation occurred within the previous 24 h. The snakes remained together in the same area for 3 days following the initial observation, but were located below ground, in a rotted-out pine root system, during each visit. On the fourth day both snakes moved to different locations ca. 300 m apart.

Submitted by **JAMES R. LEE**, The Nature Conservancy, Camp Shelby Field Office, CSTS-ENV Building 6678, Camp Shelby, Mississippi 39407, USA; e-mail: jlee@tnc.org.

PYTHON MOLURUS BIVITTATUS (Burmese Python). **NESTING**. Although *Python molurus bivittatus* is native to Southeast Asia, both adult and juvenile specimens have been collected in Everglades National Park, Florida, USA, since the mid 1990s (Meshaka et al. 2000. Florida Sci. 63:84–102). Breeding of free-living *P. m. bivittatus* has not been confirmed anywhere in Florida. Here we document the first nest outside of captive breeding efforts in the United States.

On 25 January 2006 a female *P. m. bivittatus* was collected within Everglades National Park. On 8 February 2006 she was released with two VHF radio transmitters implanted subcutaneously as part of a study on movements and habitat use. On 17 May 2006 we located the female to remove her from the field and found her coiled around eggs (Everglades National Park Museum photograph, EVER 41050).

The nest (25.36°N, 80.68°W, elev. 0.5 m) was located in an overgrown debris pile (approximately a 20 m semicircle) comprised mainly of vines, small forbs and shrubs, other vegetation, cut logs, PVC pipe, barbed wire, poster-board, planks, cardboard, pieces of a filing cabinet, and other materials. The nest was located under a piece of metal that was under a nodule of the root system of the tallest tree (a Brazilian Pepper, *Schinus terebinthifolius*) in the debris pile. The eggs were clustered on a circle of decomposed organic matter ca. 80 cm in diameter. The nest had 46 eggs (42 fertile, 2 infertile, and 2 opened at the nest and not measured). Mean egg length (N = 44) was 91.8 mm (SD = 6.5), mean egg width was 62.7 mm (SD = 4.0), mean egg mass was 189.1 g (SD = 37.2). Mean embryo length (N = 24) was 90.0 mm (SD = 6.8).

To date, there are scant data of *P. m. bivittatus* nest structure or material, although pythons are known to nest in mammal burrows, hollow logs, cavities under rocks, and around plant roots (Minton and Minton 1973. Giant Reptiles. C. Scribner's Sons, New York. 345 pp.).

Submitted by **RAY W. SNOW**, South Florida Natural Resources Center, Everglades National Park, 40001 State Road 9336, Homestead, Florida 33034, USA (e-mail: skip_snow@nps.gov); **VALERIE M. JOHNSON** (e-mail: johnsonv@ufl.edu), **MATTHEW L. BRIEN** (e-mail: mbrien@ufl.edu), **MICHAEL S. CHERKISS** (e-mail: mcherkis@ufl.edu), and **FRANK J. MAZZOTTI**, Department of Wildlife Ecology and Conservation, University of Florida, Fort Lauderdale Research and Education Center, 3205 College Avenue, Davie, Florida 33314, USA (e-mail: fjma@ufl.edu).

SONORA SEMIANNULATA (Ground Snake). **PREDATION**. *Sonora semiannulata* (Colubridae) is a small burrowing species that occurs in desert, grassland, and semi-arid forest formations throughout the southwestern U.S. and northern Mexico (Frost 1983. Cat. Amer. Amphib. Rept. 333.1–4). The snake feeds primarily on small arthropods, including venomous centipedes, and was assumed to have some physiological resistance to venom or behavioral attributes allowing for successful prey capture without being envenomated (Kassing 1961. Texas J. Sci. 13:185–203; Werler and Dixon 2000. Snakes of Texas: Identification, Distribution, and Natural History. Univ. Texas Press, Austin, Texas, 437 pp.). Consuming venomous arthropods by *S. semiannulata* is thus well established, but the reverse situation, the predation on that species by venomous arthropods, has not been documented. Here we present the first reported observation of predation on a *S. semiannulata* by the centipede, *Scolopendra heros*, a large (maximum 210 mm TL) and voracious species, with relatively toxic venom, which reportedly consumes about any animal it can overpower, including snakes (Maldonado 1998. The Taxonomy and Biology of Southwestern U.S. Scolopendrid Centipedes [Chilopoda: Scolopendridae]. M.S. Thesis, Dept. of Biol. Sci., The Univ. of Texas at El Paso, 110 pp.). As an example, Easterla (1975. Southwest. Nat. 20:411) described a 118 mm (TL) *S. heros* eating a freshly killed 247 mm (TL) Long-nosed Snake, *Rhinocheilus*

FIG. 1. A *Scolopendra heros* examining a freshly killed *Sonora semiannulata* prior to devouring its soft body parts.

lecontei, near Study Butte, Brewster Co., Texas, and noted that soft portions of the head and neck of the snake were consumed first.

On 12 June 2003 at 0916 h, while lifting a pitfall trap cover board, a large *S. heros* (ca. 203 mm TL) was observed killing and then eating a *Sonora semiannulata* (ca. 218 mm TL; Fig. 1) near the headquarters of Indio Mountains Research Station (IMRS), Hudspeth Co., Texas (30°46'35"N, 105°00'55"W; 1215 m elev.). The local environment at the observation site was a sloping alluvial fan covered by Chihuahuan Desert scrub vegetation. Estimating length, which was determined by using a string to measure each animal, was necessary due to IMRS policy prohibiting unnecessary disruption of animals engaged in natural behavior. Fortunately, the centipede could be realistically measured since the animal ignored us while feeding. The snake was still alive when first discovered, but obviously incapacitated by either the centipede's venom or by other trauma associated with the attack. Even though the centipede was shorter than the snake, it nonetheless had a more massive body and in all probability had little difficulty initially overpowering its weaker prey. Surveillance of ensuing feeding behavior confirmed that the snake was being consumed from the head backward along the body (similar to that reported by Easterla, *op. cit.*). Soft parts were devoured flush to the vertebrae and ribs while the centipede made circular bites around the snake's torso. The feeding process was tracked for about 20 minutes, after which time the centipede carried away the half-eaten snake and disappeared into nearby vegetation. Fig. 1 and another digital photograph depicting the centipede consuming the snake are deposited in the photograph collection, Laboratory for Environmental Biology, Centennial Museum, The University of Texas at El Paso (UTEP G2005.1.1–1.2).

THAMNOPHIS CYRTOPSIS (Black-necked Gartersnake). **BEHAVIOR**. On 12 August 2004, one of us (EWS) captured a small (179 mm SVL, 2.0 g), male *T. cyrtopsis* with a noticeable food bulge in a creek in the Rincon Mountains, Saguaro National Park, Arizona, USA. As the snake was readied for processing it was held loosely, during which time it coiled itself into a knot. The snake was looped into a circle with a coil around its body directly posterior of its head. The coil was tight and it seemed strength was gained by buttressing the anterior ventral surface against the top of the head. Proceeding posteriorly from the first loop, the tail was brought back under its head and another coil was looped around its body, anterior to the first loop. Here, it appeared strength was gained by buttressing against the side of the head. The end of the tail was placed against the top of the snake's head, giving the appearance that leverage was gained by the tail's placement. The combination of coils circling the body and bracing of body parts made for a very tight structure; the snake could literally be held by the long section of its body with the coiled head and tail remaining stiff and inflexible (Fig. 1). To our knowledge, this behavior has not been reported for any *Thamnophis*. Veer et al. (1997. Herpetol. Rev. 28:91) report similar behavior by *Sonora semiannulata* in response to attempted predation by *Micruroides euryxanthus*. Their report describes a behavior whereby a *Sonora* formed a loop that (temporarily) stymied predation by grasping itself behind its own head, forming a loop that the *Micruroides* "walked over" as it maneuvered to find the ground snake's head. Given that *T. cyrtopsis* is sympatric with *M. euryxanthus* and other ophidiophagous snakes (e.g., *Lampropeltis* spp., *Masticophis* spp., *Diadophis punctatus*), the unique behavior we observed may provide a similar defensive role.

FIG. 1. *Thamnophis cyrtopsis* showing presumed defensive behavior.

Submitted by **ERIC W. STITT**, School of Natural Resources, 125 Biological Sciences East, University of Arizona, Tucson, Arizona 85721, USA (e-mail: estitt@u.arizona.edu); and **DON E. SWANN,** National Park Service, Saguaro National Park, Tucson, Arizona 85730, USA.

THAMNOPHIS MARCIANUS MARCIANUS (Checkered Garter Snake). **DIET**. Although a wide variety of taxa, including invertebrates, fish, lizards, snakes, and mammals, are considered part of its diet, *Thamnophis marcianus* preys most frequently on amphibians (reviewed in Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Inst. Press, Washington,

D.C. 668 pp.). Only two species of lizard (*Cophosaurus texanum* and *Holbrookia maculata*) have been previously documented as prey items of *T. marcianus*. This is a report of the first documented occurrence of a teiid lizard, *Aspidoscelis inornatus*, as a prey item of *T. marcianus*.

On 3 August 2006 a *T. marcianus* (ca. 70 cm TL) was found crossing Highway 380, ca. 11 miles E of Roswell, Chaves Co., New Mexico, USA (33°23.843'N, 104°25.296'W). Upon capture, the snake readily regurgitated the remains of an *A. inornatus*.

Submitted by **PAUL M. HAMPTON**, Department of Biology, University of Louisiana at Lafayette, Lafayette, Louisiana 70504, USA; and **BRIAN E. FONTENOT**, Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA.

THAMNOPHIS PROXIMUS PROXIMUS (Western Ribbon Snake). **NECROPHAGY**. Reports of necrophagy in snake species, although uncommon, have previously been documented, particularly with roadkill as the food item (Teixeira and Vrcibradic 2003. Herpetol. Rev. 34:248). The diet of *Thamnophis proximus* is broad, consisting of several salamanders, frogs, toads, and fish species (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. University of Oklahoma Press, Norman, Oklahoma. 332 pp.). This is the first published account necrophagy by *T. proximus*.

On 9 April 2005, a female *T. proximus* (679 mm SVL, 99 g) with an obvious prey bulge was captured at the Old Sabine Bottom Wildlife Management Area, Smith Co., Texas, USA (32°36.156'N, 95°20.329'W). An *Ambystoma texanum* (56 mm SVL, 2 g) was removed. The salamander was ingested mid-body first and appeared to have desiccated prior to ingestion as evidenced by sunken eyes and shrunken leathery skin. The salamander was also rigid, which is inconsistent with the generally soft body of palped amphibian prey. Little digestion was apparent, also inconsistent with other palped prey items. Given the condition of the food item, it is most likely that the item was eaten post-mortem.

Submitted by **PAUL M. HAMPTON**, Department of Biology, University of Texas at Tyler, 3900 University Blvd, Tyler, Texas 75799, USA.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother 2000. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, with Comments Regarding Confidence in Our Understanding*. SSAR Herpetol. Circ. 29:1–82, available online at <http://herplit.com/SSAR/circulars/HC29/Crother.html>; for Mexico as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish.* Herpetol. Circ. 23:1–113), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author—curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al. 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985[3]:802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full—spell out state or province names—no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*; available from the SSAR Publications Secretary) and other sources to make sure you are not duplicating a previously published record. The responsibility for checking literature for previously documented range extensions lies with authors. Do not submit range extensions unless a thorough literature review has been completed.

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: **Alan M. Richmond** (USA & Canadian records only); **Jerry D. Johnson** (Mexico and Central America, including the Caribbean Basin); **Indraneil Das** (all Old World records); or **Gustavo J. Scrocchi** (South American records). Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Electronic submission of manuscripts is required** (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments)**.** Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Schmitz, A., and T. Ziegler. 2003. Geographic distribution. *Sphenomorphus rufocaudatus*. Herpetol. Rev. 34:385.

CAUDATA

AMBYSTOMA MACULATUM. (Spotted Salamander). USA: TENNESSEE: LAUDERDALE CO.: John Tully Wildlife Management Area managed by the Tennessee Wildlife Resources Agency located in the Golddust 7.5 minute Quad (35.66007°N, 89.803250°W, NAD 83). 17 October 2006. Daniel Stanfield of the Tennessee Wildlife Resources Agency. Austin Peay State University Museum of Zoology (APSU 18243). Verified by A. Floyd Scott. One Spotted Salamander found while conducting a visual encounter survey in bottomland hardwoods. Temperature at collection was 22°C. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.; hard copy and Internet versions, the latter of which includes links to information on Tennessee amphibians having appeared since 1996, http://www.apsu.edu/amatlas/, accessed 19 October 2006).

Voucher image collection made under the authority of the Tennessee Wildlife Resources Agency; field work supported by State Wildlife Grant (SWG) funding under the authority of the U.S. Fish and Wildlife Service.

Submitted by **CHRIS HUNTER**, Tennessee Wildlife Resources Agency, 200 Lowell Thomas Drive, Jackson, Tennessee 38301, USA; e-mail: christopher.hunter@state.tn.us.

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: TENNESSEE: LAUDERDALE CO.: John Tully Wildlife Management Area managed by the Tennessee Wildlife Resources Agency and located

in the Golddust 7.5-minute Quad (35.65639°N, 89.800450°W, NAD 83). 17 October 2006. Daniel Stanfield of the Tennessee Wildlife Resources Agency. Austin Peay State University Museum of Zoology (APSU 18244). Verified by A. Floyd Scott. One individual found while conducting a visual-encounter survey in bottomland hardwoods near Goose Pond. Temperature at collection was 23°C. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.; hard copy and Internet versions, the latter of which includes links to information on Tennessee amphibians having appeared since 1996, http://www.apsu.edu/amatlas/, accessed 19 October 2006).

Voucher image collection made under the authority of the Tennessee Wildlife Resources Agency; field work supported by State Wildlife Grant (SWG) funding under the authority of the U.S. Fish and Wildlife Service.

Submitted by **CHRIS HUNTER**, Tennessee Wildlife Resources Agency, 200 Lowell Thomas Drive, Jackson, Tennessee 38301, USA; e-mail: christopher.hunter@state.tn.us.

AMBYSTOMA TIGRINUM TIGRINUM (Eastern Tiger Salamander). USA: ILLINOIS: Hamilton Co.: Hamilton County State Fish and Wildlife Area, vernal pond ca. 500 m S of the Dolan Lake spillway parking lot (38°03'05"N, 88°24'08"W). 15 April 2006. Cy L. Mott and Michael A. Steffen. Verified by Ronald A. Brandon. SIUC H-08673. Larval specimen. New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. xii + 282 pp.).

Submitted by **CY L. MOTT**, Cooperative Wildlife Research Laboratory, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA; e -mail: cm8755@siu.edu.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: INDIANA: Henry Co: 2.4 km S of Springport (Minton 1998. *In* M. J. Lannoo [ed.], Status and Conservation of Midwestern Amphibians. Univ. Iowa Press, Iowa City). 01 April 2006. Kelly Jones. Verified by Michael J. Lannoo. INHS voucher photo INHS 2006d. Gravid female 39 mm SVL, 54 mm TL with partly regenerated tail seen climbing out of the water onto a moss-covered log at approximately 0030 h EST. Previously thought to be extirpated from site. First sighting of this species at this site and in this county in ~30 years (James List, pers. comm.).

Submitted by **KELLY JONES**, 6207 Welham Road, Indianapolis, Indiana 46220, USA; e-mail: kellyjones78@yahoo.com.

PLETHODON GLUTINOSUS (Northern Slimy Salamander). USA: OHIO: Preble Co.: Israel Township. Hueston Woods State Park (39°34.4627'N, 83°44.6420'W). 11 June 2006. Jeffrey G. Davis. Verified by John W. Ferner. Cincinnati Museum Center (CMNH 8970). New county record (Pfingsten and Matson 2003. Ohio Salamander Atlas. Ohio Biological Survey Misc. Contribution No. 9, Columbus).

Submitted by **JEFFREY G. DAVIS,** Cincinnati Museum Center – Fredrick and Amye Geier Research and Collections Center, 1301 Western Avenue, Cincinnati, Ohio 45203-1130, USA; e-mail: anura@fuse.net.

ANURA

AMOLOPS KAULBACKI (Kaulback's Torrent Frog). INDIA: MIZORAM: Lunglei District: Small stream at Theiriat, Lunglei (22º48'–52'N, 92º48'–53'E; 1050 m elev.). Male, SVL 67.5 mm. 14 August 2003 at ca. 2030 h. Department of Zoology Museum, North Eastern Hill University Collection HT 0004. H. T. Lalremsanga, Saipari Sailo, and R. N. K. Hooroo. Verified by Saibal Sengupta. Previously reported from Northern Myanmar (Smith 1940. Rec. Indian Mus. 42:465–486; Pl. VIII). New record for India.

Submitted by **SAIPARI SAILO** (e-mail: spsailo@yahoo.co.in), **H. T. LALREMSANGA** (e-mail: htlrsa@yahoo.co.in), and **RUPA NYLLA K. HOOROO** Department of Zoology, Developmental Biology Laboratory, North Eastern Hill University, Shillong 793 022, Meghalaya, India; e-mail: rnkhnehu@hotmail.com.

BUFO BOREAS (Western Toad). USA: IDAHO: Nez Perce Co.: Gravel access road S of Route 12 near Idaho Department of Transportation gravel pit (46°27.846'N, 116°46.820'W) 253 m elev. 29 October 2006. Alex Dornburg. Verified by Kenneth V. Kardong. Photo voucher deposited in the Washington State University Conner Museum Collection (CRCM-P-29) Juvenile was found under cover object near gravel pathway adjacent to train tracks. Ambient temperature at time of encounter was 12°C. First county record. This record fills a gap in distribution data, as this species has been documented in adjacent Latah, Clearwater, and Idaho counties (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. University of Idaho Press, Moscow, Idaho, 332 pp.).

Submitted by **ROBERT E. WEAVER** (e-mail: weaverr@wsu.edu) and **ALEX DORNBURG**, School of Biological Sciences, Washington State University, Pullman, Washington 99164, USA (e-mail: dornburgalex@yahoo.com).

BUFO FOWLERI (Fowler's Toad). USA: OHIO: Miami Co.: Spring Creek Township, Statler Road (40°07'54.9"N, 84°08'20.5"W). 29 August 2004. Jeffrey G. Davis and Paul J. Krusling. Verified by John W. Ferner. Cincinnati Museum Center (CMNH 9778–9779). New county record (Davis and Menze 2000. Ohio Frog and Toad Atlas. Ohio Biological Survey Misc. Contributions No. 6, Columbus).

Submitted by **JEFFREY G. DAVIS (**e-mail: anura@fuse.net) and **PAUL J. KRUSLING**, Cincinnati Museum Center – Fredrick and Amye Geir Research and Collections Center, 1301 Western Avenue, Cincinnati, Ohio 45203-1130 USA (e-mail: pkrusling@fuse.net)**.**

BUFO MELANOSTICTUS (Asian Toad). WEST MALAYSIA: PERAK: CAMERON HIGHLANDS: Robinsons Falls Trail (04°28.318'N, 101°22.634'E) (La Sierra University Herpetological Collection 6596). 16 August 2004. Male; SVL 82 mm. Collected at night on a cement trail. Timothy M. Youmans, Perry L. Wood Jr. Verified by L. Lee Grismer. Known from Sri Lanka, Burma, Thailand, China, West Malaysia, Bali, Borneo, India (Manthey and Grossmann 1997. Amphibien und Reptilien Südostasiens. Natur und Tier-Verlag, Münster. 512 pp.). This specimen is a new record for Cameron highlands (Lim et al. 2002. J.

Wildl. Parks, Kuala Lumpur 20:49–57).

Submitted by **TIMOTHY M. YOUMANS** (e-mail: timoyoum@lasierra.edu) and **PERRY L. WOOD, JR.** (e-mail: perrwood@lasierra.edu), Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

BUFO WOODHOUSII (Woodhouse's Toad). USA: NEW MEXICO: LEA CO.: NM Hwy 508; 19.66 mi N, 10.62 mi E Tatum (jct. US Hwy 380 and NM Hwy 206); T9S, R37E, boundary of S11 (SW 1/4) and S14 (NW 1/4); 13S, 3712898N, 0673517E (WGS 84). MSB 72602. 09 July 2006 by Michael T. Hill, Taylor B. Cotten, and Clayton D. Crowder. Verified by Charles W. Painter. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. University of New Mexico Press, Albuquerque. 431 pp.).

Submitted by **MICHAEL T. HILL, TAYLOR B. COTTEN**, Department of Wildlife and Fisheries Sciences, Texas A&M University, 2258 TAMU, College Station, Texas 77843, USA; and **CLAYTON D. CROWDER**, 14 Mountain Laurel, Los Lunas, New Mexico 87031, USA.

CHAUNUS PYGMAEUS. BRAZIL: ESPÍRITO SANTO: MIMOSO DO SUL MUNICIPALITY: 21°03'48"S, 41°23'23"W, 279 m elev. 01–05 November 2001. G. Ramos da Silva. Herpetological Collection, Departamento de Zoologia, Universidade Federal do Rio de Janeiro, Rio de Janeiro (ZUFRJ 8987–8989, males, calling in a temporary muddy pond). Verified by E. Izecksohn. Previously known only from Rio de Janeiro State, in coastal Brazil, where it occurs at very low elevations, from sea level up to only 50 m, in restingas (Carvalho-e-Silva et al. 2000. *In* F. A. Esteves and L. D. Lacerda [eds.], Ecologia de Restingas e Lagoas Costeiras, pp. 89–97. Nupem/Universidade Federal do Rio de Janeiro, Macaé, Rio de Janeiro). First state record and the first outside of restingas, where it was thought to be endemic. Extends range ca. 90 km NW from São Joao da Barra (Myers and Carvalho 1952. Zoologica 37:1–3.).

Submitted by **GUILHERME RAMOS DA SILVA** (e-mail: grscinax@gmail.com), **SERGIO POTSCH DE CARVALHO-E-SILVA** (e-mail: sergio@biologia.ufrj.br), and **ANA MARIA PAULINO TELLES DE CARVALHO-E-SILVA,** Departamento de Zoologia, Universidade Federal do Rio de Janeiro, caixa postal 68.044, CEP 21944-970, Cidade Universitária, Rio de Janeiro, Brazil (e-mail: atelles@unirio.br).

HYLA CINEREA (Green Treefrog). USA: TENNESSEE: HAMILTON CO.: 1278 Enclave Road, Chattanooga (35°05'39.7"N, 085°16'32.3"W). 24 September 2006. Ashley Miller and Thomas Wilson. Verified by John Jensen, Georgia DNR. The University of Tennessee at Chattanooga Natural History Museum (UTCA 187–188). Two deceased adult individuals collected from residential driveway. Fourteen individuals counted the previous day following heavy rain. Species previously reported from adjacent Marion County (Davenport et al. 2005. Herpetol. Rev. 36: 209–210). Represents first verified record for Hamilton County (Conant and Collins 1998. Reptiles and Amphibians: Eastern/ Central North America 3rd ed., expanded. Houghton Mifflin Co., Boston, Massachusetts, 616 pp.; Redmond and Scott 1996. Atlas of Amphibians in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. http//www.apsu.edu/amatlas/). Collection made under Tennessee Wildlife Resources Agency Permit 1534.

Submitted by **ASHLEY MILLER**, **THOMAS P. WILSON**, **MATTHEW B. SMITH**, **ROBERT MINTON**, and **CHRIS MANIS**, Department of Biological and Environmental Sciences, The University of Tennessee at Chattanooga, 615 McCallie Avenue, Chattanooga, Tennessee 37403, USA.

HYLA CINEREA (Green Treefrog) USA: TEXAS: BREWSTER CO.: Big Bend National Park: Rio Grande Village beaver pond. 29°10' 46"N, 102°57'12"W. 30 September 2006. Collected by D. J. Leavitt and T. C. Mullet. Verified by Steven G. Platt. Sul Ross State University J. F. Scudday Vertebrate Collection (SRSU 1502); one froglet found atop a submersed bunchgrass in thick vegetation. New county record and non-native (Dixon 2000. Reptiles and Amphibians of Texas. Texas A&M Univ. Press, College Station. 500 pp.) The location is near a frequently visited campground, suggesting inadvertent translocation. Dayton (2002. Amphibians and Reptiles Checklist: BBNP. BBNHA, BBNP) lists this species as hypothetical based on vocalizations heard at the Rio Grande Village beaver pond. This coupled with the age of the individual suggests an established breeding population.

Submitted by **DANIEL J. LEAVITT**, **TIMOTHY C. MULLET**, and **CHRISTOPHER M. RITZI**, Biology Department, Sul Ross State University, Alpine, Texas 79832, USA; and **J. RAYMOND SKILES**, National Park Service, Big Bend National Park, Texas 79834, USA.

HYLA VERSICOLOR (Gray Treefrog). USA: OHIO: TUSCARAWAS CO.: York Township. County Road 21 (40°28'39.2"N, 81°29'17.6"W). 27 July 2005. Danielle K. Thompson. Verified by John W. Ferner. Cincinnati Museum Center (CMNH Herp Photodocumentation Collection HP 250–251). New county record (Davis and Menze 2000. Ohio Frog and Toad Atlas, Ohio Biological Survey Misc. Contrib. No. 6, Columbus).

Submitted by **DANIELLE K. THOMPSON**, Institute of Environmental Sciences, Miami University, 102 Boyd Hall, Oxford, Ohio 40056, USA (e-mail: thompsondk@muohio.edu); and **JEFFREY G. DAVIS**, Cincinnati Museum Center – Fredrick and Amye Geier Research and Collections Center, 1301 Western Avenue, Cincinnati, Ohio 45203-1130, USA (e-mail: anura@fuse.net).

KALOPHRYNUS ORANGENSIS (Orang Sticky Frog): INDIA: WEST BENGAL: JALPAIGURI DISTRICT: Mendabari Range, Chilapata Reserve Forest (26º20'N, 89º25'E). 13 October 2006. Subhadip Paul. ZSIC A.10402. Verified by Sushil Kumar Dutta. Adult male, SVL 34.6 mm found calling from a bush, 60 cm above ground adjacent to Bong Basti Forest Village within primary semi-evergreen forest. Previously known from Orang National Park, 26º32'N, 92º15'E, Darrang District, eastern Assam, India (Dutta et al. 2000. Hamadryad 25:67–74). Westward range extension by ca. 320 km, and a new record for West Bengal State.

Submitted by **SUBHADIP PAUL**, Village Birpara, District Jalpaiguri, P.O. Alipurduar 736 121, West Bengal, India; **MANINDRA CHANDRA BISWAS**, Divisional Forest Officer, Cooch Behar Forest Division, Nilkuthi, Cooch Behar 736 101, West Bengal, India; and **KAUSHIK DEUTI**, Zoological Survey

of India, Nizam Palace, Kolkata 700 020, West Bengal, India (e-mail: kaushikdeuti@rediffmail.com).

LEPTOBRACHIUM SMITHI (Smith's Litter Frog). INDIA: MIZORAM: KOLASIB DISTRICT: Kawnpui (22º58'17.6"N, 92º41'34.8"E; 305 m elev.). Female, SVL 65.2 mm, found near small stream. 25 June 2006 at ca. 2000 h. Department of Zoology Museum, North Eastern Hill University Collection MZ 0100. Saipari Sailo, H. T. Lalremsanga, and R. N. K. Hooroo. Verified by Saibal Sengupta. Known from Assam State in northeast India, Myanmar, Thailand, and northern Malay Peninsula (Matsui et al. 1999. Japan. J. Herpetol. 18[1]:19–29; Sengupta et al. 2001. J. Bombay Nat. Hist. Soc. 98[2]:289–291; Das and Chanda 2004. Asiatic Herpetol. Res. 10:245–246). New state record for Mizoram State.

Submitted by **H. T. LALREMSANGA** (e-mail: htlrsa@yahoo.co.in), **SAIPARI SAILO** (e-mail: spsailo@yahoo.co.in), and **RUPA NYLLA K. HOOROO,** Department of Zoology, Developmental Biology Laboratory, North Eastern Hill University, Shillong 793 022, Meghalaya, India (e-mail: rnkhnehu@hotmail.com).

PHYLLOMEDUSA ROHDEI (Rohde's Leaf Frog). BRAZIL: BAHIA: Uruçuca (14º35'12"S; 39º17'23"W; ca. 100 m elev.). 16 August 2004. O. G. S. Araújo, L. F. Toledo, D. Loebmann, and J. Zina. Verified by C. F. B. Haddad. Coleção de anuros Célio F. B. Haddad, Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, Rio Claro, São Paulo, Brazil (CFBH 13189–93). Previously known from the states of Rio de Janeiro (Rio de Janeiro, Teresópolis, and Saquarema Municipalities), São Paulo; Minas Gerais and Espírito Santo, Brazil (Frost 2006. Amphibian Species of the World: an Online Reference. Version 4. http://research.amnh.org/herpetology/amphibia/index.php; Wogel et al. 2005. J. Nat. Hist. 39:2035–2045; Sazima 1974. J. Herpetol. 8:376–377; Feio et al. 1998. Anfíbios do Parque Estadual do Rio Doce [Minas Gerais]. Universidade Federal de Viçosa, Viçosa, Brazil, 32 pp.; Vrcibradic et al. 2006. Herpetol. Rev. 37:101). First state record, extends the species distribution ca. 470 km N from the municipality of Nova Venécia, state of Espírito Santo (Vrcibradic et al., *op. cit.*) and ca. 780 km N from the municipality of Viçosa, state of Minas Gerais (Feio et al., *op. cit.*).

Submitted by **OLÍVIA GABRIELA DOS SANTOS ARAÚJO**, **DANIEL LOEBMANN**, **JULIANA ZINA**, and **LUÍS FELIPE TOLEDO**, Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, Caixa Postal 199, CEP 13506-970, Rio Claro, São Paulo, Brazil (e-mail: oliviaaraujo@gmail.com).

PIPA ARRABALI **(**Arrabal's Surinam Toad**)**. BRAZIL: RONDÔNIA: PIMENTA BUENO MUNICIPALITY, Parque Municipal de Pimenta Bueno (11º40'21"S, 61º11'35"W). 20 February 2006. B. L. Sousa. Herpetological collection of Universidade Federal do Acre – UFAC, Campus Floresta, Cruzeiro do Sul, Acre (UFACF 079). Verified by R. A. Machado. Species was previously known from Guyana, Surinam, eastern Venezuela, and northern Brazil in the Amazonas and Pará states (Trueb and Cannatella 1986. Herpetologica 42[4]:412–449; Zimmerman and Rodrigues 1990. *In* Gentry [ed.], Four Neotropical Rainforests, pp. 426–454; Barrio-Amorós 1999 "1998." Acta Biol. Venezuel. 18:59). First state record, extends the range of this species 710 km SW from the Serra do Cachimbo, Novo Progresso municipality, Cristalino River, Pará State (Garda et al. 2006. S. Amer. J. Herpetol. 1[1]:20–24).

Submitted by **BRUNO LOPES DE SOUSA**, Faculdade de Ciências Biomédicas de Cacoal – FACIMED, Av. Cuiabá 3033, Jardim Clodoaldo, CEP: 78.976-005 Cacoal, RO, Brazil (e-mail: brunosousa_biologo@hotmail.com); and **PAULO SÉRGIO BERNARDE**, Centro de Ciências Biológicas e da Natureza, Campus Floresta, Universidade Federal do Acre – UFAC, CEP: 69980-000 Cruzeiro do Sul, AC, Brazil (e-mail: paulobernarde@uol.com.br).

PSEUDACRIS BRACHYPHONA (Mountain Chorus Frog). USA: GEORGIA: WALKER CO.: Roadside pool along Georgia Hwy 157, 7.2 km N of jct. with Moon Lake Road, on top of Lookout Mountain. 4 March 2004. John B. Jensen and Carlos D. Camp. GMNH 49903–04. Verified by Elizabeth McGhee. First county record and first Georgia record within the Cumberland Plateau physiographic province. Extends range ca. 45 km E of nearest record (Jackson Co., Alabama; Mount 1975. Reptiles and Amphibians of Alabama. Auburn University Agricultural Experiment Station, Auburn, Alabama). Many males were issuing breeding calls during daylight hours.

Submitted by **JOHN B. PSEUDACRIS CRUCIFER (Spring Peeper). USA: ILLINOIS: GALLATIN CO.: Shawnee National Forest, vernal pond ca. 1 km from Pounds Hollow Rd. on York Lane Rd. (37°36'14"N, 88°15'46"W). 04 March 2006. Cy L. Mott, Michael A. Steffen, John M. Uzzardo, and Brian K. Willey. Verified by Ronald A. Brandon. Color photo voucher. SIUC H-08676. New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. xii + 282 pp.).

Submitted by **CY L. MOTT**, Cooperative Wildlife Research Laboratory, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA; e - mail: cm8755@siu.edu.

PSEUDACRIS C. CRUCIFER (Northern Spring Peeper). USA: OHIO: MIAMI CO.: Newton Township. Brukner Nature Center (40° 00'53.9"N, 84°19'18.56"W). 13 April 2002. Jeffrey G. Davis and Paul J. Krusling. Verified by John W. Ferner. CMNH 9141–9142. New county record (Davis and Menze 2000. Ohio Frog and Toad Atlas, Ohio Biological Survey Misc. Contribution No. 6. Columbus).

Submitted by **JEFFREY G. DAVIS (**e-mail: anura@fuse.net**)** and **PAUL J. KRUSLING**, Cincinnati Museum Center – Fredrick and Amye Geier Research and Collections Center, 1301 Western Avenue, Cincinnati, Ohio 45203-1130, USA (e-mail: pkrusling@fuse.net).

PSEUDACRIS PACIFICA (Pacific Treefrog). USA: IDAHO: NEZ PERCE CO.: 30 m S of Route 12 near train tracks along the Clearwater River (46°28.234'N , 116°46.481'W) 258 m elev. 27 October 2006. Chad D. Brock. Verified by Kenneth V. Kardong. Photo voucher deposited in the Washington State University Conner Museum Collection (CRCM-P-28). Two adults were found sharing a cover object. Ambient temperature at time of collection was 16°C. First county record. Field guides depict the range of this species as continuous throughout most of northern and western Idaho (Jones et al. 2005. Amphibians of the Pacific Northwest. Seattle Audobon Society, Seattle, Washington), however, its presence in north-central Idaho is poorly documented. This record fills a distributional gap, as localities for this species have been reported for adjacent Latah and Idaho counties (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. University of Idaho Press, Moscow, Idaho).

SCINAX GRANULATUS. ARGENTINA: BUENOS AIRES: PARTIDO DE GENERAL MADARIAGA: (37º01'09"S, 57º06'57"W). 20 September 2005. R. Cajade and D. A. Barrasso. Verified by J. Williams. Herpetological collection Museo de La Plata, Buenos Aires, Argentina (MLP.A. 4922–24). Species previously known from southern Brazil, southeastern Paraguay, northeastern Argentina, and Uruguay (Cei 1980. Monitore Zoologico Italiano N.S. 2:1–609; Aquino et al. [eds.] 1996. O.R.: 331– 400; Kwet 2001. Salamandra 37:211–238). Previously, the southernmost locality supported by voucher specimens was Pereyra Iraola, Partido de La Plata, Buenos Aires province, Argentina (Gallardo 1961. Com. Mus. Arg. Cien. Nat. "Bernardino Rivadavia" III [5]:145–158). Gallardo (*op. cit.*) mentioned two specimens from Sierra de la Ventana, located 450 km WSW from General Madariaga, but this record is not supported by voucher specimens. Therefore, the present account establishes a new southern vouchered record for *Scinax granulatus* and extends the range of the species ca. 250 km S from La Plata.

Submitted by **BARRASSO DIEGO A.** and **RODRIGO CAJADE**, Centro de Investigaciones del Medio Ambiente, Departamento de Química, Facultad de Ciencias Exactas, UNLP, 47 y 115 (CP 1900), La Plata, Bs. As., Argentina.

TESTUDINES

CHELYDRA SERPENTINA (Common Snapping Turtle). USA: ILLINOIS: FRANKLIN CO.: Snapping turtle was live caught from an ephemeral pool located on Wayne Fitzgerrell State Park just east of Fitzgerrell Park Road. GPS coordinates are as follows: N 0331325 and W 4219341, zone 16 using NAD27 CONUS map datum in UTM's. 08 March 2006, 2339 h. James T. Lamer and Chad R. Dolan, Illinois Natural History Survey. INHS 2006.59 Verified by Chris Phillips, Illinois Natural History Survey. Specimen is a photographic record and first county record. Photograph is located at the Illinois Natural History Survey in Champaign/Urbana, Illinois (Phillips 1999. Field Guide to Amphibians and Reptiles of Illinois). Turtle was kicked up while wading in pool and then hand caught during steady rainfall with an air temperature of 18.3°C. The following measurements were recorded: carapace length = 324 mm, carapace width = 287 mm, carapace height = 123 mm, plastron length = 222 mm, and mass = 9000 g.

Submitted by **JAMES T. LAMER, CHAD R. DOLAN,** and **JOHN K. TUCKER,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

CHRYSEMYS PICTA DORSALIS (Southern Painted Turtle). USA: ARKANSAS: MONROE CO.: On US Hwy 49, 0.5 mi N of Hwy 79; 34°42.364'N, 91°08.916'W (WGS 84): 22 Apr. 2005. Josh Engelbert and Melissa Patrick. Verified by Stanley E. Trauth. Voucher specimen in Arkansas State University Museum of Zoology (ASUMZ 29270). New county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville, 421 pp.).

Submitted by **JOSH ENGELBERT** and **MELISSA PATRICK**, Department of Biological Sciences, Arkansas State University, P.O. Box 599, State University, Arkansas 72467-0599, USA (e-mail: josh.engelbert@smail.astate.edu).

EMYDOIDEA BLANDINGII (Blanding's Turtle). USA: WISCONSIN: OZAUKEE CO.: Mud Lake, Cedarburg Bog State Natural Area (43°22'39"N, 88°01'24"W, NAD27). 2–4 June 2006. Joshua

M. Kapfer and Timothy Muehlfeld. Verified by Christopher A. Phillips. INHS 2007a. New county record, fills gap where species occupies all neighboring counties (Casper 1996. Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, 87 pp.) and confirms several prior observational reports.

LACERTILIA

EMOIA ATROCOSTATA (Littoral Skink). USA: GUAM: INARAJAN MUNICIPALITY: 400 m S of Inarajan town center, Inarajan Pool public park (13.271356°N; 144.74748°E, determined in WGS84 map projection), on raised limestone under *Pemphis acidula* shrub in high-energy coastal habitat. 07 September 2006. R. N. Reed. Verified by B. Lardner. USNM 563345. First record for the island of Guam. Three additional individuals observed in same area on this date. *E. atrocostata* is known from Cocos Island, Anae Islet, and Agrigan Islet, all just off the coast of Guam, as well as on several islands in the northern Marianas, but had not previously been documented on Guam proper.

Submitted by **ROBERT N. REED** (e-mail: robert_reed@usgs.gov), **GORDON H. RODDA**, and **THOMAS J. HINKLE**, U.S. Geological Survey, Fort Collins Science Center, 2150 Centre Ave, Bldg C, Fort Collins, Colorado 80526, USA.

HEMIDACTYLUS PLATYURUS (Flat-tailed Gecko). MALAYSIA: PAHANG: CAMERON HIGHLANDS: The Cool Point Hotel in Tanah Rata (04°28.318'N, 101°22.634'E). La Sierra University Herpetological Collection 6636. 17 August 2004. Male (SVL 54 mm, TL 61.5 mm) found ca. 1.5 m above ground on cement wall. Perry L. Wood, Jr. and Timothy Youmans. Verified by L. Lee Grismer. Previously known from India, Sri Lanka, Myanmar, Thailand, Vietnam, China, Taiwan, West Malaysia, Singapore, Borneo, Sumatra, Java, Sulawesi, Lombok, Sumbawa, Flores, New Guinea, and the Philippines (Manthey and Grossmann 1997. Amphibien und Reptilien Südostasiens. Natur und Tier Verlag, Münster. 512 pp.). New record for Cameron Highlands (Lim et al. 2002. J. Wildlife & Parks 20:49–57).

Submitted by **PERRY L. WOOD** (e-mail: pwoo213@my.lasierra.edu) and **TIMOTHY YOUMANS** (e-mail: tyou101@my.lasierra.edu), Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

LACERTA BILINEATA (Western Green Lizard) and ***PODARCIS MURALIS*** (Common Wall Lizard). UNITED KINGDOM: DORSET: Bournemouth Cliffs: Portman Ravine (01°43'W, 50°43'N). *Lacerta bilineata* were probably released at Portman Ravine circa 1995, but possibly earlier. An expanding colony of *L. bilineata* has now established itself along a 1.5 km stretch of cliff and cliff-top. Animals of all age classes can be seen basking around the margins of gorse (*Ulex major*) stands and in other scrub, herbs, and dune grasses. Observation over the last three years suggest that the animals are becoming more numerous, visible, and widespread. A population of *Podarcis muralis* became established at the same location around the same time, but does not appear to have extended as widely. The origins of both introductions are unknown. Gleed-Owen (2004. Herpetol. Bull. 2004:88,3–7) described the discovery of the population in 2002 and its subsequent monitoring. *L. bilineata* have been seen up to 550 m W and 1050 m E of the 'core area' at Portman Ravine, and a single animal has been seen 3.2 km W of the core area. This latter sighting raises suspicions that releases might be occurring. There are *Podarcis muralis* populations elsewhere on the cliffs of Poole Bay, and in other parts of southern England, but this is the only known *L. bilineata* population in Britain. The absence of *Lacerta agilis* from this part of Poole Bay has raised concerns that *L. bilineata* or *P. muralis* might be competitively displacing them, but historical reprofiling of the cliffs offers an alternative explanation. *Zootoca vivipara* is extant in the area and is being monitored by CGO for a possible decline as a consequence of the introduction of two lizard species alien to the United Kingdom. In continental Europe, there are numerous anecdotal reports and speculations on a negative effect of introduced *P. muralis* on native *Z. vivipara* and *L. agilis*. Only D. Münch (2001. Dortmunder Beiträge zur Landeskunde 35:187–190) provides data. He quantifies the duration of coexistence of introduced *P. muralis* and native *Z. vivipara* as 10 years, after which the latter were no longer observed in the area investigated near the city of Dortmund, Germany.

An autotomized tail of *Podarcis muralis* and two carcasses of *Lacerta* sp. (*viridis* or *bilineata*) was brought to one of us (CGO) between 03 and 11 May, 2005. CGO found another *Podarcis* tail at the frequently dog-walked site in this period. The tail tips were preserved in ethanol as tissue samples. No voucher specimens were retained. Total genomic DNA was extracted from each of the ethanol preserved tail tips, following a standard phenol-chloroform procedure. Amplifications of *cytochrome b* PCR fragments were performed in 25 µl reaction mixtures containing PCR buffer with 1.5 mM $MgCl_2$, 0.2 mM of each dNTP, 0.4 µM of each PCR primer, 0.5 units of *Taq* polymerase (Amersham). Reaction conditions comprised an initial denaturation step of 2 min at 94°C, 35 cycles of 10 s at 95°C, 15 s at 50°C, 50 s at 72°C, and a final extension step of 7 min at 72°C.

For *P. muralis* a 1019 bp long segment was amplified (primers: "sicnt-L" 5'-TTTGGATCCCTGTTAGGCCTCTGTT-3' and "H15906" 5'-GGTTTACAAGACCAGTGCTTT-3') and direct-sequenced (primers: "sicnt-L" and "murnum" 5'-AGGCACCTCCATAGTTCACC-3'). For the Green lizards the complete *cytochrome b* sequence was amplified using the primers NThe-H (5'-GGTTTACAAGACCAGTGCTTT-3') and LGluLK (5'-AACCGCTGTTGTCTTCAACTA-3'). PCR products were cloned using the TA vector (TOPO TA Cloning Kit, Invitrogen). Sequencing was performed by MWG sequencing service (Ebersberg, Germany).

The sequences of both *P. muralis* samples were identical and deposited at GenBank (accession number DQ646343). They were compared with homologous regions of sequences from samples scattered across the most of the range of *P. muralis* and which were analyzed in the course of a thorough genetic analysis of the species (Schweiger et al., unpubl.). The sequences of the Bournemouth samples were nearly identical to samples from the eastern Po plain and Friuli regions in Italy, and southern Slovenia. *P. muralis* from that region used to be assigned to subspecies *maculiventris*. However, since the systematics of *P. muralis* is currently under revision, we refrain from assigning a subspecies name to the Bournemouth population.

The sequence of one of the *Lacerta* sp. samples proved to be incomplete, possibly due to decay of the carcass. Amplified fractions of it were similar but not identical to the complete section of 807 bp gained from the other carcass. This complete section was compared with homologous sequences of *Lacerta viridis* from Austria, *Lacerta bilineata* from the Croatian island of Cres (Mayer, unpubl.) and GenBank sequences of *L. bilineata* samples from Italy. The sequences were most similar to samples from northern Italy and the island of Cres, proving that these specimens from the Bounemouth population belong to the latter species and are consistent with an origin similar to that of the *P. muralis*. The sequence was deposited at GenBank (accession number DQ646344).

Previously known from Paso Pehuenche and Valle Hermoso, Malargüe Department, Mendoza Province (Cei 1986. Mus. Reg. Sci. nat. Torino Monografie IV: 527 pp.; Pincheira and Nuñez 2005. Mus. Nac. His. Nat. Chile, Publ. Ocac. Nº 59:7–486). The present record extends the eastern range 135 km from Paso Pehuenche and 153 km from Valle Hermoso (Cei, *op. cit*.).

Submitted by **CRISTIAN ABDALA** (e-mail: popper@tucbbs.com.ar) and **CECILIA ROBLES,** Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina (e-mail: zezi74@hotmail.com).

LIOLAEMUS UMBRIFER. ARGENTINA: CATAMARCA PROVINCE: Tinogasta Department: Between Fiambalá and Cazadero Grande, 57 km NW of Fiambalá, 2800 m elev. (27º43'11.6"S, 68º08'29.52"W). 15 October 2005. C. S. Abdala, S. Quinteros, and C. Robles. Museo Ciencias Naturales, Salta, Argentina (MCN 2185–2187). Verified by S. Quinteros. Previously known from Quebrada de Randolfo, Antofagasta Department, Catamarca Province and from 2 km SE of Peña Fría, Antofagasta Department, Catamarca Province (Espinoza and Lobo 2003. Herpetologica 59:89–105). The present record extends the southwestern range 164 km from Quebrada de Randolfo and 151 km from the Peña Fría record (Espinoza and Lobo, *op. cit.*).

Submitted by **CRISTIAN ABDALA,** Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina (e-mail: popper@tucbbs.com.ar); and **FERNANDO LOBO**, Cátedra de Anatomía Comparada, Facultad de Ciencias Naturales, Universidad Nacional de Salta, Bolivia 5150, 4400, Salta, Argentina (e-mail: flobo@unsa.edu.ar).

OPHISAURUS VENTRALIS (Eastern Glass Lizard): USA: VIRGINIA: City of Virginia Beach: near Munden (36°34'46"N, 76°02'47"W, NAD 83), 14 May 1981. D. Jones. Verified by William M. Palmer (North Carolina State Museum of Natural History, NCSM 67451). Listed by the Virginia Department of Game and Inland Fisheries as state threatened based on its rarity in the southeastern corner of the Commonwealth. (Mitchell and Pague 1981. *In* K. Terwilliger [coord.], Virginia's Endangered Species, pp. 464–466. McDonald & Woodward Publ. Co., Blacksburg, Virginia). Previously known only from Back Bay National Wildlife Refuge and False Cape State Park on the eastern side of Back Bay (Mitchell and Pague, *op. cit.*, Mitchell 1994. The Reptiles of Virginia. Smithsonian Inst. Press, Washington, DC, 352 pp.; Mitchell and Reay 1999. Atlas of Amphibians and Reptiles in Virginia. Spec. Publ. 1, Virginia Dept. Game and Inland Fish, Richmond, Virginia, 122 pp.). The immature specimen represents the only known record west of Back Bay and is about 14 km WSW of the closest known site at False Cape Landing in False Cape State Park on the Currituck Spit. The record suggests that this state-listed species might have a broader distribution in southeastern Virginia than previously understood.

CALLOSELASMA RHODOSTOMA (Malayan Pit Viper). LAOS: KAMPHAENG NAKHON VIENTIANE (Vientiane Prefecture): 6 km N of Vientiane, in American housing compound. 15 June 1963. Louis G. Bush. AMNH R-90639. Verified by Bryan L. Stuart. Deuve (1970. Mem. ORSTOM. 39:239) reported this distinct species from the Xieng Khuoang (= Xiang Khoang) Plateau (Xiang Khoang Province), as well as Thakhek (= Khammouan) and Savannakhet Provinces in Laos, but without reference to specific locality or voucher information. Outside of Laos, this species is known from Thailand, the Malay Peninsula, the Greater Sunda Islands, Cambodia (Mondolkiri, Koh Khong, Kompong Som, Kampot Provinces), and the southern Vietnam provinces of Ninh Thuan, Binh Phuoc, Binh Duong, Ba Ria-Vung Tau, Tay Ninh, Dong Nai, and An Giang (Campden-Main 1969. A Field Guide to the Snakes of South Vietnam, p. 96; Smith 1943. The Fauna of British India, Ceylon and Burma, Including the Whole of the Indo–Chinese Region. Vol. III. Serpentes:498; Saint Girons 1972. Mém. Mus. Nat. Hist. Natur. n. s., A, Zool.:155; Stuart and Emmett 2006. Fieldiana: Zool., n.s., 109:23; Stuart et al. 2006. Raffles Bull. Zool. 54:152; Taylor 1965. Univ. Kansas Sci. Bull. 45:1060). Orlov et al. 2002. Faun. Abh. 23:200) also report this species from Kon Tum, Gia Lai, and Dak Lak Provinces of Vietnam, but without reference to specific locality or voucher information.

Submitted by **RAOUL H. BAIN**, Center for Biodiversity and Conservation, American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024, USA; and **NGUYEN QUANG TRUONG** and **DOAN VAN KIEN**, Department of Vertebrate Zoology, Institute of Ecology and Biological Resources, 18 Hoang Quoc Viet, Hanoi, Vietnam.

CHIRONIUS BICARINATUS (Two-keeled Whipsnake). URUGUAY: Dpto. Cerro Largo: Cañada Vichadero (32º07'43"S 53º43'48"W). 22 March 2002. F. Scarabino and E. Gonzalez. Colección de Reptiles, Museo Nacional de Historia Natural y Antropología, Montevideo (MNHN 6758, adult female). The range of this species includes Brazil from Salvador (Bahia) to Pelotas (Rio Grande do Sul) and some islands on the coast; southwest of Misiones and Rio Uruguay, Chaco, Corrientes, Salta, Formosa and Entre Ríos in Argentina; in Uruguay was reported from departments on the Rio Uruguay, Artigas, Salto and Rio Negro (Peters and Orejas Miranda 1970. Bull. U.S. Natl. Mus. 297: i-viii + 1–347; Dixon et al. 1993. Revision of the Neotropical snake genus *Chironius* Fitzinger [Serpentes, Colubridae]. Museo Regionale di Scienze Naturali, Torino, Monografía 13, 279 pp.; Carreira et al. 2005. Reptiles de Uruguay. DI.R.A.C. Facultad de Ciencias, Universidad de la República, Montevideo, 639 pp.). Carreira et al. (2005) cited the presence of this species on the east of Cerro Largo, but the locality was not confirmed because no voucher was collected. This specimen is the first for the east of Uruguay, and provides evidence for the continuous distribution of this species from Argentina to Brazil. The nearest locality is Pelotas, Rio Grande do Sul (31º45'25"N, 51º20'16"W), ca. 140 km distant. First departament record, and extends known distribution in Uruguay ca. 420 km from localities in Dpto. Rio Negro.

Submitted by **SANTIAGO CARREIRA** and **IGNACIO LOMBARDO**, Museo Nacional de Historia Natural y Antropología, 25 de Mayo 582, CP 11000, Montevideo, Uruguay (e-mail: carreira@fcien.edu.uy).

DENDRELAPHIS CAUDOLINEATUS (Stripe-tailed Bronzeback). MALAYSIA: JOHOR: Kampung Buau, W coast of Pulau Pemanggil (02°34.973'N, 104°18.868'E), 10 m elev. Collected at night, ca. 1 m above ground on a small tree. La Sierra University Herpetological Collection 8031. 21 August 2006. Female, SVL 853 mm, TL 339 mm. Perry Lee Wood, Jr. Verified by L. Lee Grismer. Previously known from Indonesia (Babi, Bangka, Batu Islands, Belitung, Kalimantan, Mentawai Archipelago, Nias, Riau Archipelago, Sumatra, and questionably from Java), Brunei Darussalam, Malaysia, Myanmar, and the Philippines (including Palawan and Sulu Tandjong) (David and Vogel 1996. The Snakes of Sumatra. An Annotated Checklist and Key with Natural History Notes. Edition Chimaira, Frankfurt am Main. 260 pp.). New record for Pulau Pemanggil (Grismer et al. 2006. Raffles Bull. Zool. 54[1]:173–196).

RODRIGUEZ**, Department of Biology, California State University, Northridge, Northridge, California 91330-8303, USA and Los Angeles Zoo, 5333 Zoo Drive, Los Angeles, California 90027, USA (e-mail: christopher.rodriguez.68@csun.edu); and **DAVID LAZCANO,** Universidad Autonoma de Nuevo Leon, Facultad de Ciencias Biológicas, Laboratorio de Herpetologia, Apartado Postal-513, San Nicolas de los Garza, Nuevo Leon, C.P.66450, México (e-mail: dvlazcano@hotmail.com).

GONIONOTOPHIS BRUSSAUXI (Mocquard's Lesser File Snake). CENTRAL AFRICAN REPUBLIC, Ngotto Forest, Baturi River area (03°54'N, 17°2'E; 445 m elev.), right bank of the Lobaye River. Within a mixed-species semi-deciduous primary rainforest at northern limit of the Guineo-Congolese rainforest. Between 25 November 1998 and 6 December 1999. P. Barrière. MNHN 2003.2959. Verified by Laurent Chirio. Subadult, SVL 222 mm, tail L 73 mm, found dead in a pitfall trap. First country record. Previously known from the forested areas of Cameroon, Equatorial Guinea, Gaboon, Republic of Congo, Democratic Republic of Congo, south through Angola, and east through Uganda. The unique Uganda specimen belongs to the eastern subspecies, *G. b. prigoginei* with higher ventral and subcaudal counts. Central African Republic reptiles have been subject of a recent publication (Chirio and Ineich 2006. Afr. J. Herpetol. 55[1]:23–59) dealing with a collection comprising about 5000 specimens deposited in MNHN; this species is unlisted in that collection.

Submitted by **IVAN INEICH**, Muséum national d'Histoire naturelle, Département de Systématique et Evolution, USM 602 Taxinomie et collections (Reptiles), 25 rue Cuvier, F–75005 Paris, France (e-mail: ineich@mnhn.fr); **THIERRY FRETEY**, Association Racine, 2 rue de la Cité, F–35360 Médréac, France (e-mail: fretey.thierry@wanadoo.fr); **MARC COLYN**, and **PATRICK BARRIÈRE**, Laboratoire Ecobio: Ecosystèmes, Biodiversité et Evolution, UMR 6553–CNRS, Université de Rennes 1, Station Biologique, F–35380 Paimpont, France (e-mail: Patrick.Barriere@laposte.net).

LAMPROPELTIS TRIANGULUM CELAENOPS (New Mexico Milksnake). USA: NEW MEXICO: Luna Co.: NM Hwy 27, 2.7 road miles N of Nutt (T20S, R6W, SE1/4 Sec 6), one male AOR. 07 September 2005. Bruce L. Christman, Michelle R. Cummer, and June M. Christman. Museum of Southwestern Biology (MSB 72462). Verified by J. Tomasz Giermakowski. First county record, first specimen documented from Nutt grasslands (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. of New Mexico Press, Albuquerque. xii + 431 pp.).

Submitted by **BRUCE L. CHRISTMAN**, **MICHELLE R. CUMMER,** and **JUNE M. CHRISTMAN,** 736 Cardenas SE, Albuquerque, New Mexico 87108, USA.

LAMPROPELTIS T. TRIANGULUM (Eastern Milksnake). USA: OHIO: Brown Co.: Union Township. South-facing hillside overlooking Ohio River along State Route 52 (38°45.526'N, 83°51.658'W). 13 June 2006. LYCODON LAOENSIS (Indo-chinese Wolf Snake). LAOS: KAMPHAENG NAKHON VIENTIANE (Vientiane Prefecture): vicinity of Vientiane. January 1963. Louis G. Bush. Verified by Bryan L. Stuart. AMNH R-94153–94154. This is a new provincial record for Laos. Dueve (1970. Mem. ORSTOM. 39:124) states that this species is also known from all of the provinces in central and southern Laos, but without localities or voucher information. This species is also known from India, the Malay Peninsula, Thailand, China (Yunnan Province), Cambodia (Kompong Som, Siem Reap Provinces), and Vietnam (Quang Nam, Lam Dong, and Dong Nai Provinces, as well as Ho Chi Minh City) (Campden-Main 1969. A Field Guide to the Snakes of South Vietnam, p. 34; Saint Girons 1972. Mém. Mus. Nat. Hist. Natur. new ser. A, Zool.:56; Smith 1943. The Fauna of British India, Ceylon and Burma, including the Whole of the Indo–Chinese Region. Vol. III. Serpentes, p. 260; Taylor 1965. Univ. Kansas Sci. Bull. 45:740–748; Zhao and Adler 1993. Herpetology of China. Society for the Study of Amphibians and Reptiles, Contributions to Herpetology, No. 10, p. 246). In Vietnam, it has also been reported from Bac Giang, Song Be (= Binh Phuoc), and Tay Ninh Provinces, but without reference to specific locality or voucher information (Nguyen et al. 2005. Checklist of Reptiles and Amphibians of Vietnam, p. 88; Pham et al. 2000. J. Biol. 22:24–29).

Submitted by **RAOUL H. NERODIA SIPEDON (Northern Watersnake). USA: ILLINOIS: Hamilton Co.: Hamilton County State Fish and Wildlife Area (38°03'56"N, 88°23'52"W). 15 April 2006. Cy L. Mott and Michael A. Steffen. Verified by Ronald A. Brandon. Color photo voucher. SIUC R-03446. Juvenile specimen. New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. xii + 282 pp.).

Submitted by **CY L. MOTT**, Cooperative Wildlife Research Laboratory, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA; e-mail: cm8755@siu.edu.

OPHEODRYS AESTIVUS (Rough Greensnake). USA: ARKANSAS: VAN BUREN CO.: near Brock Creek Lake: 35.49037°N, 92.80132°W. 15 Oct. 2005. Josh Engelbert, Melissa Patrick, Ashley Patrick, and Mauricio Solis. Verified by Stanley E. Trauth. Voucher specimen in Arkansas State University Museum of Zoology (ASUMZ 29441). County record (Trauth et al., 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville, 421 pp.).

Submitted by **JOSH ENGELBERT, MELISSA PATRICK,** and **MAURICIO SOLIS,** Department of Biological Sciences, Arkansas State University, P.O. Box 599, State University, Arkansas 72467-0599, USA (e-mail: josh.engelbert@smail.astate.edu).

OPHEODRYS AESTIVUS (Rough Greensnake). USA: ILLINOIS: CLAY CO.: Snake was found DOR at 1.8 km S of Effingham County line on IL Rt. 37 (38.8997°N, –88.6892°W). 16 September 2006. Specimen collected by John K. Tucker and Maelin J. Abbott, Illinois Natural History Survey. INHS 20134. Verified by Chris Phillips. Specimen is a first county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. xii + 282 pp.).

Submitted by **JAMES T. LAMER, JOHN K. TUCKER, CHAD R. DOLAN,** and **MAELIN J. ABBOTT**, Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

OXYRHOPUS MELANOGENYS (Black-headed Calico Snake). GUYANA: Mazaruni-Potaro District, Wokomung Massif (04°55'34"N, 59°55'24"W), ~1077 m elev. 05 December 2006. Collected by D. Bruce Means and Michelle Kalamandeen. Verified from photographs by William W. Lamar. Specimen preserved in 95% ethanol and deposited in Centre for the Study of Biological Diversity, University of Guyana Museum (HR-700), plus four photographs deposited in the Florida Museum of Natural History (UF-150161). Found crawling through wet leaf litter on top of a log and a few moments later, partially under a rock loosely embedded in dry overflow sediments of a rocky mountain stream. First record of species in Guyana and extends range about 640 km ESE of the closest known locality in French Guiana (Hollowell and Reynolds [eds.] 2005. Checklist of the Terrestrial Vertebrates of the Guiana Shield. Bull. Biol. Soc. Washington 13:1–109; Starace 1998. Guide des Serpents et Amphisbenes de Guyane. Ibis Rouge Editions, Guadaloupe, Guyane). The record is notable because it fills a distributional gap between French Guiana (Guyane) on the east and Venezuela on the west.

Submitted by **D. BRUCE MEANS**, Coastal Plains Institute and Land Conservancy, 1313 Milton Street, Tallahassee, Florida 32303, USA; and **MICHELLE KALAMANDEEN**, Centre for the Study of Biological Diversity, Department of Biology, University of Guyana, Turkeyen Campus, East Coast Demerara, Guyana.

PROTOBOTHROPS MUCROSQUAMATUS (Brown-spotted Pitviper). VIETNAM: LANG SON PROVINCE: CAO LOC DISTRICT: Mau Son Commune: Mau Son Mountain: IEBR 2492, nr. 21°52.012'N, 106°57.947'E, 380 m elev., ca. 200 km SE Ha Giang Province (Ziegler et al. 2006. Sauria, Berlin 28[1]:29–40). 14 October 2006. T. Q. Nguyen, K. V. Doan, and C. T. Ho. Verified by Nikolai L. Orlov. Previously recorded from Lao Cai, Ha Giang, Cao Bang, Bac Kan, Thai Nguyen, Vinh Phuc, Quang Ninh, Hai Phong, Hai Duong, Ha Tay, Ninh Binh, Nghe An, Ha Tinh, Quang Tri, Kon Tum, Gia Lai, and Thua Thien-Hue provinces; extralimitally, India, Bangladesh, China (including Hainan), Taiwan, and Myanmar (Bain et al. 2007. Herpetol. Rev. 38:107–117; Darevsky 1999. *In* H. Submitted by **NGUYEN QUANG TRUONG**, **DOAN VAN KIEN, HO THU CUC**, and **NGUYEN VAN SANG**, Institute of Ecology and Biological Resources, 18 Hoang Quoc Viet, Hanoi, Vietnam (e-mail: truong@iebr.vast.ac.vn).

SISTRURUS CATENATUS TERGEMINUS (Western Massasauga). USA: OKLAHOMA: WASHINGTON CO.: 1.3 km N of East Tuxedo Blvd on Bison Rd. (N 3990): 15S 241225, 4073104 (UTM WGS84). 14 September 2004. Josh Engelbert and Melissa Patrick. Verified by Stanley E. Trauth. Voucher specimen in Arkansas State University Museum of Zoology (ASUMZ 29859). New county record (Webb 1970. Reptiles of Oklahoma. University of Oklahoma Press, Norman, 370 pp.; and Distribution of Oklahoma Amphibians and Reptiles by Recorded Sighting, http://www.biosurvey.ou.edu/dokadesc.html.

Submitted by **JOSH ENGELBERT** and **MELISSA PATRICK**, Department of Biological Sciences, Arkansas State University, P.O. Box 599, State University, Arkansas 72467-0599, USA (e-mail: josh.engelbert@smail.astate.edu).

SONORA SEMIANNULATA (Groundsnake). USA: NEVADA: PERSHING CO.: Sonoma Range, above Sonoma Creek (40°48'49.0"N, 117°42'29.8"W, 1505 m elev.) under a small rock in sagebrush habitat. 07 May 2006. Bryan Hamilton. Verified by Jack Sites (BYU 8591). Three individuals of this species were observed at this locality in 1993 but no vouchers were collected (Scott, pers. comm.). This record fills a gap in the northeastern distribution of this species with the nearest documented records 64 km E (Battle Mountain, Humboldt Co., Nevada; CAS-SUR 10032), 160 km NW (Denio, Pershing Co., Nevada; Stebbins 2003. Western Reptiles and Amphibians. 3rd ed., Houghton Mifflin Company, Boston, Massachusetts), and 60 km SW (Humboldt House, Pershing Co., Nevada; UNR 493).

Submitted by **BRYAN HAMILTON,** 100 Great Basin National Park, Baker, Nevada 89311, USA; and **PAULETTE CONRAD,** Nevada Department of Wildlife, 4747 Vegas Drive, Las Vegas, Nevada 89108, USA (e-mail: pconrad@ndow.org).

STORERIA DEKAYI (Dekay's Brownsnake). USA: ARKANSAS: LONOKE CO.: 2.2 km E. Ward (T5N, R9W, S25). 10 April 2005. Donald F. McKenzie. Verified by Stanley E. Trauth. Arkansas State University Museum of Zoology Herpetological Collection (ASUMZ 29316). New county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **MICHAEL V. PLUMMER**, Department of Biology, Box 12251, Harding University, Searcy, Arkansas 72149, USA (e-mail: plummer@harding.edu); and **DONALD F. MCKENZIE,** Wildlife Management Institute, 2396 Cocklebur Road, Ward, Arkansas 72176, USA (e-mail: wmidm@ipa.net).

STORERIA OCCIPITOMACULATA (Northern Red-bellied Snake). USA: SOUTH DAKOTA: MARSHALL CO.: BIA Hwy 15, 4.8 km S Veblin. 26 September 2005. Lars Bryan Williams. Verified by Zannita Fast Horse. Campbell Museum, Clemson University (CUSC 2323–24). Two snakes found crossing road near wetland. County record (Ballinger et al. 2000. Trans. Nebraska Acad. Sci. 26:29–46). Extends distribution ca. 46 km NW from populations in adjacent Roberts Co.

Between 1997 and 2005, increased survey effort and closer examination of natural history collections have resulted in the description of 53 new species of amphibians and 27 new species of reptiles from Indochina (Laos, Cambodia, and Vietnam). Over that same time period, range extensions into Indochina of 36 amphibian species and 33 reptile species were recorded. Despite this increase in knowledge, the diversity of the region remains imperfectly known, as new discoveries continue to be published at a rapid pace; in 2006 (up until mid-November) six species of amphibians, one species of snake, and one species of lizard were described from the region, along with 37 new country or provincial records (Bain and Stuart 2006 [2005]; Bain et al. 2006; Ohler and Delorme 2006; Orlov, Ananjeva, and Ho 2006; Orlov, Dutta et al. 2006; Orlov, Nguyen, and Nguyen 2006; Stuart 2006; Stuart and Emmett 2006; Stuart et al. 2006; Ziegler and Le 2006; Ziegler, Ohler et al. 2006; Ziegler, Thanh et al. 2006). Herein, we provide one novel country record and 60 novel provincial records for Vietnam. We feel that specific locality and voucher data is crucial to understanding patterns of diversity, so we include species that have been reported in the literature, but without reference to specific locality or voucher material. We comment on those records that have been reported on in only a general way, and we provide novel natural history information for recently described species that are very poorly known. Our taxonomy follows Frost et al. (2006), Malhotra and Thorpe (2004), Schmitz et al. (2004), and Utiger et al. (2002). Referred specimens are housed either at the Institute of Ecology and Biological Resources, Hanoi (IEBR), or the American Museum of Natural History, New York (AMNH). Specimens on long term custodial loan from IEBR to AMNH are assigned dual catalogue numbers (e.g., AMNH XXXX/IEBR YYYY).

AMPHIBIA

ORDER ANURA

FAMILY BUFONIDAE

Ingerophrynus macrotis. THUA THIEN-HUE PROVINCE, A Luoi District, Huong Nguyen Commune: IEBR 2303, 16°14.529'N, 107°27.354'E, elev. ~ 150 m, 17 August 2005, R. H. Bain, T. Q. Nguyen, and A. X. Tran. A Roang Commune: AMNH A-169338, nr. 16°04.636'N, 107°29.290'E, elev. ~ 650 m, 26 August 2005, R. H. Bain, T. Q. Nguyen, and V. S. Ho; from undergrowth on a bank, of a rocky stream in primary forest . *Ingerophrynus macrotis* is a widespread species (Myanmar, Thailand, Laos, and Cambodia), but in Vietnam voucher specimens have only been reported from Dak Lak Province (Buon Geng District [= Buon Giang Lanh]) (Bourret 1942; Inger et al. 1999; Nguyen and Hoang 2000; Ohler et al. 2002; Smith 1930; Stuart 2005b; Taylor 1962).

FAMILY MICROHYLIDAE

Microhyla marmorata. THUA THIEN-HUE PROVINCE, A Luoi District, A Roang Commune: AMNH A-169291, nr. 16°04.636'N, 107°29.290'E, elevation ~ 650 m, 29 August 2005, R. H. Bain and T. Q. Nguyen; AMNH A-169292, elevation ~ 680 m, 30 August 2005, R. H. Bain, T. Q. Nguyen, and V. S. Ho. Both specimens were collected along leaf litter around forest ponds. Dozens of males were calling in and around the pond: floating on the surface, atop herbaceous undergrowth (< 5 cm from the ground), atop fallen logs, and from the leaf litter. In life the oblique shape on the dorsum and head is green-grey, outlined with white; spots along the dorsum, legs, and flanks are black, outlined in white; white lines run along the dorsum and legs; limbs pinkish with brown bands; the remainder of the dorsum mottled yellow; venter brown, mottled with yellow on chest and belly. This species is known from Ha Tinh (Huong Son, Ky Anh- Ke Go Districts), Quang Binh (Phong Nha District), and Quang Nam (Tra My District) Provinces in Vietnam, as well as Khammouan and Bolikhamxay Provinces in Laos (Bain and Nguyen 2004a).

FAMILY MEGOPHRYIDAE

Brachytarsophrys feae. LAO CAI PROVINCE, Van Ban District, Nam Tha Commune, forest above Nam Tha River: AMNH A-168658, nr. 21°55'13" N, 104°22'15" E, elevation 950 m, 7 Sep-

tember 2004, R. H. Bain. AMNH A-168659, 168660, 21°54'56"N, 104°21' 39" E, elevation 1300–1400 m, 11–12 September 2004, R. H. Bain, T. Q. Nguyen, K. V. Doan, A. C. Lu, and V. T. Trieu. AMNH A-168658 was collected from a pitfall trap set in mixed hardwood and bamboo forest between two tributaries of the Nam Tha. AMNH A-168659, 660 were collected under leaves on the forest floor, > 20 m from a small stream. Within Vietnam, this species has been reported from Lang Son (Mao Son [= Mau Son]), and Vinh Phuc (Tam Dao N.P.) (Bourret 1942; Inger et al. 1999). Orlov et al. (2002) include 'northern Vietnam' in the distribution, Nguyen, Ho, and Nguyen (2005) note this species from Lao Cai Province, and Ho et al. (2005) note this from Cao Bang (Nguyen Binh District), but without reference to precise locality or voucher specimens. It is otherwise known from Myanmar, Thailand, and China (Yunnan Province) (Bourret 1942; Fei et al. 2005; Taylor 1962).

Leptobrachium banae. THUA THIEN-HUE PROVINCE, A Luoi District, A Roang Commune: AMNH A-169283, 16°04.877'N, 107°28.424'E, elevation ~ 850–900 m, 28 August 2005, R. H. Bain, T. Q. Nguyen, and V. S. Ho; collected from the bank of a cascading, rocky stream, a few meters from the water. IEBR 2304 nr. 16°04.636'N, 107°29.290'E, elevation ~ 650 m, 29 August 2005, R. H. Bain and T. Q. Nguyen; on the stream bank. Color in life as in holotype with the following exceptions: limb bands and flank spots orange; venter grey, spotted with white on throat and thighs, marbled with white on chest and belly. Within Vietnam, this species is only known from its type locality in Gia Lai Province (An Khe District [= K Bang]) (Lathrop et al. 1998). Nguyen, Ho, and Nguyen (2005) note this from Quang Nam Province, but without reference to voucher specimens or specific locality. This species has also been reported from Xe Kong Province, Laos (Stuart 2005b).

Leptolalax pluvialis. HA GIANG PROVINCE, Vi Xuyen District, Cao Bo Commune, Mount Tay Con Linh II: AMNH A-163833–163834, 22°46'18"N, 104°49'12"E, elevation 1710 m, 10 September 2000, C. Johnston; from a small pan trap set in the forest floor. They were erroneously reported as juveniles of *L. bourreti* (Bain and Nguyen 2004b), but subsequent analysis showed that these were adults of *L. pluvialis*. This is the first record of this species east of the Red River. It is otherwise only known from the type locality on Mt. Fan Si Pan, Lao Cai Province (Ohler et al. 2000).

Leptolalax sungi. LAO CAI PROVINCE, Van Ban District, Nam Tha Commune, tributary to Khe Pan River: AMNH A-168676–168677, 21°56'39"N, 104°24'12"E, elevation 331 m, 17 September 2004, R. H. Bain, K. V. Doan, and V. T. Trieu. AMNH A-168676 was collected on an embankment ~ 5 m from the stream's edge atop an herbaceous leaf (~ 2 m off the ground), and AMNH A- 168677 was collected on the ground of a flat, rocky stream bank, ~ 1.5 m from the edge of the water. These specimens have distinct day and night coloration. At night, the dorsum is a solid red-brown with creamy yellow tubercles towards the sacrum; flank yellow, with some black speckling; limbs banded with light brown; canthus and supratympanic fold each creamy yellow above, with thick dark brown line below; loreal red-brown, with two dark spots, upper lip with three dark spots. In the day, the color is the same except that the dorsum is creamy with irregular brown splotches; a black loreal spot extends above canthus; dorsal tubercles red-brown; finger tips white. This species is otherwise known only from the type locality of Vinh Phuc Province (Tam Dao N.P.) (Lathrop et al. 1998). This is the first record of it west of the Red River. Nguyen, Ho, and Nguyen (2005) note this species from Van Yen District, Yen Bai Province, but without reference to precise locality or voucher specimens.

Leptolalax tuberosus. THUA THIEN-HUE PROVINCE, A Luoi District, A Roang Commune: AMNH A-169283, 16°04.877'N, 107°28.424'E, elevation ~ 850–900 m, 28 August 2005, R. H. Bain, T. Q. Nguyen, and V. S. Ho. Calling from atop a shrub on a steep bank, ~ 1 m above the ground, 5 m from the edge of a cascading, rocky stream in disturbed primary forest. In life, dorsum sandy with green hatching pattern; brown spots on upper lip and posterior portion of tympanum; limbs with olive green bands; iris sandy-gold, upper one-quarter peach, with thick network of deep indigo. This species is only known from two other provinces in Vietnam, Gia Lai (An Khe District [= K Bang]) and Quang Nam (Tra My District) (Bain and Nguyen 2002a; Inger et al. 1999).

Ophryophryne gerti. THUA THIEN-HUE PROVINCE, A Luoi District, A Roang Commune, A Pat Stream, above Ho Chi Minh Highway marker kilometer 398 + 700: AMNH A-169287, nr. 16°04.636'N, 107°29.290'E, elevation ~ 680 m, 30 August 2005, R. H. Bain, T. Q. Nguyen, and V. S. Ho. This was collected sitting on a leaf atop a small shrub (< 1 m), beside a rocky-bottomed stream. QUANG NAM PROVINCE, Tra My District, Tra Don Commune: AMNH A-163668, nr. 15°11.688'N, 108°02.413'E, elevation 980 m, 17 March 1999, T. Q. Nguyen. In life, dorsum brown, butterfly markings and irregular patterns darker brown, outlined in tan; dorsal ridges, including supratympanic fold, outlined in tan; loreal, upper lip, tympanic regions, and anterior portion of upper arm dark brown, continuing as a sash on forearm; front of knee, leg bands dark brown; flank tan, with anterior grey wash; flank tubercles black below, tan above; iris orange-brown. In Vietnam, this species is otherwise only known from Gia Lai (An Khe District [= K Bang]) and Lam Dong (Cam Li, Dran) Provinces (Ohler 2003). It has also been reported from Champasak Province, Laos (Stuart 2005b).

Ophryophryne hansi. THUA THIEN-HUE PROVINCE, Huong Thuy District, Khe Dau, Duong Hoa Commune, tributary to Dau River: AMNH A-169286, nr. 16°17.995'N, 107°33.307'E, elevation ~ 109 m, 8 September 2005, R. H. Bain, T. Q. Nguyen, C. K. Dang, and T. D. Nguyen; in leaf litter, a few meters from edge of a stream. A Luoi District: Huong Nguyen Commune, Vu Vu Stream: AMNH A-169284, 16°14'30"N, 107°29'23"E, elevation ~ 100 m, 20 August 2005, R. H. Bain, T. Q. Nguyen, and M. V. An. In Vietnam, this species is also known from Quang Binh Province (Phong Nha-Ke Bang), Quang Nam Province (Tra My District) and Gia Lai Province (An Khe District [= K Bang]) (Frost et al. 2006; Ohler 2003; Ziegler, Ohler et al. 2006). The specimen reported by Frost et al. (2006), AMNH A-163669 from Quang Nam, has dorsum dark brown, with irregular light brown markings; limbs with light brown markings forming bands; dorsal tubercles either red-brown or tan; iris grey-brown. This species has also been reported from Laos (Bolikhamxay, Khammouan, and Xe Kong Provinces), and Cambodia (Stung Treng Province) (Stuart 2005b; Stuart et al. 2006).

Ophryophryne microstoma. THUA THIEN-HUE PROVINCE, A Luoi District, A Roang Commune: AMNH A-169285, nr. 16°04.636'N, 107°29.290'E, elevation ~ 680 m, 23 August 2005, R. H. Bain, T. Q. Nguyen, and V. S. Ho. LAO CAI PROVINCE, Van Ban District, Nam Tha Commune, tributary to Khe Pan River: AMNH A-168682, 21°56'39"N, 104°24'12"E, elevation 331 m, 17 September 2004, R. H. Bain, K. V. Doan, and V. T. Trieu. In Vietnam, this species is also known from a wide latitudinal range of provinces: Ha Giang (Yen Minh District), Cao Bang (Nguyen Binh), Lang Son (Mao Son [= Mau Son]), Vinh Phuc (Tam Dao N.P.), and Gia Lai (An Khe District = [K Bang]) (Bain and Nguyen 2004b; Inger et al. 1999; Ohler 2003). This species has also been reported from Thua Thien-Hue (A Luoi), Lao Cai (Van Ban), Hai Duong (Chi Linh), Thanh Hoa (Ben En), Quang Tri (Dong Tam Ve), but without reference to specific locality data or voucher information (Ho et al. 2001; Ho et al. 2005; Nguyen, Ho, and Nguyen 2005; Nguyen, Nguyen, and Ho 2005). It is otherwise known from Thailand and Yunnan Province, China (Fei et al. 2005; Ohler 2003).

Ophryophryne pachyproctus. HA TINH PROVINCE, Huong Son District, Rao An region, tributaries of Rao An River: AMNH A-161358, 18°21'53"N, 105°13'13"E, elevation 200 m, 12 May 1998, D. A. Kizirian, and T. Q. Nguyen. In Vietnam, this species has been reported from two provinces, Vinh Phuc (Tam Dao N.P.) and Nghe An (Inger et al. 1999; Ohler 2003). Nguyen, Ho, and Nguyen (2005) report this from Huong Son District and other provinces, but without reference to specific locality data or voucher information. It is otherwise known from Yunnan Province, China (Fei et al. 2005; Ohler 2003).

Family Dicroglossidae

Limnonectes hascheanus. THUA THIEN-HUE PROVINCE, A Luoi District, A Roang Commune: AMNH A-169294, nr. 16°04.285'N, 107°29.499'E, elevation ~ 680–820 m, 27 August 2005, R. H. Bain, T. Q. Nguyen, and V. S. Ho; calling from a mud burrow, about 3 m from low-flowing water. This specimen was one of several males of this species calling alongside the stream. NGHE AN PROVINCE, Con Cuong District, Chau Khe Commune, Hieng Stream: AMNH A-161224, 19°2'17"N 104°42'6"E, elevation 300 m, 29 April 1998, T. Q. Nguyen. LAM DONG PROVINCE, Da Teh District, Quoc Oai Commune: IEBR 1263, nr. 11°41.010'N, 107°32.032'E, elevation 630 m, 6 May 2003, T. Q. Nguyen. This specimen was collected from a small puddle on a logging road. In Vietnam, this species has been reported from Lao Cai (Thai Nien) and Quang Binh (Phong Nha District) Provinces (Bourret1942; Ziegler 2002; Ziegler et al. 2004). This species has also been reported from Ha Tinh (Khe Tho-Ke Do), Quang Tri (Dak Rong, Huong Hoa), and Dong Nai (Cat Tien) Provinces, as well as from 'central and northern regions of Annam mountains,' but without specific locality or voucher information (Le 2005; Nguyen and Ho 2002; Orlov et al. 2002). This is a widespread species across continental southeast Asia and the Greater Sunda islands (Smith 1930).

Limnonectes poilani. THUA THIEN-HUE PROVINCE, A Luoi District, Huong Nguyen Commune, Da Stream: AMNH A-169295, 16°15.625'N 107°26.634'E, elevation ~ 160 m, 16 August 2005, R. H. Bain, Q. T. Nguyen, and X. A. Tran; collected in the mud of a slow-moving portion of the stream surrounded by secondary forest. A Lieng Stream: AMNH A-169296, 16°14.185'N 107°27.669'E, elevation ~ 160 m, 17 August 2005, R. H. Bain, T. Q. Nguyen, and A. X. Tran. A Bong stream: AMNH A-169297, 16°14.285'N, 107°27.177'E, elevation, ~ 150 m, 19 August 2005, R. H. Bain, T. Q. Nguyen, and A. X. Tran. LAM DONG PROVINCE, Da Teh District, Quoc Oai Commune: IEBR 1261, nr. 11°41.010'N, 107°32.032'E, elevation 630 m, 5 May 2003, T. Q. Nguyen. This was described from Quang Tri Province (Dong Tam–Ve), and has been reported from Quang Nam Province (Tra My District), Quang Binh Province (Minh Hoa), and (as *L.* cf. *blythii*) Gia Lai Province (An Khe District [= K Bang]) (Bourret 1942; Frost et al. 2006; Inger et al. 1999; Ngo et al., 2006; Ziegler, Ohler et al. 2006). This species has been reported from A Luoi District, and Cat Tien N.P., Dong Nai Province (both as *L. blythii*), but without exact locality or voucher information (Ho 2002b; Nguyen and Ho 2002; Nguyen, Ho, and Nguyen 2005). This species is also known from Mondolkiri Province, Cambodia (Stuart et al. 2006).

Occidozyga martensii. THUA THIEN-HUE PROVINCE, A Luoi District, Huong Nguyen Commune: AMNH A-16928, 16°14.529'N, 107°27.354'E, elevation, ~ 150 m, 17 August 2005, R. H. Bain, T. Q. Nguyen, and A. X. Tran; floating in amplexus, in a large buffalo wallow. This species is also reported from Ha Tinh (Huong Son District), Quang Binh (Phong Nha District), Dac Lak (Yok Don), Gia Lai (An Khe District), and Ba Ria-Vung Tau (Con Dao) Provinces (Frost et al. 2006; Inger et al. 1999; Ngo et al. 2006; Smith 1920; Ziegler 2002; Ziegler et al. 2004). It has also been reported from Lao Cai (Van Ban), Son La (Sop Cop, Xuan Nha), Thanh Hoa (Ben En), Nghe An (Pu Mat, Pu Huong) Quang Nam (Phuoc Son), Thua Thien-Hue (A Luoi), Dong Nai (Cat Tien), but without reference to locality or voucher specimens (Le and Hoang 2001; Le and Nguyen 1999; Ho 2002b; Hoang et al. 2005; Nguyen 2005; Nguyen, Nguyen, and Ho 2005; Nguyen and Ho 2002; Nguyen and Hoang 2000). It is also known from Thailand, Laos (Champasak, Vientiane, Bolikhamxay, and Attapeu Provinces), China (Yunnan, Hainan, and Guangxi Provinces), and the Cardamom Mountains of Cambodia (Fei et al 2005; Ohler et al. 2002; Stuart 2005b; Taylor 1962; Teynie et al. 2004).

Family Ranidae

Amolops cremnobatus. QUANG BINH PROVINCE, Minh Hoa District, Cha Lo: AMNH A-161141, 14 April 1998, D. A. Kizirian, and T. Q. Nguyen. This species has previously been reported from neighboring Ha Tinh Province (Huong Son District) and Nghe An Province (Con Cuong District) (Bain and Nguyen 2001; Chen et al. 2005). Outside of Vietnam, this species is known from Vientiane Municipality, and Khammouan and Bolikhamxay Provinces of Laos (Inger and Kottelat 1998; Stuart 2005b).

Huia absita. THUA THIEN-HUE PROVINCE, A Luoi District, A Roang Commune, A Pat Stream, above Ho Chi Minh Highway marker kilometer 398 + 700: AMNH A-169302, 16°4'28"N, 107°29'14"E, elevation ~ 653 m, 23 August 2005, R. H. Bain, T. Q. Nguyen, V. S. Ho, and V. T. Le; alongside a stream in a patch of grass. KON TUM PROVINCE, Kon Plong District, Mang But Commune, nr. Vi Xay Village, Nuoc Re Stream: IEBR 307, 315, 316, 14°45.665'N, 108°15.245'E, elevation 1120–1200 m, 3–4 January 2001, T. Q. Nguyen. Mang Canh Commune, Nuoc Ka

Stream: IEBR 337, 14°41.950'N, 108°12.095'E, elevation 1100–1200 m, 10 January 2001, T. Q. Nguyen. The Kon Tum specimens were all collected in small streams in mixed evergreen-bamboo forest in humid weather. This species is currently only known from Quang Nam Province (Tra My District), Vietnam (Bain and Nguyen 2005), and Xe Kong and Saravane Provinces, Laos (Stuart and Chan-ard 2005). Orlov, Ananjeva, and Ho (2006) described a new species of cascade ranid, *Rana gigatympana*, from Kon Tum Province (Kon Plong District), which looks remarkably like *Huia absita*, although it exhibits a much larger tympanum (male tympanum diameter: eye diameter 1.14–1.31 for *R. gigatympana*, 0.60–0.89 for *H. absita*). The tympanum diameter of our specimens from Kon Plong (all males), however, fell well within the range of *Huia absita* (tympanum diameter: eye diameter 0.69–0.92).

Huia bacboensis. LAO CAI PROVINCE, Van Ban District, Nam Tha Commune, tributary to Khe Pan River: AMNH A-168739, 21°56'24"N, 104°24'7"E, elevation 360–400 m, 15 September 2004, R. H. Bain, K. V. Doan, and V. T. Trieu. This species is otherwise known from the following provinces: Tuyen Quang (Na Hang Nature Reserve), Bac Kan (Ba Be National Park), and Nghe An (Con Cuong) (Bain et al. 2003).

Huia banaorum. HA TINH PROVINCE, Huong Son District, Huong Son Reserve, Rao An region: AMNH A-161249–161250, 18°22'N, 105°13'E, elevation 200 m, 20 April 1998, T. Q. Nguyen. This species has otherwise only been reported from An Khe District (= K Bang), Gia Lai Province in Vietnam (Bain et al. 2003), and from Mondolkiri, Stung Treng, and Ratanakiri Provinces of eastern Cambodia (Stuart et al. 2006). Nguyen, Ho, and Nguyen (2005) report this species from Danang (Ba Na N.P.), but without reference to specific locality or voucher information.

Huia khalam. KON TUM PROVINCE, Kon Plong District, Mang But Commune: IEBR 231, 250, 251, 268–270, 286, 288, 312. 14°45.657'N, 108°15.835'E, elevation 1400–1540 m, 28 December 2000–4 January 2001, T. Q. Nguyen. This species has only been reported from Thua Thien-Hue (Bach Ma N. P.) and Da Nang (Ba Na N. P.) Provinces in Vietnam, and Xe Kong (Kaleum District) and Saravane (Samoy District) Provinces in Laos (Stuart et al. 2005).

Huia morafkai. THUE THIEN-HUE PROVINCE, A Luoi District, Huong Nguyen Commune, A Lieng Stream: AMNH A-169309, 16°14'11"N, 107°27'40" E, elevation ~ 160 m, 17 August 2005, R. H. Bain, T. Q. Nguyen, and A. X. Tran; from a branch ~ 4 m off the ground, ~ 3 m from the side of the stream. AMNH A-169311–169312: A Roang Commune, forested stream at Ho Chi Minh Highway marker kilometer 398+700, 16°4'28"N 107°29'14" E, elevation ~ 653 m, 26 August 2005, R. H. Bain, N.Q. Nguyen, and V. S. Ho; from rocky cascades. AMNH A-169313: 16°4'53"N, 107°28'25"E, elevation ~ 850–900 m, 28 August 2005, R. H. Bain, N.Q. Nguyen, and V. S. Ho; from rocky cascades. In Vietnam, this species has previously been reported from the following provinces: Ha Tinh (Huong Son District), Quang Nam (Tra My District), and Gia Lai (An Khe District [= K Bang]), (Bain et al. 2003; Bain and Stuart 2006 [2005]). It is otherwise known from Champasak and Xe Kong Provinces in Laos, and Ratanakiri and Mondolkiri Provinces of Cambodia (Bain and Stuart 2006 [2005]; Stuart et al. 2006; Teynie et al. 2004).

Huia orba. THUA THIEN-HUE PROVINCE, A Luoi District, A Roang Commune, stream at Ho Chi Minh Highway marker kilometer 398 + 700: AMNH A-169314, 16°4'28"N, 107°29'14"E, elevation ~ 653 m, 23 August 2005, R. H. Bain, T. Q. Nguyen, V. S. Ho, and T. V. Le; atop a small fern (< 1 m off the ground), ~ 3 m from the bank of a swift, rocky bottomed stream. This species is otherwise only known from Ha Tinh Province (Huong Son District) in Vietnam, and eastern portions of Khammouan and Bolikhamxay Provinces of Laos (Stuart and Bain 2005).

Sylvirana attigua. THUE THIEN-HUE PROVINCE, A Luoi District, Huong Nguyen Commune: AMNH A-169303, nr. 16°14'26"N, 107°27'11"E, elevation ~152 m, 19 August 2005, R. H. Bain, T. Q. Nguyen, and V. M. Tran; from a small branch above a small, still, streamside pool. Vu Vu Stream: AMNH A-169304, 16°14'30"N, 107°29'23"E, 20 August 2005, R. H. Bain, T. Q. Nguyen, and M. V. Tran. A Roang Commune, stream at Ho Chi Minh Highway marker kilometer 398 + 700: AMNH A-169305, nr. 16°4'28"N, 107°29'14"E, elevation ~ 653 m, 26 August 2005, R. H. Bain, T. Q. Nguyen, and V. S. Ho; on a leaf about 0.5 m above the ground, 2 m from the stream. Nam Dong District, Thuong Lo Commune, tributary to Cha May River: AMNH A-169306, 16°7'40"N, 107°44'44"E, elevation 220–270 m, 2 September 2005, R. H. Bain, T. Q. Nguyen, and V.P. Nguyen; collected atop a small stick over a tiny pool of water in the forest. This species has been reported from Quang Nam (Tra My District), and Gia Lai (An Khe District [= K Bang]) Provinces (Bain and Nguyen 2002b; Inger et al. 1999). This species has been reported from Thua Thien-Hue Province and Kon Tum Province (Ngoc Linh Mountain, and Kon Plong District), but without precise locality data or voucher specimen information (Nguyen 2002; Nguyen, Ho, and Nguyen 2005). It is otherwise known from Champasak and Xe Kong Provinces in Laos and Mondolkiri Province in Cambodia (Stuart 2005b; Stuart et al. 2006).

Sylvirana maosonensis. BAC KAN PROVINCE, Ba Be Lake National Park, ca. 1 km W on trail into forest from shoreline on west end of Lake: AMNH A-161488, 8 August 1997, D. R. Frost, and C. J. Raxworthy. In Vietnam, this species is known from the following provinces Ha Giang (Vi Xuyen District), Lang Son (Mau Son), Vinh Phuc (Tam Dao N.P.), Ha Tinh (Khe Tho- Ke Do), and Quang Binh (Minh Hoa) (Bain and Nguyen 2004b; Bourret 1942; Inger et al. 1999; Ziegler 2002; Ziegler, Ohler et al. 2006). This species has been reported from other northeastern provinces of Vietnam, but without reference to specific localities or voucher specimens (Ho et al. 2001; Ho et al. 2005; Nguyen 2005; Nguyen et al. 2000; Nguyen, Ho, and Nguyen 2005; Orlov et al. 2002). This species has also been reported from Bolikhamxay and Khammouan Provinces of Laos (Stuart 2005b).

Family Rhacophoridae

Chiromantis vittatus. THUA THIEN HUE PROVINCE, A Luoi District, Huong Nguyen Commune: A169316, 169317, 169337, 16°14'32"N, 107°27'21"E, 17 August 2005, R. H. Bain, T. Q. Nguyen, and A. X. Tran; in amplexus on a branch above a buffalo wallow. The green eggs were also collected from the foam nest. Several other pairs were in amplexus in and around the wallow. In Vietnam, this species is known from the following provinces: Quang Binh (Phong Nha District), Ha Tinh (Chin Xai), Gia Lai

(An Khe District [= K Bang]), and Ba Ria-Vung Tau (as Cap St. Jacques) (Bourret 1942; Inger et al. 1999; Ziegler 2002; Ziegler et al. 2004). It has also been reported from Lang Son (Huu Lien), Phu Tho (Thanh Son, Ha Hoa), and Dong Nai (Cat Tien), but without reference to locality or voucher information (Ho 2002a; Nguyen and Ho 2002; Nguyen et al. 2000). This species is also known from India, Myanmar, Thailand, China (Xizang, Hainan, Guangxi, Fujian, and Yunnan Provinces), Laos (Vientiane Municipality, Champasak Province), and Cambodia (Cardamom Mountains) (Chanda 2002; Fei et al. 2005; Ohler et al. 2002; Stuart 2005b; Stuart et al. 2006; Teynie et al. 2004; Taylor 1962).

Philautus banaensis. THUA THIEN-HUE PROVINCE, Huong Thuy District, Binh Thanh Commune, IEBR 2307, 16°17'58"N, 107°33'18"E, elevation 109 m, 8 September 2005, R. H. Bain, T. Q. Nguyen, C. K. Dang, and T. D. Nguyen; collected calling from atop leaves, ~ 3 m high above a stream. This species is otherwise known from Quang Nam Province (Tra My District) and the type locality in Danang Province (Ba Na) in Vietnam (Bourret 1942; Stuart, *in press*). This species has previously been reported from Thua Thien-Hue and Thanh Hoa Provinces, but without reference to a distinct locality or voucher information (Ho 2002b; Nguyen, Ho, and Nguyen 2005; Nguyen and Hoang 2000; Orlov et al. 2002).

Rhacophorus annamensis. THUA THIEN-HUE PROVINCE, A Luoi District, Huong Nguyen Commune, Khe Coi Stream: AMNH A-169325, 16°15'32"N, 107°27'15"E, elevation ~ 101 m, 18 August 2005, R. H. Bain, T. Q. Nguyen, and M. V. Tran; from the side of a deep rocky pool. Other specimens were present on small branches overtop of the pool. Huong Thuy District, Binh Thanh Commune: AMNH A-169326, 16°17'49"N, 107°32'48"E, elevation 100–200 m, 9 September 2005, R. H. Bain, T. Q. Nguyen, C. K. Dang, and T. D. Nguyen; on a streamside rock. QUANG NAM PROVINCE, Tra My District, Tra Don Commune: AMNH A-163745, 15°11'41"N, 108°2'25"E, elevation 940 m, 19 March 1999, T. Q. Nguyen; AMNH A-163746, 15°11'41"N, 108°2'32"E, elevation 970 m, 22 March 1999 T. Q. Nguyen; AMNH A-163747, 15°11'30"N, 108°2'23"E, elevation 960–990 m, 13 March 1999, T. Q. Nguyen; AMNH A-163748, 15°11'41"N, 108°2'25"E, elevation 940 m, 26 March 1999, P. R. Sweet. Within Vietnam, this species has been reported from Quang Binh Province (Minh Hoa District, Phong Nha-Ke Bang), Gia Lai Province (An Khe District [= K Bang]), and Lam Dong Province (Daban) (Bourret 1942; Frost et al. 2006; Inger et al. 1999; Ziegler, Ohler et al. 2006). Nguyen, Ho, and Nguyen (2005) report this species from Tra My District and Thua Thien-Hue Province, and Orlov et al. (2002) report this species from Ninh Thuan, Lam Dong, Dak Lak, and Kon Tum Provinces, but neither refer to exact locality or voucher information. It is also known from Mondolkiri Province of Cambodia (Stuart et al. 2006).

Rhacophorus bipunctatus. THUA THIEN-HUE PROVINCE, A Luoi District, Huong Nguyen Commune: A169333, 16°14’32"N, 107°27’21"E, 17 August 2005, R. H. Bain, T. Q. Nguyen, and A. X. Tran; from foliage overhanging a large buffalo wallow. LAO CAI PROVINCE, Van Ban District, Liem Phu Commune, Cham Vai: IEBR 1197, 21°57.445'N, 104°20.963'E, elevation 1100 m, 28 June 2002, T.Q. Nguyen and H. V. Nguyen; collected from leaves ~ 1 m over a small, rocky stream in disturbed primary forest. In Vietnam, this species has also been reported from Quang Binh (Phong Nha Khe Bang N.P.), Ha Tinh (Huong Son District), and Gia Lai (Anh Khe), Provinces (Frost et al. 2006; Inger et al. 1999; Ziegler et al. 2004). Orlov et al. (2002) state that this species ranges from Gia Lai northwards to Ha Tinh Province, but without reference to any specific localities or voucher specimens. This species has been reported from Lao Cai (Van Ban), and Dong Nai (Cat Tien) Provinces, but without any reference to specific localities or voucher information (Nguyen and Ho 2002; Nguyen, Nguyen, and Ho 2005). This wide-ranging species is also known from India, Myanmar, Thailand, Xizang Province in China, Phongsalay and Sayaboury Provinces in Laos, and the Cardamom Mountains of Cambodia (Bourret 1942; Fei et al. 2005; Ohler et al. 2002; Stuart 2005b; Taylor 1962).

Rhacophorus calcaneus. HA TINH PROVINCE, Huong Son District, Huong Son Reserve, Rao An region: AMNH A-161404, 18°22'N, 105°13'E, elevation 200 m, 21 April 1998, D. A. Kizirian, and T. Q. Nguyen. THUA THIEN-HUE PROVINCE, A Luoi District, Huong Nguyen Commune, Da Stream: AMNH A-169328, 163929, 16°15'38"N, 107°26'38"E, 16 August 2005, R. H. Bain, T. Q. Nguyen, and A. X. Tran; calling from thin branches of streamside trees, ~ 2 m off the ground. Little A Ma Stream: AMNH A-169331,16°15'17"N, 107°26'59"E, elevation ~ 90 m, 21 August 2005, R. H. Bain, T. Q. Nguyen, and M. V. Tran. Nam Dong District, Thuong Lo Commune, tributary to the Cha May River: AMNH A-169332, 16°7'40"N, 107°44'44"E, elevation ~ 220 m, 1 September 2005, R. H. Bain, T. Q. Nguyen, V. P. Nguyen, V. T. Nguyen, and V. M. Ngo; from branch of a streamside tree, ~ 3 m high. In Vietnam, this species has been reported from Gia Lai (An Khe District [= K Bang]), and Quang Nam Provinces (Tra My District), as well as the Lam Vien Plateau (Bourret 1942; Frost 2006; Inger et al. 1999). It has been reported widely from the country (including Thua Thien-Hue and Quang Nam Provinces), but without specific localities or voucher information (Nguyen 2002; Nguyen, Ho, and Nguyen 2005). It is also known from Xe Kong Province, in Laos (Stuart 2005b).

Rhacophorus exechopygus. THUA THIEN-HUE PROVINCE, A Luoi District, A Roang Commune: IEBR 2011, nr. 16°04.636'N, 107°29.290'E, elevation ~ 680 m, 23 August 2005, R. H. Bain, T. Q. Nguyen, and V. S. Ho; atop a broadleaf on a shrub, ~ 3 m off the ground, ~ 3 m from the stream up a steep embankment. This species is known only from the Vietnamese provinces of Gia Lai (An Khe District [= K Bang]) and Quang Nam (Tra My District) (Bain and Nguyen 2002c; Inger et al. 1999). Orlov et al. (2002) report this species from Kon Tum Province, but without reference to specific locality or voucher information.

Rhacophorus kio. THUA THIEN-HUE PROVINCE, A Luoi District, Huong Nguyen Commune: AMNH A-169327, 16°14'32"N, 107°27'21"E, 17 August 2005, R. H. Bain, T. Q. Nguyen, and A. X. Tran; in amplexus on a branch overhanging a large buffalo wallow. This species has recently been shown to be separate from *Rhacophorus reinwardtii*, which is currently known from the Greater Sundas and the southern portion of the Malay peninsula. In Vietnam, this species has been reported from the following provinces (as *Rh. reinwardtii*): Lao Cai, Ha Tinh (Chin Xai, Khe Tho, Ke Do), and Gia Lai (An Khe District [= K Bang]) (Inger et al. 1999; Ohler and Delorme 2006; Orlov et al. 2001; Ziegler 2002; Ziegler et al. 2004). Several other accounts across Vietnam are

listed (Cao Bang [Nguyen Binh], Hai Duong [Chi Linh], Son La [Xuan Nha], Thanh Hoa [Thach Thanh, Ben En], Thua Thien-Hue [A Luoi], Da Nang [Ba Na], and Quang Nam [Nam Giang, Tay Giang] Provinces), but without specific locality or voucher information (Ho 2002b; Ho et al. 2001; Ho et al. 2005; Ho and Orlov 2000; Le 2000; Le and Nguyen 1999; Nguyen 2000; Nguyen 2005; Nguyen and Hoang 2000). This widespread species is also known from Thailand (although not on the Malay Peninsula), China (Guangdong, Yunnan Provinces), and Laos (Bokeo, Khammouan, Phongsaly, Huaphahn, Sayabourym Provinces) (Ohler and Delorme 2006; Stuart 2005b).

Rhacophorus orlovi. NGHE AN PROVINCE, Con Cuong District, Chau Khe Commune, Ngun Stream: AMNH A-161411, 19°2'17"N, 104°42'6"E, elevation 300 m, 27 April 1998, T. Q. Nguyen and D. A. Kizirian. LAO CAI PROVINCE, Van Ban District, Nam Tha Commune, tributary to Khe Pan River: AMNH A-168770, 21°56'24"N, 104°24'7"E, elevation 360–400 m, 15 September 2004, R. H. Bain, K. V. Doan, and V. T. Trieu; from the stem of a broadleaf plant, 1.5 m above the ground, ~ 4 m from the stream. THUA THIEN-HUE PROVINCE, A Luoi District, Huong Nguyen Commune, Little A Ma Stream: IEBR 2305, 16°15'17"N, 107°26'59"E, elevation ~ 90 m, 21 August 2005, R. H. Bain, T. Q. Nguyen, and M. V. Tran. Within Vietnam, this species is known from the following provinces: Ninh Binh (Cuc Phuong N.P.), Quang Binh (Phong Nha-Khe Bang N.P.), Ha Tinh (Ky Anh-Ke Go), Gia Lai (An Khe District [= K Bang]) (Stuart 2005a; Ziegler and Köhler 2001; Ziegler et al. 2002). It is also known from Thailand and Khammouan Province, Laos (Chan-ard 2003; Stuart 2005b).

Reptilia
Suborder Sauria
Family Agamidae

Calotes emma. BAC KAN PROVINCE, Ba Be Lake National Park, cave area, ca 1.5 km E of guest house: AMNH R-147066, 22°24'1"N, 105°37'54"E, 8 August 1997, D. R. Frost, and C. J. Raxworthy. THUA THIEN-HUE PROVINCE, Huong Thuy District, Binh Thanh Commune: AMNH R-154613, stream nr. 16°17'49"N, 107°32'48"E, elevation 100–200 m, 9 September, R. H. Bain, T. Q. Nguyen, C. K. Dang, and T. D. Nguyen. This widespread species has been reported from across continental southeast Asia (e.g., Boulenger 1885; Smith 1935; Stuart et al. 2006; Taylor 1963; Ziegler 2002; Ziegler et al. 2004), however these are new provincial records within Vietnam. Nguyen, Ho, and Nguyen (2005) report this species from Bac Kan, but without reference to specific locality or voucher information.

Pseudocalotes floweri. VIETNAM, KON TUM PROVINCE, Kon Plong District, Mang Canh Commune, forest nr. Nuoc Ka Stream: IEBR 330, 14°41.950'N, 108°12.095'E, elevation 1200 m, 10 January 2001, T. Q. Nguyen; in secondary forest. The specimen is female, snout-vent length 68.2 mm; head length nearly twice its breadth; upper labials 8 left side, 10 right side; lower labials 9 left side, 8 right side; eye diameter 4.8 mm (more than twice the tympanum of 2.1 mm); snout length 9.2 mm (nearly twice the obit diameter); six scales between nasal and supraorbital; nuchal crest with 8 erect spines; length of finger III = IV; 52–56 scales round the middle of the body; tail length 151.2 mm. Body compressed; upper head scales keeled; series of enlarged scales forming a λ-shaped figure on forehead; dorsal scales feebly keeled, all pointing backwards and downwards; median ventrals small and strongly keeled; 19 scales under finger IV; blade-like outer keels under toe III, not bicarinate; tail compressed, covered with keeled scales. In life, this specimen is brown, enlarged dorsal scales bluish, spines are light brown; radiate dark brown lines around eye to supraorbital ridge; limbs yellow with dark brown irregular bands; dark brown gular spot, and 10 dark brown spots on the tail (which fade in preservative). This species is otherwise known from Chanthaburi, Thailand and the Elephant Mountains (Bockor [= Bokor]), Cambodia (Smith 1935; Taylor 1963; Hallerman and Böhme 2000). This is the first country record for Vietnam. Our specimen is shorter than those previously described (snout–vent length for type specimen 98 mm; 95 mm for referred specimen) (Boulenger 1912; Smith 1935; Taylor 1963 described specimens from Thailand without reporting their snout–vent lengths).

Pseudocalotes microlepis. BAC KAN PROVINCE, Ba Be District, Ba Be National Park, cave area, ca 1.5 km E of guest house: AMNH R-147071, 22°24'1"N, 105°37'54"E, 8 August 1997, D. R. Frost, and C. J. Raxworthy. In Vietnam this species is also known from Quang Ninh, Danang (Ba Na), and Lam Dong (Lang Bian, Camley [= Cam Ly]) Provinces (Ziegler, Thanh et al. 2006). Otherwise, it is known from Myanmar, Thailand, China (Hainan Island, Guizhou Province), and Laos (Phong Saly [= Phong Sali Province]) (Bourret 1939b; Smith 1935; Hallerman and Böhme 2000; Zhao and Adler 1993).

Family Dibamidae

Dibamus greeri. THUA THIEN-HUE PROVINCE, A Luoi District, A Roang Commune: AMNH R-154630/IEBR 2311, nr. 16°04.636'N, 107°29.290'E, elevation ~ 650 m, 26 August, 2005, R. H. Bain, T. Q. Nguyen, and V. S. Ho; under a streamside rotting log. This specimen conforms precisely with the description of the holotype, including the diagnositic characters: incomplete medial-rostral nasal suture; one postocular; two supra labials; very large frontal; posteromedial edge of infralabials bordered by one long, narrow scale; 20 mid-body scale rows (the tail is partially regenerated). In life the body is purplish-brown with a blue-grey mid body transverse band. A second blue-grey transverse band just posterior to the head is evident in preservative. This species is otherwise only known from its type locality in An Khe District [= K Bang], Gia Lai Province (Darevsky 1992).

Family Scincidae

Plestiodon quadrilineatus. HA TINH PROVINCE, Huong Son District, Huong Son Reserve, Rao An Region, nr. top of Po-mu Mountain: AMNH R-147116, elevation 900–1200 m, 22 April 1998, T. Q. Nguyen. AMNH R-147117, nr. 18°22'N, 105°13'E, April 1998, Diana Silva. In Vietnam, this species is known from Lang Son Province (Man Son Mountains [= Mau Son Mountains]) and Quang Binh Province (Phong Nha), (Bourret 1939a; Darevsky and Orlov 2005; Taylor 1935; Ziegler et al. 2004). This species has been reported from Cao Bang (Nguyen Binh), Quang Ninh (Ba Mun), Son La (Moc Chau, Cao Pha), Thanh Hoa (Ben En), Ha Tinh, Nghe An (Pu Mat, Pu Huong), and Da Nang (Ba Na) Provinces, but without reference to a precise locality or voucher information (Ho et al. 2005; Hoang et al. 2005; Le 2000; Le and

Hoang 2001; Le and Nguyen 1999; Nguyen 2000; Nguyen 2005; Nguyen, Ho, and Nguyen 2005; Nguyen and Hoang 2000). In addition, this species is known from Thailand, China (Guangdong, Hong Kong, Guangxi, Sichuan, Hainan Provinces), and Cambodia (Smith 1935; Taylor 1935; Zhao and Adler 1993).

Sphenomorphus cryptotis. LAO CAI PROVINCE, Van Ban District, Nam Tha Commune, tributary to Khe Pan River: AMNH R-153698, 153699, 153700, 21°56'24"N, 104°24'7"E, elevation 360–400 m, 15 September 2004, R. H. Bain, K. V. Doan, and V. T. Trieu. AMNH R-153701, 21°56'39"N, 104°24'12"E, elevation 331 m, 17 September 2004, R. H. Bain, K. V. Doan, and T. V. Trieu. All specimens were collected sleeping on leaves or small branches overhanging a stream. This species is only known from Quang Ninh (Uong Bi Town, Yen Tu Mountain), and Nghe An (Quy Chau District) provinces in northern Vietnam (Darevsky et al. 2004).

Sphenomorphus tridigitus. QUANG NAM PROVINCE, Tra My District, Tra Don Commune, Mt. Ngoc Linh: IEBR 73, 15°11.688'N, 108°02.413'E, elevation 940 m, 21 March 1999, C.A. Johnson; IEBR 74. 15°10.762'N, 108°02.731'E, elevation 1470 m, P. R. Sweet. Both specimens were collected in pit fall traps, which were set near the ridges of the mountainous primary forest. Our specimen agrees with a recent redescription (Greer et al. 2006), including discrepancies with the type. As with the specimen of Greer et al. (2006), our specimens include a frontonasal with two widely separated prefrontals, and fusion of nasal and first infralabial scales. The loreal scale is not fused with the preocular, as Greer et al. (2006) believe it may be in the poorly preserved holotype. In Vietnam, this species is only known from Thua Thien-Hue Province (Bach Ma) from the original description (Bourret 1939c). It otherwise only known from Champasak Province, Laos (Teynie et al. 2004).

Tropidophorus cocincinus. THUA THIEN-HUE PROVINCE, Huong Thuy District: Binh Thanh Commune, tributary to Dau River: AMNH R-154623, nr. 16°17.995'N, 107°33.307'E, elevation 109 m, 8 September 2005, R. H. Bain, T. Q. Nguyen, C. K. Dang, and T. D. Nguyen; from a rocky shore of the stream. A Luoi District, Huong Nguyen Commune, A Lieng Stream: AMNH R-154624, 16°14'10"N 107°27'26"E, elevation ~ 160 m, 17 August 2005, R. H. Bain, T. Q. Nguyen, A. X. Tran; from a rocky portion of the stream edge in the water. A Luoi District, Huong Nguyen Commune: AMNH R-154625, 154626, nr. 16°14'26"N 107°27'11"E, elevation ~ 152 m, 19 August 2005, R. H. Bain, T. Q. Nguyen, and M. V, Tran; collected from a rocky portion of the stream edge in the water. In Vietnam this species is known from Kon Tum (Kon Tum) and Quang Binh (Phong Nha-Khe Bang) Provinces (Bourret 1939c; Darevsky and Orlov 2005; Smith 1935; Ziegler et al. 2004). This species has been reported from Thua-Thien-Hue (A Luoi) and Da Nang (Son Tra) Provinces, but without specific locality or voucher information (Dinh and Nguyen 2000; Ho 2002b; Nguyen, Ho, and Nguyen 2005). It is otherwise known from Laos (Xe Kong Province) and Thailand (Greer and Biswas 2004; Taylor 1963).

Tropidophorus hainanus. HA TINH PROVINCE, Huong Son District, Huong Son Reserve, Rao An region: AMNH R-147123, 18°20'47"N, 105°14'10"E, elevation 870 m, 9 May 1998, D.T. Pham. LAO CAI PROVINCE, Van Ban District, Nam Xay Commune: IEBR 1219, 21°58.731'N, 104°01.403'E), elevation 1550 m, 6 July 2002, Nguyen Quang Truong and Nguyen Van Hung; disturbed primary forest. This latter specimen was found on the ground near the steep bank of a small rocky stream within a hardwood forest. In Vietnam, this species has been reported from Tonkin (Tam Dao, Ngan Son) [= Tam Dao Mt., Vinh Phuc Province and Ngan Son District, Bac Kan Province], Nam Dinh (Giao Thuy District), and Cuc Phuong N.P. (Cuc Phuong borders Hoa Binh, Thanh Hoa, and Ninh Binh provinces, but the record from Bobrov [1993] does not stipulate from which part of the park the species was found) (Bourret, unpubl. 1937a, 1939b, 1939c; Bobrov 1993). Ziegler, Thanh et al. (2006) also list Bac Kan, Cao Bang, Dak Lak, Ha Tay, Hai Duong, Kon Tum, Lai Chau, Phu Tho, and Quang Ninh provinces of Vietnam as having records of this species, but they cite Nguyen (2005) and Orlov (2005), neither of which give precise locality or voucher information. Outside of Vietnam, this species is known from China (Hainan, Jiangxi, Guangxi provinces) (Smith 1935; Zhao and Adler 1993).

SUBORDER SERPENTES
FAMILY COLUBRIDAE

Dendrelaphis ngansonensis. QUANG NAM PROVINCE, Tra My District, Tra Don Commune, AMNH R-148550, nr. 15°11.459'N, 108°2.523'E, elevation 1100 m, 1 April 1999, P. R. Sweet. In Vietnam this species is known from the following provinces Cao Bang (Ngan Son), Vinh Phuc (Tam Dao), Quang Binh (Phong Nha Khe-Bang), Ha Tinh ("Chuc A", Ke Anh-Ke Go, Chin Xai), Thua Thien-Hue (Bach Ma), Col des Nuages nr. Tourane = (Quang Nam Danang Province nr. Danang City), and in Cuc Phuong N.P. (this park borders Hoa Binh, Thanh Hoa, and Ninh Binh provinces, but the record from Ziegler and Vogel [1999] does not stipulate from which part of the park the species was found) (Bourret 1936; Orlov et al. 2000; Ziegler 2002; Ziegler et al. 2004). Nguyen, Ho, and Nguyen 2005 state that it is found in Quang Nam Province (Chu Lai), but without specific locality or voucher information. This species is also known from Xieng-Khouang (= Xieng Khoang) Province, Laos (Deuve 1970).

Dinodon septentrionalis. THUA THIEN-HUE PROVINCE, Nam Dong District, Thuong Lo Commune, Cha May River: AMNH R-154176, 16°7'40"N, 107°44'44"E, elevation ~ 220 m, 1 September 2005, R. H. Bain, T. Q. Nguyen, V. P. Nguyen, V. T. Nguyen, and V. M. Ngo; collected from among tree roots next to a cascade. In Vietnam, this species has been reported from the following provinces: Lai Chau, Lao Cai, Bac Kan, Cao Bang, Vinh Phuc, Nghe An, Quang Binh, Ha Tinh (Orlov et al. 2003). This wide-ranging species is also known from India, Myanmar, Thailand, China (Yunnan Province), Laos (Kiang Kuoang [= Xieng Khoang] Province), and Cambodia (Mondolkiri Province) (Bourret 1936; Orlov and Ryabov 2004; Smith 1943; Stuart et al. 2006).

Euprepiophis mandarinus. HA TINH PROVINCE, Huong Son District, Huong Son Reserve, Rao An region, top of Po-mu Mountain: IEBR 2302, 18°20'53"N, 105°14'38"E, elevation 1010–1080 m, 8 May 1998, T.X. Le. In Vietnam this species is known from Lao Cai (Mt. Fan Si Pan, Chapa [= Sa Pa], Ngo Toi), Lang Son (Mau Son), Vinh Phuc (Tam Dao), and Tuyen Quang (Na Hang District) Provinces (Angel and Bourret 1933; Bourret 1936; Le and Ziegler 2004; Orlov et al. 2000; Parker 1925). This species has been reported from Son La (Ta Sua, Xuan Nha), as well as Ha Tinh (Huong Son), but without a specific locality or voucher in-

formation (Nguyen 2000; Nguyen 2005; Nguyen, Ho, and Nguyen 2005). Elsewhere it is known from India, Myanmar, and several provinces across China (Smith 1943; Zhao and Adler 1993).

Pareas carinatus. QUANG NAM PROVINCE, Quang Nam, Tra My District, Tra Don Commune, Ngoc Linh Mountain: AMNH R-148551, elevation 980 m, 17 March 1999, T. Q. Nguyen. Smith (1943) stated that in Vietnam, this species was found "below 19°", otherwise it has only been specifically reported from Vinh Phuc (Tam Dao), Gia Lai (Son Lang), Quang Tri (Quang Tri), Quang Bonh (Phong Nha), Tay Ninh (Tay Ninh), and Dong Nai (Trang Bom) Provinces (Campden-Main 1969; Orlov et al. 2000; Szyndlar and Nguyen 1996; Ziegler, Ohler et al. 2006). This species has also been reported from Lam Dong (Lac Duong), Dong Nai (Cat Tien), and Tay Ninh (Ba Den Mt.), but without reference to specific voucher or locality information (Ho and Nguyen 1982; Nguyen and Ho 2002; Pham et al. 2000). It is otherwise known from Myanmar, the Greater Sundas, Thailand, China, Laos, and Cambodia, (Manthey and Grossmann 1997; Pauwels et al. 2003; Saint Girons 1972; Smith 1943; Stuart and Emmett 2006; Zhao and Adler 1993).

Pseudoxenodon macrops. LAI CHAU PROVINCE, Mount Fan Si Pan: AMNH R-147147, elevation 2,020 m 19 August 1997, D. R. Frost and C. J. Raxworthy. HA TINH PROVINCE, Huong Son District, Huong Son Reserve, Rao An Region: AMNH R-147148, nr. 18°22'N, 105°13'E, 9 May 1998, via D. A. Kizirian. This species has previously been reported from Lao Cai (Ngoi Tio, Sa Pa), Vinh Phuc (Tam Dao), Da Nang (Ba Na), and Lam Dong (Fyan, Da Lat, Lang Bian) provinces (Campden-Main 1969; Orlov et al. 2000; Parker 1925). It is otherwise a widespread species throughout southeast Asia, from the eastern Himalayas to the Malay peninsula and east through Myanmar, Thailand, China and the Indochinese peninsula (Farkas and Fritz 1999; Smith 1943; Taylor 1965; Zhao and Adler 1993).

Sibynophis collaris. BAC KAN PROVINCE, Ba Be District, Ba Be National Park: AMNH R-147156, 7 August 1997, D. R. Frost and C. J. Raxworthy; beside a cascade. HA TINH PROVINCE, Ke Go Nature Reserve, Mon Stream: AMNH R-147157, 11 April 1998, T.Q. Nguyen and D. A. Kizirian. In Vietnam, this species is known from Lai Chau (Muong Nha), Nonh Bonh (Xom Bong [= Cuc Phuong]), Quang Binh (Phong Nha), Quang Tri (Xa Huc), Thua Thien-Hue (Hue), Gia Lai (Son Lang), Lam Dong (Bao Loc, Da Lat, Lang Bian), and Dong Nai (Bien Hoa) Provinces. (Campden-Main 1969; Szyndlar and Nguyen 1996; Ziegler et al. 2004). In Vietnam it has also been reported from Nghe An (Pu Mat, Pu Huong, Ky Son), Ha Tinh (Huong Son), Thua Thien-Hue (A Luoi), and Dong Nai (Cat Tien) Provinces, but without any voucher information (Ho 2002b; Le and Hoang 2001; Nguyen 2000; Nguyen and Ho 2002; Nguyen, Ho, and Nguyen 2005). This species is widespread across India, Nepal, Myanmar, Thailand, China, Laos, and Cambodia (Smith 1943).

Sinonatrix aequifasciata. LAO CAI PROVINCE, Van Ban District, Nam Tha Commune, tributary to Nam Tha River: AMNH R-153712, 153713, 21°55'23"N, 104°22'43"E, elevation ~ 640 m, 3 September 2004, R. H. Bain, T. Q. Nguyen, K. V. Doan, and A. C. Lu; from tree branches overhanging fast flowing water. Tributary to Khe Pan River: AMNH R-153714, 21°56'24"N, 104°24'7"E, elevation 360–400 m, 16 September 2004, R. H. Bain and K. V. Doan. In Vietnam, this species has been reported from Ha Giang (Vi Xuyen District), Vinh Phuc (Tam Dao) and Nghe An (Ky Son) Provinces (Bain and Nguyen 2004b; Orlov et al. 2000; Vogel et al. 2004; Ziegler and Hoang 2005). This species has also been reported from Lao Cai (Van Ban), Cao Bang (Nguyen Binh), and Bac Giang (Luc Nam) provinces, Vietnam, but without reference to specific locality or voucher information (Ho et al. 2005; Nguyen et al. 2002; Nguyen, Nguyen, and Ho 2005). This species is otherwise known from China (Guangxi, Guangdong, Hong Kong, Hainan, Fujian, Guizhou, Hunan, Jiangxi, Sichuan, Zhejiang) (Zhao and Adler 1993; Zhou and Yu 2002).

Sinonatrix percarinata. THUA THIEN-HUE PROVINCE, A Luoi District, A Roang Commune: IEBR 2312, nr. 16°04.636'N, 107°29.290'E, elevation ~ 680 m, 23 August 2005, R. H. Bain, T. Q. Nguyen, and V. S. Ho; on vegetation overhanging a stream, ~ 2 m above the surface. In Vietnam, this species is otherwise known from Lao Cai (Chapa [= Sa Pa], Thai Nien, Ngoi Toi), Ha Giang (Yen Minh District), Bac Kan (Ngan Son), Vinh Phuc (Tam Dao), Bac Giang (An Lac, Thanh Son), Quang Binh (Phong Nha Khe Bang N.P.), Ha Tinh (Chin Xia, Ke Go-See), and Kon Tum (Kon Tum, Kon Plong) provinces (Bain and Nguyen 2004b; Bourret 1937b, 1939; Campden-Main 1969; Orlov et al. 2000; Parker 1925; Szyndlar and Nguyen 1996; Ziegler 2002; Ziegler et al. 2004). This species has also been reported from Cao Bang (Nguyen Binh), Lang Son (Huu Lung), Son La (Muong Do, Xuan Nha), Hoa Binh (Da Bac), Bac Giang (Luc Nam), Thua Thien-Hue (A Luoi, Hung Thuy), and Dong Nai (Cat Tien) Provinces, but without reference to specific locality or voucher information (Dang et al. 1975; Ho 2002b; Ho et al. 2005; Nguyen 2005; Nguyen and Ho 2002; Nguyen et al. 2000; Nguyen et al. 2002; Nguyen, Ho, and Nguyen 2005). This species is otherwise known from India, Myanmar, Thailand, China (Hainan, Chekiang, Jiangxi, Fujian, Guangdong, Guangxi, Kweichow, Sichuan, and Hupeh Provinces), and Taiwan (Captain et al. 1998; Smith 1943; Zhao and Adler 1993; Zhou and Yu 2002).

Family Viperidae

Protobothrops mucrosquamata. LAO CAI PROVINCE, Van Ban District, Nam Tha Commune, forested stream above Nam Tha River: AMNH R-153720, 21°55'13"N, 104°22'15"E, elevation ~ 950 m, 5 September 2004, R. H. Bain, T. Q. Nguyen, K. V. Doan, V. T. Trieu, and A. L. Chu. In Vietnam, this species has been reported from Ha Giang (Du Gia Commune), Cao Bang, Bac Kan (Ngan Son), Thai Nguyen, Vinh Phuc (Tam Dao), Quang Ninh (Nam Son, Quan Lan), Ha Tay, Hai Duong, Ninh Binh, Nghe An, Ha Tinh (Ky Anh-Ke Go), Thua Thien-Hue (A Luoi), Gia Lai, and Kon Tum Provinces (Bourret 1936; Orlov et al. 2000; Szyndlar and Nguyen 1996; Ziegler 2002; Ziegler, Thanh et al. 2006). This widespread species is otherwise known from Bangladesh, India, Myanmar, and China (Leviton et al. 2003; Smith 1943; Zhao and Adler 1993).

Viridovipera vogeli. THUA THIEN-HUE PROVINCE, A Luoi District, A Roang Commune, stream at Ho Chi Minh Highway marker kilometer 398+700: AMNH R-154632, 16°4'28"N, 107°29'14"E, elevation ~ 653 m, 23 August 2005, R. H. Bain, T. Q. Nguyen, V. S. Ho, and V.T. Le; from flat rocky stream bank. HA TINH PROVINCE, Huong Son District, Rao An Region, nr. top of Po-mu Mountain: AMNH R-147162, elevation 900–1200

m, 22 April 1998, T. Q. Nguyen. In Vietnam, this species is known from Quang Binh, Gia Lai (An Khe =[K Bang], Krong Pa), Quang Nam, and Danang (Ba Na) Provinces (Malhotra and Thorpe 2004; Malhotra et al. 2004; Orlov et al. 2003). Nguyen, Ho, and Nguyen (2005) report this species from A Luoi, but without any specific locality or voucher specimen information. This species is otherwise known from Thailand, Laos (Champasak), and Cambodia (Mondolkiri Province, Cardamom Mountains) (David et al. 2001; Malhotra et al. 2004; Stuart et al. 2005).

Acknowledgments.—This work was supported by funding from the National Science Foundation (grant no. 98–70232 to the Center for Biodiversity and Conservation, AMNH), The John D. and Catherine T. MacArthur Foundation, NASA grant no. NAG5-12333, 2002–2005 (to D. Frost), the Green Corridor Project of WWF's Greater Mekong Programme, and the Hoang Lien Project of FFI Indochina – Vietnam Programme. We gratefully acknowledge Eleanor J. Sterling, Le Xuan Canh, and Nguyen Xuan Dang for program support. Further, we acknowledge the assistance and support of Khuat Dang Long, Nguyen Tien Hiep, Ho Thu Cuc, and Nguyen Truong Son (IEBR); Melina Laverty, Paul Sweet, and Mary De Jong (AMNH); Steven Swan and Nguyen Bich Ha (FFI); Jonathan Eames, and A.W. (Jack) Tordoff (Birdlife International – Vietnam Programme); and Hoang Ngoc Khanh, Chris Dickinson, and Van Ngoc Thinh (Green Corridor Project, WWF). We thank Bryan Stuart for helpful comments on the manuscript. We also thank Darrel Frost for valuable discussions.

All collecting and euthanasia methods were performed in accordance with the AMNH Institutional Animal Care Needs Committee (protocol no. 1998–12). Collecting and export permits were granted by the Forestry Protection Department (FPD), Ministry of Agriculture and Rural Development, Vietnam. We acknowledge the offices of FPD for assistance: Central FPD, Hanoi; and the regional FPD offices of Lao Cai, Ha Giang, Nghe An, Ha Tinh, Thua Thien-Hue and Quang Nam Provinces. We are grateful to the regional People's Committees for allowing access and to local guides and assistants, too numerous to list, who make this work possible.

e-mail: mvburger@dctexas.net

Like a locomotive slowly building up steam, the herpetoculture juggernaut commercially came of age sometime in the late 1980s to early 1990s. After years of simply just trying to keep amphibians and reptiles alive in captivity, this plateau marked the beginning of an era of not only successful maintenance of these fascinating animals, but also standardized propagation that could, at least in some cases, be called "cookbook." Since the early 1990s amphibian and reptile books and magazines have proliferated, products specifically targeting these animals have appeared on the store shelves, expos have become a weekly event, and through the use of a little thing known as the internet, the global community is suddenly within reach and ideas are quickly disseminated.

Several species come to mind as being the most successful in herpetoculture, these being leopard geckos (*Eublepharis macularius*), corn snakes (*Pantherophis guttata*), and ball pythons (*Python regius*). The reasons for the success of these three species are probably many, including among others, their relatively small size, easy adaptability to captivity, and attractiveness. A further common feature is the incredible variety of selectively bred color and pattern phenotypes available and, at least in the case of ball python designer morphs, the tremendous prices they command.

Who else would be better suited or more qualified to write about or simply more in love with the subject of this new book than Dave and Tracy Barker? *Pythons of the World, Volume II. Ball Pythons: The History, Natural History, Care, and Breeding* is a colossal effort from two skilled biologists/herpetoculturists who have spent practically their entire lives working with pythons. As is the case with the first volume in the series, *Pythons of the World, Volume I. Australia*, the current book is an incredible photographic and literary feast.

As a prelude, the book begins with Contents, Acknowledgments, Introduction, About This Book, About the Pictures, and The Golden Age of Herpetoculture. The Barkers describe how their obsession with ball pythons started—getting one, then another, then another, and how things "began to spiral out of control." This indeed is something many reptile enthusiasts (including some professional herpetologists) can identify with.

The first chapter, "Introducing the Ball Python," sets the groundwork for the reader and covers the early history of pythons in Europe, classification, habitat and distribution, life span, natural history, abundance, defensive behavior, and the reasons why they are so popular. Chapter Two, "The Relationships of Humans and Ball Pythons in Africa" includes both python worship and modern day human interaction with the ball python. Beginning with the humorous opening statement "We are not the first people to revere and even worship ball pythons," the authors describe how ophiolatry, or the worship of snakes, affected the lives of the Whydah,an African culture inhabiting the border region between present day Benin and Nigeria. Pythons were regarded as gods incarnate and the penalty for killing one was severe.

Chapter Three, "The Physical Ball Python," describes the ball python, with information on physical characteristics, size, intelligence, sensory abilities, the reproductive system, and determination of sex. This chapter is particularly useful to keepers in that it describes as well as illustrates sex determination techniques such as probing and manually everting the hemipenes of a male (also known as popping). The following chapter, "Skin and Shedding," covers the outer surface of the ball python and ends with practical information on shedding problems.

Chapter Five, "The Basis of Color and Pattern," is devoted to the mechanics of the various chromatophores and how they relate to color and pattern. The chapter includes "A Glossary of Color Terms" with definitions of the terminology used in the discussion. Chapter Six, "The Morphs," takes one to the very core of the success of ball pythons in herpetoculture. Eighteen pages cover everything from why morphs have become popular, naming a morph, to wild morphs (those found in nature), and designer morphs (those produced in captivity from crossing wild morphs). Fifty-three pages of color photographs featuring over 240 individual ball python morphs follow.

The next fourteen chapters focus on husbandry related issues and begin with what to look for when acquiring a ball python (Chapter 7, "Choosing a Ball Python"). The next chapter, "Transporting Ball Pythons," covers everything one should know about packing and shipping — including importing and exporting CITES regulated species such as ball pythons. "The Ultimate Snake Room," "Snake Room Equipment and Supplies," and "Snake Cages" (Chapters 9–11) together constitute a thorough checklist (with explanations) of everything that should be considered when housing these snakes.

The Barkers begin Chapter 12, "Temperatures," with a nice discussion on what exactly is an optimal temperature for a snake. Too often captive snakes are maintained at subpar temperatures

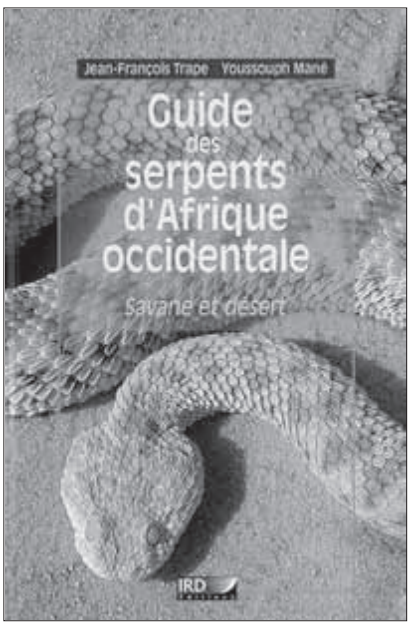
with complete disregard for the fact that they behaviorally thermoregulate to control their temperatures. Working at a zoo, I found the next chapter, "Maintenance," particularly poignant in that it discusses my regular working routine: cleaning, disinfecting, and quarantining. However, regular maintenance is an essential area that is neglected by many who maintain snakes. Chapter 14, "Feeding," explains why ball pythons acquired the reputation of being recalcitrant feeders in captivity. Sound, practical information follows, touching all the bases from when, what, and how much to feed, to the presentation of food, to the last ditch efforts of force feeding a reluctant snake. Accidents occasionally happen during feeding and the snake may mistake your hand for the food being presented which opens the door, hence Chapter 15, "Snake Bites."

The word "herpetoculture," defined as maintaining and propagating reptiles, strikes to the heart of Chapter 16, "Breeding Ball Pythons." One of the very reasons why reptiles have gained popularity in recent years is not only because of their innate physical and behavioral features, but also because they can and do reproduce in captivity. Having bred literally thousands of ball pythons (as well as other reptiles), the authors are more than capable of delivering the message behind the mechanics of reproducing this species. Chapter 17, "Eggs, Incubation, and Hatching," flows naturally from the previous chapter and thoroughly covers eggs and their management.

"Medical Matters" (Chapter 18) focuses on health issues including how to find a local veterinarian who specializes in reptiles. One may question why the subject of the next chapter, "Eradicating Snake Mites" was not included in the previous chapter. For those of us who have had to deal with large infestations of snake mites, the answer is very understandable: there are very few circumstances that are as life altering as having a collection affected by mites. Not only do they feed upon blood, but mites have also been implicated as possible vectors for diseases that may debilitate an entire collection. Practical information about recognizing and eliminating mites is treated by the authors as a military-style battle plan.

The closing sections of this book include the chapter "Basic Genetics for Python Breeders" — an introduction into the basic principles of genetics and inheritance. A glossary of anatomical terms (Appendix I) and a quick reference to many (233) of the ball python morphs (Appendix II) follows, with the book finishing off nicely with an extensive bibliography of all published references concerning ball pythons (including images), Literature Cited, and Index.

Very few errors or problems could be found in this book. The most noticeable, however, were the faint captions accompanying the photographs and figures which made reading the smaller captions difficult at best. According to one of the authors, this unfortunate mistake resulted from a misunderstanding between the layout studio and the printer (D. Barker, pers. comm.). A short perusal into the sensory abilities of ball pythons in Chapter Three "The Physical Ball Python," brought my attention to a citation for Young (2003) on page 25. Interested in locating the particular reference, I skipped back to the Literature Cited section on page 314 and found the author's name and the paper's title, yet a publication reference wasn't given. Another problem I found was a lack of Latin nomenclature accompanying the popular names of some of the pythons mentioned in the text. I had the feeling that I knew what a Lesser Sundas Python and a Halmahera Python were (page 44), but common names are not necessarily common to all readers.



Written primarily for the Ball Python enthusiast, but highly useable by all snake keepers, *Pythons of the World, Volume II* is a comprehensive effort that easily distances itself from any other husbandry book on this or any other snake species. It is very easy to read and the depth of coverage in the husbandry chapters alone is simply astounding, leaving few stones unturned. Coupled with superb photography and excellent line drawings, the authors have produced a solid effort that should become a classic for years to come.

I had been patiently awaiting the arrival of this second volume in the *Pythons of the World* series for the last ten years. In that time, my eyesight and lower back have slowly deteriorated to the point of requiring attention. Was it worth the wait? You bet.

The herpetological literature of West Africa has been of little use to the naturalist, particularly where snakes are concerned. Some good papers have been published, for example Dunger's series of papers in the *Nigerian Field* (1971a, 1971b, 1972, 1974) and Doucet's papers on the Ivory Coast snakes (1963), but these are hard to find. However, the books—for example Leeson (1950), Villiers (1950, with several new editions since, but little improved) and Roman (1980)—have been mostly characterized by a lack of maps, a poor selection of black and white photographs, often of specimens that are long-dead, mutilated or distant from the camera, fairly useless line drawings, no common names, and no attempt to make the data accessible to non-specialists. George Cansdale's handy little book (1961, reprinted in 1973) is a notable exception, with its reasonably accurate color paintings and sensible selection of species, although it is somewhat biased towards snakes known from Ghana. A decent attempt to improve the situation was made by

Chippaux (1999), although his book is marred by lack of common names and an arcane selection of color pictures, some of which are misidentified (see the review by Hughes 2000). So it is a pleasure to come across a book on West African snakes that is thorough, sound, illustrates all its subjects in color photographs and is accessible to the interested naturalist.

Trape and Mane's book covers the 81 species of snake that are deemed by the authors to inhabit the savanna, semi-desert, and desert of western Africa, north of latitude 9°N. Species solely inhabiting forest and woodland are excluded, although some genuine rainforest areas lie within the map boundaries. The baseline data for this book are derived from two large collections. One comprises 13,000 snakes, mostly from Senegal and Mali, but with some from Mauritania, Niger, and Guinea. These are preserved in the IRD research center in Dakar, Senegal, where Mane is the curator. The other is a collection of 4000+ preserved snakes from Burkina Faso, deposited in the National Scientific and Research Centre in Ouagadougou by the late eccentric Spanish priest Pere Benigno Roman.

The aim of this book, stated in the introduction, is to assist with the rapid identification of the snakes of six main countries of western Africa (Senegal, the Gambia, Mauritania, Mali, Niger, and Burkina Faso). The authors emphasize the significance of snakebite in western Africa, which at 10 cases per 100,000 inhabitants per year is, according to the authors, higher than the road accident deaths in Africa and Europe. Next, there are sections on snakebite (including details on treatment), the climate and vegetation of the region, identification, capture and preservation of snakes, and familiar and specific keys to all species, plus some useful tables comparing scale counts, sizes, etc. The environmental section includes 16 color photographs of habitats, ranging from the desert and oases to the well-wooded Guinea Savanna, and a rainfall map. The descriptions of the 81 species are in classic user-friendly, field guide style, with all the information in one place. Each species gets a double-page spread, with two photographs occupying an entire page; the map, description, and drawings of head scales (in plan and profile) are on the facing page. The book concludes with an eight-page bibliography and an index of scientific names. It is very nicely produced, slightly larger than octavo, tough and well bound, on glossy paper. There are some fascinating pictures in addition to the species illustrations, for example, the lady receiving local treatment for an *Echis* bite in the form of a cow dung poultice.

As anyone who has been involved in assisting the public to identify snakes will tell you, what they want are decent, large color illustrations. The big, mostly half-page pictures, nearly all taken by Trape, fit that bill exactly. Most show a whole animal and a close-up, but some show two color forms. There are species here that I don't think have ever been illustrated in color before, for example *Haemorrhois dorri* and the red-banded form of *Lycophidion albomaculatum*. The relatively large maps, showing western Africa from 18°W to 16°E, and 9° to 27°N, are divided into degree squares and national borders are shown. A locality is marked by red shading of the relevant square. In addition to the six countries mentioned above, the map also shows parts of Western Sahara, Algeria, Libya, Chad, western Cameroon, and the northern sectors of the countries of the West African seaboard, from Nigeria west to Guinea, and relevant records for the featured species within those countries are given. The description includes names (French, scientific, English) and a few lines on rapid identification plus notes under the headings Size, Distribution and Habitat, Description (scale data and color/pattern), and Natural History.

The distribution maps give nice insight into West African zoogeography. The high country of East and Southern Africa is full of fragmented habitats, each with their quota of endemic species, often confined to a single mountain range or high forest ("and all waiting to become extinct," as a colleague once cynically remarked to me). Western Africa is very different. With the exception of a few isolated massifs, most of the region is flat country, largely below 500 m altitude. The differing vegetation and climatic zones occupy huge east-west swaths, changing only as one travels north into increasing aridity. In West Africa one can drive hundreds of kilometers in an east-west direction and see very little variation in either altitude or habitat. This lack of habitat diversity is reflected in the distributions shown here; no fewer than 58 of the 81 species extend over 30 degrees of longitude. Consequently only one "single-country" endemic species is featured, *Mehelya gabouensis*, although there are a few snakes that are endemic to the southwestern corner of West Africa (e.g., *Rhinoleptus koniaguiu*, *Lycophidion albomaculatum*, *Elapsoidea trapei*). The featured snakes fit into clear faunal groups: Pan-African savanna species (*Bitis arietans*, *Naja nigricollis*), West African savanna forms (*Psammophis elegans*, *Dromophis praeornatus*), desert species (both species of *Cerastes*, *Malpolon moilensis*). There are also a few examples of what Hughes (1983) calls "East African invaders" (*Hemirhagerrhis nototaenia*, *Eryx colubrinus*) and a couple of large, genuine forest snakes (*Toxicodryas blandingi* and *Dendroaspis viridis*) whose size and consequent mobility have enabled them to colonize the woodland of the Casamance and River Gambia.

Their large collections and familiarity with the snakes of the area have enabled Trape and Mane to have a confident shot at getting rid of what is the curse of African herpetology, dubious records. Such records are usually old, often without supporting specimens, or with imprecise or possibly inaccurate labelling. Unfortunately, they often cannot be simply discarded because they might turn out to be valid, and have value simply because there are so little other data (for example, see Branch and Bauer 1992). In the introduction, as well as listing the new species they have added (seven of which have been described in the last 10 years, six by the authors), Trape and Mane briskly discard 15 species. Justifications for both additions and deletions are provided. The catalogue of deletions is fascinating and includes several species routinely listed for the Gambia, including *Lamprophis virgatus* and *Hapsidophrys smaragdina*, and, startlingly, *Rhamphiophis maradiensis*, described in 1991, which we learn was a misidentified *Malpolon moilensis*. With hindsight, in view of the lack of one-country endemics from this region, this is perhaps not unexpected. Consequently, whatever might be added in the future, the species featured in this book are what one might call the cast-iron, core snake fauna of the region. This book thus represents seminal literature.

I have a few complaints. Many of the illustrations are of dead snakes. This is unavoidable, you can't always find living examples of the species you want. If you want to illustrate every species

from your area, you will have to photograph a few dead museum specimens. In most cases here the photographs of obviously dead snakes are adequate for identification, pin-sharp, and of freshly killed or recently preserved specimens, retaining their original color. They are just aesthetically unpleasing, with misaligned or gaping mouths, sunken or dulled eyes, and curious postures. But it is disappointing to see magnificent animals like the cobras and mambas illustrated by lifeless corpses. The fine photographs of the rearing Egyptian cobra on page 195 and the alert *Cerastes* on page 208 show what can be done. Good pictures of living examples of a number of prominent species are in existence. I wish the authors had attempted to obtain these rather than relying so heavily on their own pictures of dead specimens. In addition, although burrowing asps, *Atractaspis*, do have very long fangs, the fang of *Atractaspis aterrima* illustrated on page 19 seems to me to be deceptively long; I suspect it has been dislocated.

The taxonomy here is largely conservative and very sound, but there are some decisions I find odd. Three new species of egg-eating snake are illustrated here, *Dasypeltis confusa*, *D. sahelensis*, and *D. gansi*. This last is what was regarded as a savanna form of *Dasypeltis fasciata*. However, I am not aware that the original paper (Trape and Mane 2006) has actually appeared. The egg-eaters are a complex and confusing genus, showing a huge amount of variation in both scale counts and color. Eminent herpetological taxonomists have struggled with the group, for example see Gans (1959 and 1964) and Hughes (1997). On present evidence I have my doubts as to the validity of *D. sahelensis* and *D. confusa*. The use of the generic name *Haemorrhois* for part of *Coluber* is indicative of the taxonomic morass that at present envelopes this widespread genus; it will be a long time before the debate is settled and it might have been worth sticking with the old name until the situation is resolved. There are also a few errors and typos (e.g., Bob Drewes has become Dewes on page 223, *Hemirhagerrhis nototaenia* is described as non-venomous on page 112, but it is rear-fanged). I am not sure I would agree with the authors' observations that the house snake, *Lamprophis fuliginosus*, is placid and easily captured and handled. It is harmless but in my experience these snakes are quick moving and bite savagely and rapidly when first captured.

I do not want to carp or nit-pick, however. The huge merits of this book far outweigh its minor shortcomings. It is well researched, well illustrated and, in these days of what I sometimes consider almost insanely high prices for herpetological books, relatively inexpensive. It makes the West African savanna and desert snake fauna accessible to the man in the street, and will be genuinely useful in the field. Most important of all, in the hands of medical professionals in West Africa, this book will save lives. In herpetological publishing, you don't get more useful than that.

Acknowledgments.—I thank Barry Hughes for helpful criticisms and information.

Reptiles and Amphibians of East Africa, by Stephen Spawls, Kim M. Howell, and Robert C. Drewes. 2006. Princeton University Press (press.princeton.edu). Softcover. 240 pp. US $24.95. ISBN 0-691-12884-7.

ELI GREENBAUM
Department of Biology, Villanova University
Villanova, Pennsylvania 19085, USA
e-mail: eli.greenbaum@villanova.edu

In the Introduction to *Reptiles and Amphibians of East Africa* (RAEA) the authors explain that their book is meant to be a portable field guide to identify the 190 reptiles and 85 amphibians (of their estimated 620 species total) that they feel the public are most likely to encounter in East Africa. The authors have certainly accomplished this modest goal with their photo-rich, lightweight, compact book (12.5 × 19 cm), which can

easily fit into a backpack or vehicle glove compartment.

Short (1–3 pages), illustrated subsections of the Introduction entitled "How to use this book," "East African reptiles and amphibians and their zoogeography," "Observing and collecting reptiles and amphibians," "Conservation," "Safety and reptiles," "Identifying reptiles," and "Identifying amphibians" orient the novice through basic information about East African amphibian and reptile morphology, biogeography, behavior and natural history. One-page introductions to the orders of reptiles and amphibians precede their respective species accounts. There are also one-paragraph descriptions of each family (and in some cases, suborders), including taxonomic notes, natural history, identification pointers and content in East Africa. The brief species accounts with photos are about half a page each, and convey basic information about identification (size, coloration, basic morphology), habitat and distribution in East Africa, and natural history comments. Other species are listed without photos and are limited to one or two sentences about identification and distribution. I counted 193 reptile species accounts with photos, nine species with photos mixed in with the 230 additional, abbreviated reptile accounts, 84 amphibian species accounts with photos, and two species with photos in the 85 additional, abbreviated amphibian accounts. Although the main focus of the book is on the East African countries of Kenya, Uganda, Tanzania, Rwanda and Burundi, some accounts include information about the surrounding countries of Somalia, Democratic Republic of Congo, Malawi, Mozambique, and Zambia. At the back of the book, the authors have included brief (1–3 pages) sections including a Glossary, Institutions involved with East African herpetology, Photo credits, Index of scientific names, and Index of English names.

For more extensive information, identification keys, and additional reptile species accounts, RAEA directs readers to *The Dangerous Snakes of Africa* (Spawls and Branch, 1995) and *A Field Guide to the Reptiles of East Africa* (Spawls et al., 2002). Herpetologists familiar with the latter book will recognize the exact same information and photographs in many of RAEA's reptile species accounts. The information has been condensed, and just over 75% of the photos are identical. The photographs range in quality from excellent to poor, consistent with a review of Spawls et al. (2002) by Branch (2002). However, many of the new photographs are of improved quality, and one snake (*Polemon christyi*) was not illustrated in Spawls et al. (2002) or *Snakes of Zambia* by Broadley et al. (2003). Nearly all of the amphibian photographs are original—only one of the amphibian photographs (*Hyperolius orkarkarri*) is present in *Treefrogs of Africa* (Schiøtz, 1999), and none seem to be identical to photographs in *Amphibians of Central and Southern Africa* (Channing, 2001) or *Amphibians of East Africa* (Channing and Howell, 2006). Moreover, RAEA illustrates six species (*Schoutedenella schubotzi*, *Hemisus guineensis*, *Phrynobatrachus irangi*, *Spelaeophryne methneri*, *Xenopus wittei*, and *X. victorianus*) that are not illustrated in the latter amphibian volumes, and 11 different color patterns of the highly variable *Hyperolius viridiflavus*/*glandicolor* complex.

In addition to the photographic benefits of the book, RAEA is sprinkled with interesting natural history information and creative descriptions of certain groups. Many readers will be delighted to learn about geckos that are known to steal bread and sugar from homes (*Lygodactylus picturatus*, pg. 39), a skink that can swim well in the ocean (*Cryptoblepharus boutonii*, pg. 48), a lacertid that can glide between trees when pursued by predators (*Holaspis guentheri*, pg. 52), chameleons that supercool (*Chamaeleo hoehnelii*, pg. 68; *C. rudis*, pg. 71), toads with internal fertilization (*Mertensophryne micranotis*, pg. 167; two species of *Nectophrynoides*, pg. 169), female frogs that can carry tadpoles on their backs (*Hemisus marmoratus*, pg. 173), and treefrogs with bile pigments in their circulatory system that stain its muscles, bone and blood green (*Leptopelis barbouri*, pg. 178). Some of the unique observations about certain groups include plated lizards that make "excellent, confiding pets" (*Gerrhosaurus major*, pg. 59), vipers that can form C-shaped coils and rub them together, "making a noise like water falling on a hot plate" (pg. 147), and my personal favorite—rain frogs (*Breviceps*) that "resemble badly made meatballs to which the chef has added a face and four legs" (pg. 218).

Because the writing of the book was completed in August, 2005, herpetologists should not look for recent, major taxonomic changes of amphibians (e.g., Frost et al., 2006). RAEA seems to have benefited from criticism of *A Field Guide to the Reptiles of East Africa* (Spawls et al. 2002) by Branch (2002) and Broadley (2002) in some cases. For example, the correction by Broadley (2002) of the genus of large tree agamas from *Acanthocerus* to *Acanthocercus* was incorporated, but the advice regarding the common name of *A. atricollis* was ignored. In a similar fashion, some but not all of the taxonomic changes suggested by Branch (2002) were incorporated, including the correction of a misidentified photo of *Mehelya poensis*. Taxonomic changes and species descriptions that were published recently have, in some cases, been missed or unincorporated (e.g., *Trachylepis* instead of *Mabuya*, Bauer, 2003; *Strongylopus kilimanjaro*, Clarke and Poynton, 2005).

I noticed that RAEA listed *Boulengerula taitanus* instead of *B. taitana*, which was spelled correctly by Channing and Howell (2006). The authors use the term paratoid gland (pg. 216) to refer to the lack of glandular tissue behind the eyes of *Tomopterna*, but this spelling should be used for similar glands in salamanders (Tyler et al. 2001). In frogs the correct spelling is parotoid gland, not parotid gland (salivary glands in mammals), which is used elsewhere in RAEA (amphibian features figure on pg. 16; pgs. 18, 162–71, 232). This book review would not be complete without the requisite listing of typographical errors, of which I noticed a few: "This is particularly useful identification pointers are the colours…" (pg. 6); "Most of their lives is spent buried…" (pg. 15); "A quick-moving gecko, with a round pupils…" (*Cnemaspis* accounts, pgs. 31–32); "recognized throughout sub-Saharan African…" (pg. 195); "with an isolated recorded from…" (pg. 206). Finally, I found it frustrating that none of the species in the abbreviated accounts are listed in the index.

These drawbacks aside, this book will be an informative, inexpensive, and practical field guide to herpetologists, other biologists, and tourists on safari in East Africa. Because this book is bound to be popular, and tourists surely uncover rare species from time to time, I was especially pleased to see the authors encouraging people to bring worm lizards (amphisbaenians) to museums (pg. 79) because they are harmless and poorly known. Professional herpetologists who are interested in East Africa and own a copy of *A Field Guide to the Reptiles of East Africa* (Spawls et al. 2002) will still want to pick up a copy of RAEA for the

unique amphibian photos and practical use in the field.

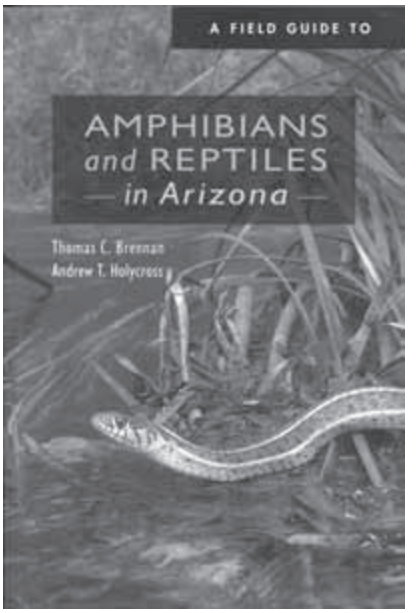
Artwork and Images Wanted for *HR*

We are always interested in obtaining illustrations of herpetological subjects for publication in *Herpetological Review*. Generally, original drawings should be of a scale that would permit reduction to fit a 90-mm wide column. Original art, or high quality photocopies, should be packaged to ensure safe delivery and sent to the Editor. Alternatively, we would be pleased to receive material in electronic format; consult the Editor for appropriate file formats and sizes.



Also, we are interested in evaluating outstanding color slides or high-resolution digital images of amphibians and reptiles for possible use on future *HR* covers. When reviewing material for submission, photographers should keep in mind the vertical format of our covers. In addition to highlighting outstanding photography, our cover subjects should lend themselves to communication of biologically interesting information through accompanying text. If you would like to have your work considered, please contact the Editor ***prior*** to sending any material. We prefer to review images as JPEG or PDF files before requesting examination of original slides. Postal and e-mail addresses are listed on the inside front cover.

Those of us old enough to remember the indispensable little green book—whether Conant or Stebbins—share a collective longing for its economy and ergonomic form. Into the glove box or backpack it would go, altogether unobtrusive and readily retrievable. True, back then we on the Eastern Seaboard dealt with just one species of slimy salamander while western colleagues enjoyed a monotypic *Rhyacotriton*. As our recognition of herpetological diversity grew, however, so did its documentation. And we watched our once slim, succinct guides become encyclopedic, lamentably unwieldy—more of a desk reference than anything suitable for the field. Enter the new *Field Guide to Amphibians and Reptiles in Arizona* by Thomas Brennan and Andrew Holycross, with one of its many appealing features—portability. At a modest 150 pages, the book is comprehensive without being cumbersome, the authors having struck a near perfect balance between content and utility.

Totaling 132 species, Arizona's rich herpetofaunal diversity is attributable to the region's interplay of geography, geology, and climate. Eight major biomes fall within the state, yielding 14 distinct biotic communities that range from tropical desert scrub to alpine tundra. Brennan and Holycross convey the significance of these communities to Arizona's natural history in a concise treatment of biotic community structure. Each community is profiled and illustrated by an accompanying photograph, and its overall distribution color-coded on a state map. In my view, this illustration may be the single most important figure in the book, as much of Arizona's herpetofauna is community-specific. To this end, the authors appropriately list those species common to each biotic community, and the community map provides a valuable cross-reference for the species distribution maps.

Species accounts are where this book really shines; much thought and effort apparently went into their layout with respect to function and aesthetics. The color plates are superb and beautiful to browse. Field guide plates can often be distractingly cluttered, but

not here. Turning page after page, I was struck by the clarity of the plates, each bearing images that seemingly draw you in, right to the key characters, clearly marked. Where necessary, particularly when diagnostic scalation is an issue, species photographs are supplemented with clean line drawings. For the few species with distinctly marked young (e.g., Barking Frog, Madrean Alligator Lizard, Eastern Racer), a photograph of the juvenile accompanies the adult. Ventral shots are included for the lizard genera *Callisaurus*, *Cophosaurus*, *Holbrookia*, and *Uma*, illustrating diagnostic patterns and/or coloration on the throat or belly. I was duly impressed by the photograph of the Zebra-tailed Lizard (*Callisaurus draconoides*) in characteristic field pose: tail upturned and arched over the back, revealing its black and white ventral barring.

Species accounts, set up on facing pages, opposite respective photographs, allow the reader to glance back and forth between the two with ease. Each species profile provides requisite information on size (mm and inches), description, occupied biotic communities, habitat specificity, and activity period. For the vast majority of species, details on diet, breeding season, and clutch or litter size are also given. A brief description of the call is included for the anurans. Where applicable, species are noted as being NON-NATIVE, PROTECTED, and/or VENOMOUS in colored-coded, bold font that prefaces the general text. Distribution maps, though small, are fairly detailed and color-coded to distinguish current (green) versus historic (tan) geographic ranges, as well as introductions (red).

Brennan and Holycross made every effort to incorporate the latest taxonomic updates, with attendant nomenclatural changes involving both common and scientific names. The section on common and scientific names outlines their justification for decisions regarding full specific status in some cases (Arizona Black Rattlesnake, *Crotalus cerberus*) and synonymy in others (*Rana subaquavocalis* is subsumed in *R. chirichauensis*). Many of the citations providing the phylogenetic justification behind these taxonomic decisions are conveniently listed in this section. The book's current taxonomy reminds us seasoned recalcitrants that we're just going to have to let go of *Cnemidophorus* and start thinking *Aspidoscelis* the next time we try to identify a whiptail in Arizona.

Current status is equally important from an ecological perspective, and Brennan and Holycross bring to light those species that are experiencing decline. One particularly disturbing case involves the Narrow-headed Gartersnake (*Thamnophis rufipunctatus*). This strongly aquatic snake, characterized by a distinctively tapered, gracile head, is a foraging specialist on many of the state's native fishes. Populations have undergone precipitous declines recently in both Arizona and adjacent New Mexico. Non-native fish and crayfish have been argued to account, in part, for this unusual species' unfortunate demise.

What better state field guide than Arizona's to include a section on envenomation. Here the authors offer a paragraph invoking common sense as the main operative for avoiding snake and Gila Monster bites, but provide "To Do" and "NOT To Do" first aid lists should such an incident occur. In their account on the Mohave Rattlesnake (*Crotalus scutulatus*), Brennan and Holycross underscore this snake's distinction in producing primarily neurotoxic venom and warn that populations inhabiting southeastern Arizona carry exceptionally potent neurotoxins. They also include a section on the Sonoran Desert Toad (formerly, the Colorado River Toad) as a potential threat to overly curious pets, given this toad's size and toxicity. Oddly, they do not mention Sonoran Desert Toads in the context of "toad licking" or the hallucinatory state its toxins can reputedly produce.

In keeping with the tenor of a field guide, the book includes a short though insightful section on viewing tips, a glossary, and checklist of scientific names, in which each name is followed by a short space for jotting down dates, locality data, etc. In summary, Brennan and Holycross have succeeded admirably in assembling a field guide that is delightfully accessible, one allowing readers —from the weekend naturalist to professional herpetologist—to identify Arizona's amphibians and reptiles quickly, easily, and reliably. No herpetologist should venture field-side in Arizona without one. In fact, take two—they're small!

PUBLICATIONS RECEIVED

Skin Diseases of Exotic Pets, edited by Sue Paterson. 2006. Blackwell Publishing, Ames, Iowa (www.blackwellpublishing.com). x + 333 pp. Softcover. US $74.990. ISBN 0-632-05969-9.

This book is intended for a veterinary audience and provides basic information on the diagnosis and treatment of skin diseases in a variety of vertebrates. Amphibians are not considered, but 65 pages are devoted to reptiles. An introductory chapter includes an overview of the basic structure and function of reptile skin, including normal histology and the process of ecdysis. General aspects of patient examination and diagnosis are presented, along with a basic reptile formulary. Separate chapters deal with skin diseases and treatments of snakes, lizards, and chelonians. Parasitic diseases, trauma, dysecdysis, neoplasias and both nutritionally- and endocrinologically-induced conditions are covered as are their clinical signs and recommended therapy. The book is illustrated by color photos throughout. Other sections of the text deal with fish, birds, and a variety of small mammalian pets, exclusive of dogs and cats.

Synopsis of Helminths Endoparasitic in Snakes of the United States and Canada, by Carl H. Ernst and Evelyn M. Ernst. 2006. Society for the Study of Amphibians and Reptiles (www.ssarherps.org). SSAR Herpetological Circular No. 34. 86 pp. Softbound. US $9.00. ISBN 0-916984-67-2.

Parasitic worms have been reported from 61% of the 131 North American snake species occurring north of Mexico. This small book provides both a synopsis of the helminths recorded from snakes and a list of worms organized by snake host species. The former list includes synonyms, habitats (the organs or regions of the host that harbor the worms), host species recorded, geographic distribution, and references. The later presents an alphabetical listing of worms by major taxonomic group (cestodes, trematodes, acanthocephalans, nematodes) and references. Many widespread snakes support a surprising diversity of parasites (e.g., approximately 50 species in *Nerodia sipedon*). A bibliography of nearly

450 entries comprehensively covers the scattered literature dealing with parasitic worms of North American snakes. Separate indices to the scientific names of worms and snakes conclude the work.

Ecology of the Acanthocephala, by C. R. Kennedy. 2006. Cambridge University Press, Cambridge, UK (www.cambridge.org). ix + 249 pp. Harcover. US $110.00. ISBN 0-521-85008-8.

This book is devoted to a relatively poorly-studied group of parasitic worms that are capable of damaging the intestines of their hosts. All 1000 or so acanthocephalans have intermediate arthropod hosts and definitive vertebrate hosts. They occur in terrestrial, freshwater and marine environments. Only 2% and 1.8% of known species have as their final hosts amphibians and reptiles, respectively. However, snakes, lizards, and frogs are commonly utilized as paratenic hosts (i.e., they eat the intermediate host and are in turn eaten by the definitive bird or mammal host, providing the parasite the opportunity to jump between trophic levels). This book is written from the perspective of the biology of the parasite, but the ecological relationships described are equally relevant to the host organisms, including amphibians and reptiles.

Emerging Threats to Tropical Forests, edited by William F. Laurence and Carlos A. Peres. 2006. University of Chicago Press, Chicago (www.press.uchicago.edu). xii + 563 pp. Softcover. US $40.00. ISBN 0-226-47022-9.

Emerging threats are dangers to biodiversity resulting from direct or indirect human action on the environment. Forty-nine contributors in 23 chapters discuss the impacts of several categories of these threats including climatic and atmospheric change, pathogens and invasive species, habitat loss and fragmentation, and fire. Solutions to these problems and means of mitigating threats are discussed in several chapters. Examples come from throughout the tropics, with an emphasis on the Neotropics and Central Africa. Although the focus of most contributions is on threats to forest biodiversity in a broad sense, some chapters focus on particular forest-dwelling taxa, such as primates. No chapters are devoted to the herpetofauna, but mention of tropical frogs and reptiles are scattered throughout the book and amphibian declines are a focus of the chapter on emerging infectious diseases. The broad regional or global nature of the environmental changes documented in this volume bear directly on the future of all tropical biota. The book is illustrated throughout with maps, graphs and black and white photos. A 79-page cumulative literature cited section provides an entry into the relevant environmental literature. This book will be particularly appreciated by ecologists and tropical biologists.

Amniote Paleobiology: Perspectives on the Evolution of Mammals, Birds, and Reptiles, edited by Matthew T. Carrano, Timothy J. Gaudin, Richard W. Blob, and John R. Wible. 2006. University of Chicago Press, Chicago, Illinois (www.press.uchicago.edu). vi + 547 pp. Softcover. US $40.00. ISBN 0-226-09478-2.

This volume honoring University of Chicago paleontologist James Allen Hopson comprises 15 contributed chapters by leading amniote paleontologists. These are arranged into four main subsections, as well as a biography and bibliography of Hopson. Three of these, "New Fossils and Phylogenies," "Large-scale Evolutionary Patterns," and "Ontogeny and Evolution" include chapters devoted to fossil reptiles. Among the taxa treated are dinosaurs (Theropod Dinosaurs from the Early Jurassic of Huizachal Canyon; The Origins of High Browsing and on Neck Length in Sauropodomorphs; Body-Size Evolution in the Dinosauria), plesiosaurs (Neoteny and the Plesiomorphic Condition of the Plesiosaur Basicranium), the early tetrapod *Whatcheeria deltae*, and a variety of mammals and mammal-like reptiles. Most of the contributions are data-rich and well illustrated by black and white photographs and line drawings. This volume will be of interest to those interested in functional and evolutionary morphology and in amniote phylogenetics, as well as to vertebrate paleontologists in general.

ERRATUM

In the article "The influence of body size and trophic morphology on the size of molluscan prey of female Texas map turtles (*Graptemys versa*)" by Collins and Lindeman (Herpetol. Rev. 37:416–418), the incorrect data were depicted in Fig. 3. The corrected Fig. 3 is shown here. A pdf reprint of the article, with the correct version of Fig. 3, is available from Lindeman (e-mail: plindeman@edinboro.edu).

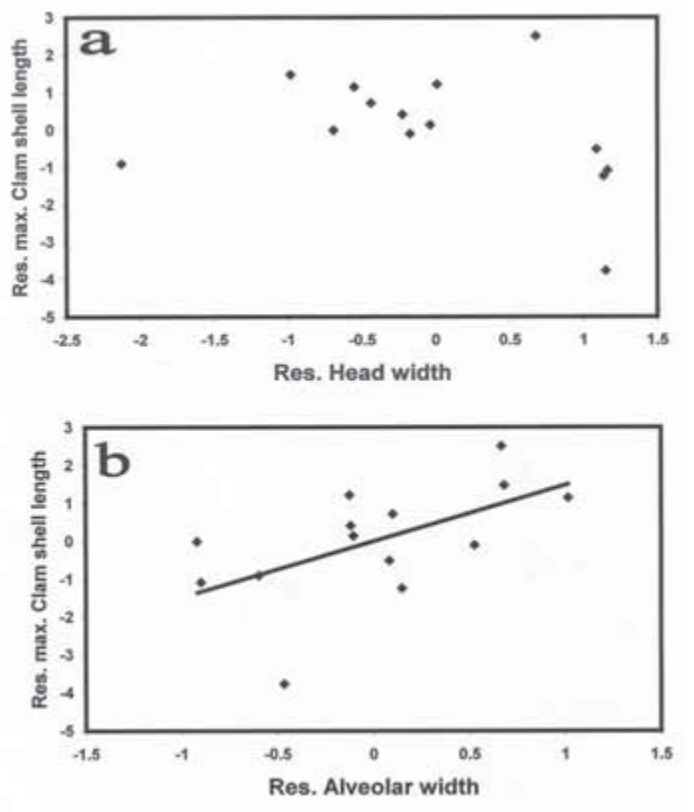

FIG. 3. Results of residual analyses testing (a) whether maximum shell length was related to head width (HW) after correction for both variables' log-log correlation with plastron length (r = 0.335, P = 0.24) and (b) whether maximum shell length was related to alveolar width (AW) after correction for both variables' log-log correlation with plastron length (r = 0.575, P = 0.032).

BIOLOGY OF THE BOAS AND PYTHONS

Edited by Robert W. Henderson and Robert Powell

Foreword by Richard Shine

- 448 pages
- 30 contributions by 79 authors
- Over 200 color photographs, maps, figures, and drawings

Biology of the Boas and Pythons (ISBN 978-0-9720154-3-4) is the product of a symposium (Biology of Boas, Pythons, and Related Taxa) held at the 2005 joint meetings in Tampa, Florida, and sponsored by the Society for the Study of Amphibians and Reptiles. This was the first attempt to bring together researchers actively working on some aspect of boa/python biology.

The symposium was a resounding success, and *Biology of the Boas and Pythons* represents a current assessment of our understanding of booid biology. Between the diversity of the peer-reviewed contributions and the literature reviews, this volume will become an essential reference for most future boa and python research.

Subjects range from molecular-based phylogenetic relationships and feeding mechanics to habitat selection, population dynamics, physiology of digestion and thermoregulation, infrared vision, and conservation. Henderson and Powell are to be congratulated in assembling this fascinating book.

William E. Duellman, University of Kansas

...the content of this book unambiguously demonstrates that boas and pythons often are excellent models for conducting high-quality laboratory and field-based research.

Thomas Madsen, University of Wollongong

...this book is a significant contribution and a must-read for herpetologists, snake aficionados, and all persons interested in the natural history of a poorly understood group of organisms.

Roy W. McDiarmid, Smithsonian Institution

The writing is top notch, the illustrations are of outstanding quality, and the end result is a major contribution to our knowledge of snakes.

Harry W. Greene, Cornell University

Biology of the Boas and Pythons *sets a new standard in snake biology and will remain the standard for many decades.*

Laurie J. Vitt, University of Oklahoma

The Value of SERVICE.

Receiving great service from an equipment provider is critical to your research...we know that at ATS. When others get rattled and slink away from service, ATS supports you with industry leading 98% on time delivery and the extensive herpetological experience of our consulting biologists and customer service professionals. Whether your next project crawls, slithers or hops, join researchers from around the world who are benefiting from the added value of ATS service, quality, capability and experience. Call or visit us online today.

A New Herpetological Circular from the Society for the Study of Amphibians and Reptiles

Herpetological Circular 35

A Review Of Marking And Individual Recognition Techniques For Amphibians And Reptiles

John W. Ferner

This circular is a complete revision of Ferner's 1979 Marking Techniques Circular. Techniques covered range from toe clipping, shell notching and paint marking to PIT tagging and Radio Telemetry. This is the only to-date marking manual currently available. A must for any herpetologist or field biologist .

iii + 72 pages, February 2007, ISBN 0-916984-68-0

Prices: Prepublication (*SSAR members only*)		After June 31, 2006	US $11.00
first copy -	US $8.00	**USA Shipping** : First copy	US $2.00
additional copies	US $6.00	Additional copies	US $1.00

Send orders to: Breck Bartholomew, SSAR Publication Secretary, P.O. Box 58517, Salt Lake City, UT 84158-0517, USA. *Telephone / fax* 801-562-2660; *email*: ssar@herplit.com. Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may be charged to VISA or MasterCard (Account number and expiration date must be provided). SSAR membership details and a complete list of Society publications can be obtained on request from the Publications Secretary.

Guia de Campo de los
Anfibios de Honduras
James R. McCranie & Franklin Castañeda

This first Spanish edition of the *Amphibians of Honduras* is completely revised and updated with description of 124 species in 38 genera and 10 families. Taxonomic keys are provided in English and Spanish. The color plates include photographs of 121 species and 24 habitats. Eighty-five dot distribution maps cover the distribution of all 124 species. An additional 8 maps illustrate physical and political characteristics of Honduras.

Published with the financial support of the World Bank and RANA.

Specifications: 320 pages, 80 color plates, 6 x 9 inches. Hardcover (ISBN: 1-932871-11-1) $20.00. **Shipping:** $4.00 within the USA, $9.00 non-USA addresses.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution or Natural History notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order form will be sent prior to publication. These are also available upon request from the Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pdf/Adrates.pdf).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at WCSU, Department of Biology, 181 White Street, Danbury, CT 06810, USA. Periodicals postage paid at Danbury, CT 06810 and at additional mailing offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Breck Bartholomew, PO Box 58517, Salt Lake City, UT 84158, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Please notify Breck Bartholomew, SSAR Publications Secretary (contact information below), regarding missing or damaged issues.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 760		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 760	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com.
